Ph. phoenicura G. and S. (= *noctis* Stgr.) (134 i). Ground-colour as in *sophistes*, lighter brown, *phoenicura*, traversed by numerous, darker, small transverse stripes; the red median band of *sophistes* is absent, but the end of the abdomen is broad red. Central America to Colombia.

Ph. mandosa Drc. Marking and colouring almost exactly as in the preceding, but larger, the ab- *mandosa*, dominal end not red and the under surface with a green lustre. Rio de Janeiro. Apparently rare.

Ph. arbuscula Mschlr. Similar to the preceding, above resembling a *Caria*, the marking above more *arbuscula*, faded, consisting of 6 transverse bands separated by spots, the 4th and 5th of which flow together in cellule 2. Beneath the greenish lustre is replaced by a dull, somewhat brilliant bluish black, the wings somewhat narrower. Described according to a ♂ from Paramaribo.

Ph. dukinfildia Schs. (134 i). This elegant animal from South Brazil looks differently at every habitat, *dukinfildia*. Nearly always recognizable by an orange belt cutting off the apical part and by a cell-end spot of the fore-

wing and a similar transverse stripe in the hindwing. In specimens from Castro in Paraná, a small fine transverse stripe is at the cell-end of the forewing; in specimens from Villaprudente in the State of São Paulo, a thick orange wedge stands here; in specimens from Ypiranga, the small band of the hindwing is as thin as a hair, almost obliterated etc. It is of no use to denominate all these forms. — Not rare.

bocchoris. **Ph. bocchoris** Hew. (134 i). Only an orange oblique band on the forewing, which is narrow and obsolete at both its ends, but better developed in *suavis* Stich. (134 i). South Brazil, rarer than the preceding species, but less local.

vittata. **Ph. vittata** Stich. Both the wings with a broad orange band running beyond the middle from the costa as far as in front of the anal angle. Amazon. I cannot decide whether this species not lying before me, as well as *suapure* Weeks (from Venezuela) being likewise unknown to me in nature, belong into this genus indeed.

crocostigma. **Ph. crocostigma** Bat. Shape as in *sagaris* (134 h, i), forewing speckled dark with black transverse streaks. On the hindwing a richly orange-coloured, oblong transverse spot runs through the disc. Guiana and Amazon.

apoplecta. **Ph. apoplecta** Bat. seems to be very similar to *crocostigma*; upper surface dark brown, speckled in blackish; near the border the dark spots form a submarginal row. Fringes at the apex white, otherwise black. From the disc of the hindwing to the inner margin runs a saffron-coloured spot; Rio Tapajoz.

basilissa. **Ph. basilissa** Bat. Black, in the cell of the forewing begins an orange band running to the anal angle of the hindwing; this band is indented at the cell of the forewing and at the inner side on the hindwing, which is not the case in *sagaris*. The animal hardly belongs into the same genus with *cingulus* etc., the body is strong and the shape of the wings already approximates that of *Symmachia* and *Caria* by the bulging costa of the forewing and the long straight inner margin of the hindwing. Was described as *Mesene*. Para.

sagaris. **Ph. sagaris** Cr. (♀ = *satnius*) (134 h, i). The typical form is rather small. In the ♂ an orange stripe begins directly above the middle of the inner margin of the forewing, running obliquely across the hindwing and also the abdomen, so that its middle is orange, the base and end, however, being black. The ♀ is entirely different, it has broad wings and only on the forewing an orange-yellow oblique spot. It is undoubtedly altered by mimicry, in the same way as also the ♀ of *Panara phereclus* looking quite different in the same sex; the model to both of them are presumably certain oil-secreting *Arctiidae*. Typical *sagaris* particularly come from Guiana and the Amazon. There occur, however, also larger specimens, as I took them

tyriotes. almost exclusively in South Brazil: this is the form *tyriotes* G. and S. (134 i). These generally have a narrower band extending on the forewing upwards in a twisted point beyond the middle of the forewing; but there are in South Brazil (probably also elsewhere) also specimens with a broader point ending more obtusely

majorina. in the forewing; these were again detached as *majorina* Stich. (134 h *), I remark yet that another sexual dimorphism consists in the oblique band of the forewing appearing in the ♀ also beneath, though that of the ♂ does not show through, the ♂ being beneath entirely black, only with a light (unscaled) inner margin of the forewing. — The name of *matronalis* Stich. seems to refer to an aberration of the ♀, in which here

phrygania. or there a small ochreous spot appears on the hindwing. — ab. *phrygania* Stich. from São Paulo in Brazil has narrower bands, otherwise like *satnius* (*majorina* Stich.), but the bands of the ♂ are still broader than in specimens from Curitiba. — The *sagaris*-♂♂ fly in the shade of the woods, on narrow roads, where the rays of the sun pierce the leafy roof. I took them near Santos at two places where, whenever I passed there, I always saw one male dancing about, which whenever I had captured it, was always replaced again on the next day by another flying at exactly the same place; I obtained the ♀♀ only on ransacking the bushes along the same road.

iasis. **Ph. iasis** Godm. (134 i). Larger than *sagaris* and easily discernible by the orange stripe on the hindwing not extending as far as to the posterior margin nor across the abdomen, but terminating obtusely soon below the middle of the hindwing. Besides the wings exhibit a beautiful dark-blue reflection on both surfaces. Of course, the same variations occur here as in *sagaris*; thus, for instance, the spot of the forewing in the specimen I figured is much rounder than in the one from GODMANS collection, figured in the Trans. Ent. Soc. Lond. 1903 t. 22 fig. 7. Whoever wants to disseminate diverse names as this has been done in *sagaris*, may introduce further denominations here.

pluto. **Ph. pluto** Stich. (142 b). Shape and size like in the preceding; but above in the middle of the hindwing there is a large hemochrome spot and the back of the abdomen is of a bright hemochrome behind the middle. Colombia.

* According to an investigation having been published in the meantime, STICHEL corrects his former explanation of this species by stating that *satnius* Dalm. does not represent the ♀ of typical *sagaris*, but that of his *majorina*; so that the name of *majorina* Stich. would have to be replaced by *satnius* Dalm. *tyriotes* G. & S. is said to be a form of *crocostigma*, without the orange band of the hindwing. — STICHEL supposes our figure of *tyriotes* (134 i) to be approximating *satnius* Dalm. (his *majorina*). In fact, the original was collected only 3 hours by train from the finding-place of typical ♂♂ of *satnius*, near São Paulo. From Curitiba there is a specimen before me (Paris Museum), in which the orange band is still narrower and, at the anal part of the hindwing, entirely obliterated; the more attempts are made to denominate all these deviations of the habitats, the greater grows the confusion.

53. Genus: **Cricosoma** Fldr.

The species of this genus are closely allied to those of the following, but they differ from the *Symmachia* by the costa of the forewing (particularly of the ♂♂) not being bulged out. The name of *Cricosoma* may by no means disappear, as long as only one species described as *Cricosoma* is regarded as belonging to no otherwise denominated genus. But besides, the forms described as *Cricosoma*, maybe with some exceptions, form a very well distinguished group which would at least have to be maintained as a subgenus.

C. irrorata Godm. (142 g). This species, unknown to me in its free state, and described from the *irrorata*. Carimang River in Guiana, is the smallest of the genus; the ♂ is dirty yellowish grey, at the margin lighter, both the wings dotted in blackish. According to STICHEL, the 1. subcostal vein of the forewing touches the costal for a short distance; this, however, is only an effect of the costa forming a crookback, the expanding precostal area pressing the costal near to the subcostal veins; this is a slighter degree of the development as we find it in the following genera in a still greater measure. The species seems to be rare, maybe because the resemblance to the *Charis*-species (*chaonitis*, *argyrodes* etc.) occurring in crowds in the same country makes it difficult to discover them.

C. eraste Bat. (142 g). Smaller than the *irrorata*, the apex of the forewing more pointed, the colour *eraste*. dull red-brown, the black dots arranged more in transverse rows. According to STICHEL, the identification of the figure in the British Museum copied by us has taken place with BATES' original. Teffé on the Amazon.

C. batesi Stgr. (128 h). Somewhat larger than the preceding, the forewings not pointed at the apex; *batesi*. the dark spots in some places converge forming blackish clouds. Discovered by Dr. HAHNEL near Coary on the Upper Amazon. — **punctata** Btlr. differs probably only by a somewhat different arrangement of the *punctata*. dots on the upper surface. — Both occur in the Amazon district.

C. hippea H.-Schäff. (135 d) is an extremely variable species, the ground-colour of which is entirely *hippea*. blackish-brown, but it may also be so much interspersed with brownish-red that the upper surface appears almost red. It is always recognizable by the small light oblique band of the forewing which, however, runs sometimes more steeply, sometimes more flatly. Guiana. Not rare.

C. phaedra Bat. (135 e). Bright orange-red; the black small dots do not form any clouds, but they *phaedra*. grow somewhat larger towards the distal margin and represent thin transverse streaks in the cell of the forewing. In the forests of the Rio Tapajoz.

C. asclepia Hew. (128 h). Very much like the preceding, but the dark dots are absent in the disc *asclepia*. of the upper surface of the wings. Ecuador. — In **xypete** Hew. (128 h, 135 b), being somewhat larger, the *xypete*. dots are combined to distal-marginal chains or costal transverse streaks of the forewing, sometimes more, sometimes less. Here the ♂ is mostly darker red than the ♀. Central America. Rather common.

C. leopardinum Fldr. (128 e, as *leopardina*). Bright ochre-yellow, the black transverse streaks in the *leopardi-* costal part of the forewing still more abundant and dense than in *xypete*, but also the other surface of the *num*. wings densely covered with black dots. Bahia; rare. — **hilaria** Hew. Here the crowds of black dots become *hilaria*. condensed in the apical part of the forewing to a black cloud. From the Amazon.

54. Genus: **Pachythone** Bat.

The *Pachythone* are so easily recognizable that scarcely one of them has ever been brought into a wrong genus; in the *Erycinidae* this fact is rare and a proof for this genus being one of the most natural. Though the body is small, it is of a very clumsy structure; the head and thorax are almost globular, the abdomen relatively stout and short; the antennae shorter than in nearly all the other genera and at the ends with a short, knob-like, small club; the palpi are also short, with a very short, relatively stout terminal joint; the veins do not exhibit any peculiarities except the cell of the hindwing, which is otherwise short in many *Erycinidae*, being here almost as long as that of the forewing. — The *Pachythone* are mostly very rare butterflies, not differing in their habits, as far as is known nowadays, from the allied genera. In the structure of the body, they somewhat resemble *Mesene*, but also *Syrmatia* and *Symmachia*.

P. erebia Bat. (142 i) is a small, above jet-black butterfly with white fringes of the hindwing. Under *erebia*. surface paler, likewise without markings. Amazon. Rare.

P. pasicles Hew. (142 i). Dark brown, the margin of the forewing lighter with a series of dark dots. *pasicles*. Forewing above with dark transverse dots in the basal part and a curved stripe beyond the middle, hindwing with 3 shortened stripes in the basal part, 3 transverse stripes crossing the distal part of the wings, and a dark border. Beneath like above, the transverse stripes are absent or broken up to strigiform dots. Espiritu Santo. Rare.

P. palades Hew. (142 i). Sooty blackish-brown, darker markings than in *pasicles*, besides a light-yellow *palades*. oblique band of the forewing. South Brazil, rare. — **philonis** Hew. is quite a similar species from Colombia *philonis*.

and Panama, but the dark bands of the hindwings are not distinctly noticeable, and the oblique band of the forewing is narrower, beneath more pointed and more orange than bright yellow.

mimula. **P. mimula** Bat. In the inner half of the dark brown forewings stands a yellow triangle, and in the middle of the apical half a yellow longitudinal spot. The basal part of the hindwing is yellow as far as beyond the middle of the wing, this colour bending in into the dark distal margin; thus the appearance, so very favourite in South America, of one of the black-yellow *Cyllopodina* results therefrom. From Santarem.

gigas. **P. gigas** G. and S. (142 k). ♀ similar to the preceding, larger, the yellow increased, so that the appearance of certain Heterocera (*Atryia isis*, *Flavinia postica* etc.) is produced. ♂ more rusty-coloured Panama. Distinguishable from similarly coloured *Aricoris*-♀ by the short palpi.

thaumaria. **P. thaumaria** Stich. As large as *coccineata* (142 i), miniate with a black margin of the wings and a black, white-pupilled apical part of the forewing. It resembles certain *Mesene*, though secondarily; the model for both may be small, *Endule*-like Heterocera, flying in day-time and being rather common.

xanthe. **P. xanthe** Bat. resembles the preceding, but the colouring of the ground of the wings as well as of the apical pupil is saffron. Border of the hindwing narrow, irregular. From the black costa of the forewing 2 black triangles penetrate the cellular space. Teffé.

distigma. **P. distigma** Bat. Dark brown; in the hindwing, between the cell and border, is a rusty-brown transverse spot, not reaching the inner margin. This spot is obliterated on the paler-coloured under surface, but here we notice in front of the border a series of dark dots in a light area. Size like that of the preceding species. It resembles *Phaenochitoniu crocostigma*.

ignifer. **P. ignifer** Stich. is described according to a ♂ from the Rio San Juan in Colombia. Wings above reddish ochreous yellow. Forewings at the costal margin and border rather uniform, at the apex bordered more broadly. Here a circular patch of the ground-colour is cut off by an oblique stripe from the costal margin to the border; the border of the hindwing is black, bending somewhat round at the apex and inner margin. Under surface more light yellow.

lateritia. **P. lateritia** Bat. (142 i). Above brick-red, sometimes more sparsely, sometimes more copiously covered with small dark dots being arranged into straight rows in the basal part and in front of the border and forming a curved chain behind the cell. Under surface (♀ also above) with a dark distal margin of both wings.

coccineata. Northern parts of South America. — **coccineata** Kaye (142 i) I figure according to a specimen from Tabaguite (Central Trinidad). Here the disc of the forewing is above almost unspotted. Similar specimens occur also at certain places of the continent. Guiana-specimens are often very small.

55. Genus: **Symmachia** Hbn.

This genus is distinguished by a strong bulging-out of the costa of the forewing of the ♂♂, this characteristic bulge recedes in but few species, presumably owing to a mimetic transformation. This widening of the forewing is accompanied by a peculiar flight resembling that of *Thecla*, which becomes very conspicuous in the non-mimetic species, whereas in the mimetic species it is replaced by that of the casual originals to which reference is made in the single species, and which may more correctly be eliminated from the genus. They are more closely allied to the *Cricosoma* than the non-mimetic species, but we shall here give the precedence to the more typical forms. Many *Symmachia* are great rarities, and they are extremely peculiar in the shape as well as in the colouring. Of many there exists but one specimen in collections, for what reason our illustration of this genus is mostly composed of copies according to FELDER, HEWITSON etc. They fly in day-time, not continuously, and rest beneath leaves.

A. Non-mimetic species: Costal margin of the forewings bulging out in the basal part.

tigrina. **S. tigrina** Hew. (128 e). Similar to *Cricosoma leopardinum*, like the latter yellowish-red ochreous, the black costal transverse streaks flow several times together; in front of the border black dots. The convexity of the base of the costa being in reality great, is not prominent enough in our figure. — In *virgatula*. **S. virgatula** Stich. the apical transverse stripes are confluent; Rio San Juan (Colombia).

suevia. **S. suevia** Hew. (128 e) is a species (or subspecies) similar to the preceding, the black marking being arranged to marginal rays also before the border.

arion. **S. arion** Fldr. (128 f). Considerably larger, the transverse streaks in the costal part of the wings rather straight, in the disc of the forewing dark shades, below the costa of the hindwing a broad, yellow ray. The patria of the only specimen (which I saw in the Tring Museum) is not exactly stated.

stigmatosissima. **S. stigmatosissima** Stich. seems to be allied to *tigrina*, but to be also similar to *Cricosoma leopardinum*. The species is said to be dotted like the latter, but to have black triangles at the costa of the forewing.

Under surface silky smoke-brown, dotted. The diagnose does not state whether the costa of the forewing is sinuous, as in *Symm. tigrina* or uniformly round (as in *Cricos. leopardinum*). Not lying before me. Bolivia.

S. virgaurea Stich. (142 c). Similar to *virgatula*, but whereas the latter has a more red-brown ground-colour, that of *virgaurea* is brighter red, so that it reminds us of our *Chrysophanus virgaureae*. The apical area of the forewing broad, the border narrow black. Between the 4 coniform, costal transverse stripes a fine striation. Larger than *tigrina*. Colombia.

S. praxila Ww. (128 g). Bright yellow dotted on a black ground, the small spots next to the base and border of the forewing red. The most conspicuous of it is the colouring of the hunch of the base of the costa, which seems to represent plastically a thick, curved appendage, looking like a feathered antenna laid over the costal margin of the forewing. South Brazil.

S. norina Hew. (128 g) greatly resembles the preceding, but it is smaller, the fine markings sparser and duller yellowish instead of white. Amazon.

S. calligrapha Hew. stands in the middle between the two preceding species, with respect to the size as well as to the copious light small spots. From the Rio Tapajoz; a somewhat duller spotted specimen from Guiana was regarded as the ♀ of the species.

S. calliste Hew. (128 h, as *hippea*) already resembles the following species *cleonyma* by most of the tiny spots of the upper surface being coloured in a bright red-brown; only above, at and below the cell-end they are yet of a light colour. — A somewhat smaller form of another flying-place, which, however, is not to be denominated and represents a transition to *norina*, we have figured 128 h; it was by mistake denoted as „*hippea*“ on the table, Brazil.

S. cleonyma Hew. (128 h). All the small spots of a bright red-brown; but besides the disc of the hindwing is rather extensively brightened up by red-brown. We figure a specimen from Nicaragua; HEWITSON supplies a rather deviating figure; we reproduce the copy of it 134 g, which was by mistake denoted as „*calagutis*“ on the table. — **leena** Hew. (128 g) is somewhat smaller, but otherwise quite similar, some of the small spots of the upper surface ring-shaped, as for instance at the base and anal angle of the forewing. Likewise from Nicaragua *). — **harmodius** G. and S. from Colombia is like *leena*, but the forewing without spots, the brown cloud in the hindwing, however, distinct. — **multesima** Stich. from Colombia is said to be similar, but to have a whitish costal spot, and in the forewing (like *leena*) a red-brown area.

S. pardalis Hew. resembles *praxila* (128 g), but it is very much more densely and brightly coloured in a reddish yellow, with red-yellow, small transverse bands in the costal part of the forewings. In the disc of the wings the small spots are lighter yellow. — The last 9 forms, together with **juratrix** Ww. being unknown to me in nature, are undoubtedly very closely allied to each other. Most of them are of only one very narrowly circumscribed flying-place, and known only in 1 specimen, and it is not unlikely that they are modifications of very few widely distributed, but throughout rare species.

S. menetis Drury (= *tacitus* F.) (128 d). A great part of the forewing and the whole hindwing bright red, the costal part of the forewing black with white spots. In the ♀ (= *eurina* Schs.) the red runs before the distal margin towards the apex. An extremely conspicuous butterfly already resembling in the flight certain Lithosiids (which are also imitated by Microlepidoptera) in which, however, the proximal half of the wings is red, the distal part being black and white, so that the resemblance disappears in the resting animal. South Brazil. — In **piliarius** Stich. (128 d) the black in the wing is increased, particularly the dark border of the hindwing is broader. Likewise in South Brazil. — The species is very rare.

S. rubina Bat. (= *irata* Stgr.) (128 d). The black-white part in the forewing towards the red not straight, but irregularly defined, moreover, the base of the forewing is broadly black. Mexico to Colombia. — In **technema** Stich. (128 d) from Guiana the hindwings are still broadly margined in black. — The latter is also the case in **maeonius** Stgr. from the Amazon, but here the black-white part of the forewing is so much developed that the bright red is confined to the inner-marginal part of the forewing. — Very rare.

S. titiana Hew. (128 f) is orange-yellow, with black margins of the wings and a black costal triangle embedded with white on the forewing. Ecuador. Very rare.

S. arcuata Hew. (128 e). The red is here more miniate and confined to the inner marginal part and the disc of the hindwing. In the black part of the forewing only sparse, small white spots. Amazon.

S. hetaerina Hew. (128 e), originating like *arcuata* from the Amazon, is a very closely allied species or form, in which the inner spot of the wings is dull bone-yellow. — **hesione** Stich. has the median area pale ochreous or pale reddish; Upper Amazon. — Rare.

*) GODMAN and SALVIN call our attention to a hair-pencil in the middle of the costal margin of the hindwing, by which *leena* is said to be distinguished from nearly all the other *Symmachia*.

- threissa*. **S. threissa** Hew. (128 e) is a larger species, the forewings without red, only in front of the cell-end a white cuneiform spot; in the hindwing the cell is red-brown. Nicaragua. Rare.
- jugurtha*. **S. jugurtha** Stgr. (128 f). Forewing black with much white forming in the centre of the wing a large costal triangle and behind it a macular band. The inner margin of the forewing and 2 thick rays in the hindwing bright red. Colombia. Rare.
- aconia*. **S. aconia** Hew. has the red inner marginal stripe of both wings like in *jugurtha*, but the white in the black forewing is reduced to some minute splashes, and the red wedge below the costa of the hindwing is absent. Bolivia. Rare.
- miron*. **S. miron** Sm. has the forewings quite similar to *jugurtha*, but the hindwing is uniformly red, only narrowly margined in black. Ecuador.
- accusatrix*. **S. accusatrix** Ww. (128 f). Forewing black (♀ blackish brown) in the costal part very much spotted in white. The ♀ has white and reddish dots in the disc, in the ♂ the costal part of the hindwing is scarlet red. Central America to the Amazon. Rare.
- probetor*. **S. probetor** Stoll (= *probetrix* Hbn.) (128 g). Quite black, only in the middle of the costa of the forewing a small white wedge, and along the costa of the hindwing a red stripe. — In the form **astiana** form. nov. *belli*. (128 g) the white is absent in the forewing; from Guiana and the Amazon. — In **belli** G. and S. being somewhat smaller than typical *probetor* the ♀ has reddish-yellow, instead of white, small spots in the forewing. Colombia. I do not know of any authentically patented model to this species, but in the form *astiana* (with quite dark forewings) the species already resembles some other *Erycinidae*, such as *Euselasia gelon*-♂ (= *sabinus* Stoll, t. 121 b) and *Xenandra heliodes*-♂ (131 i).
- championi*. **S. championi** G. and S. greatly resembles *probetor*, but the forewings are more blackish-green with a black-spotted base; the ♀ is on the whole darker. Mexico and the adjoining parts of Central America. Rare.
- falcistriga*. **S. falcistriga** Stich. (128 g) flies on the Lower Amazon and in Guiana together with homochromous *Caria*-species. It is black, above with a greenish lustre, hardly well discernible from a *Caria*. Thus the two last-mentioned species form the transition to the mimetic forms. The figured specimen of this species is in the Paris Museum and originates from the Maroni River.

B. **Mimetic species.** Forewing longer, more pointed, the costa bent uniformly.

- triangularis*. **S. triangularis** Thm. (128 h). By the oblique orange stripe on the black ground of the forewing it reminds us of numerous smaller *Arctiids* with the same scheme of colouring, and of just as numerous imitators of these *Arctiids*, several of which belong to the *Erycinidae*, but apparently also *Geometrids* which otherwise supply but few examples of mimicry are concerned in this imitation. Colombia.
- tricolor*. **S. tricolor** Hew. (128 g). Beside the median band running across the abdomen (as described in *sagaris*), we find here yet 4 small orange distal bands. Amazon and Colombia. — **hedemanni** Fldr. (= *niciades* Bsd.) (134 i) has all the bands lighter yellow and the distal ones shortened to oval spots. Central America. — These forms are homochromous with *Heterocera* as well as with *Erycinidae* from the genera *Baeotis*, *Nymphidium* etc. Rare.
- rita*. **S. rita** Stgr. (128 g). In the exterior it resembles *falcistriga* above, but the costal part of the hindwing exhibits a lustrous blue, whereby it becomes similar to certain *Thecla*, and, of the *Erycinidae*, to certain *Euselasia*. The tiny animals are rare. Beneath they resemble, like the somewhat similar *S. falcistriga*, certain species of *Charis*. The figure has been done according to a specimen from Iquitos.

56. Genus: **Caria** Hbn.

In the shape of the compact, robust body and of the costa of the forewing projecting arcuately before the middle, in the flight and habits, as well as in the veins of the wings, there is hardly any difference to be noticed between this genus and the chief group of *Symmachia* (i. e. those species that are not deformed by mimicry). GODMAN and SALVIN, however, emphasize differences in the sexual organs of the ♂♂, and ever since the two genera are separated afar in the catalogues. The *Caria* generally have a dark upper surface which, however, is more or less ornamented with golden scales of a magnificent green reflection; the under surface sometimes exhibits a conspicuous red, particularly in the cell of the forewing. The ♀♀ show a decided relationship of the genus with the *Emesis* which, however, deviate from them in a different direction of development, from the previously mentioned *Mesene*, so that the relationship cannot be described in a continuous line. The *Caria* described hitherto are probably only vicarious forms of few species. The animals sit, with their wings spread, on sandy banks and are rather timid.

- mantineia*. **C. mantinea** Fldr. (135 e). Beside *lampeto* the largest species. Above at the base of the forewing and in the disc dusted with a metallic bluish-green, and a faintly lustrous, straight line before the distal margin. Of a brighter bluish-green lustre is an undulated submarginal cloud at the hindwing. Under surface sooty

blackish-brown; cell of the forewing red, above it (in the bulged-out costa-bow) and behind it (behind the cell-end), at the apex and between both, metallic spots. Before me from Bolivia (Province of Sara) and from the Coll. BANG-HAAS from the Pachitea; described from Ecuador. — **amazonica** *Bat.* has a more copious metallic scaling, particularly beneath, where often the whole cell of the forewing is embedded in metallic spots, whereas the red in the cell is somewhat reduced; from Teffé.

C. lampeto *G. and S.* (135 f). Above almost exactly as the form *amazonica* of the preceding species, beneath, however, the metallic scaling is reduced to faint traces above the cell and maybe a small faint spot at the apex. Central America to Bolivia. Not rare, particularly near Muzo in Colombia.

C. trochilus *Er.* is smaller than the preceding, the ground-colour of the upper surface blacker, beneath there is no red in the cell of the forewing, but in the costal part are numerous metallic spots, especially also in the cell of the forewing itself. Guiana. — **arete** *Fldr.* (135 f) has the same under surface, but above less gold which is more prominent almost only in the anal part of the hindwing; the submarginal metallic line of the forewing is absent altogether; Amazon to Peru and Ecuador.

C. castalia. The most common form is **marsyas** *Godm.* (135 e) recognizable by the under surface of the forewings, where the cell being filled out with red is interspersed with small metallic spots. Above similar to the preceding species, but with a faint metallic line before the border. South Brazil and Paraguay. In the typical **castalia** *Men.* (*tabrenthia* *Schs.*) from Brazil and Peru the ♂ has no red at all in the cell of the forewing beneath. — ab. **philema** *Stich.* is the name of a specimen with a red-yellow stripe beneath before the border. — **smaragdina** *Godm.* (135 e) is above very brightly scaled in green, the light metallic stripe before the border on the forewing broad; under surface without red in the cell of the forewing. Bolivia. — The species is not rare.

C. colubris *Hbn.* (= *paridion* *Dalm.*, *argiope* *Godt.*) (135 f). Easily recognized by the bridge which runs through between the green of the base and the disc on the middle of the forewing being narrow, jet-black and filled up narrowly with brown. Before the apex mostly a bright orange spot. Beneath similar to *lampeto*. — ab. **fulvimargo** *Lathy* (135 e) is the denomination of a light specimen being bordered by orange-yellow above on the hindwing, beneath also on the forewing; a colouring often occurring in the ♀♀ of the other *Caria*-species. Interior of Brazil to Peru. — In **plutargus** *F.* STICHEL presumes a ♀ of „*argiope*“; the figure of this form, being supplied by DONOVAN, exhibits a rough dotting which presumably scarcely answers to nature. Brazil.

C. domitianus *F.* (135 f) has on the upper surface of the forewing the golden green exactly in the middle of the wing, i. e. at the place, where it is absent in *mantinea*, *lampeto* etc. Easily recognizable by the yellowish-red under surface exhibiting metallic spots in the costal part of the forewing, while it is otherwise covered all over with black spots. Guadeloupe. — **ino** *G. and S.* from Mexico deviates especially by the absence of all the golden green scales on the upper surface; — **melicerta** *Schs.* which extends still farther to the north as far as Texas, with very few dispersed golden scales, forms a transition between the two forms; — **galbula** *Fldr.* is, on the contrary, the southern form, described from the Province of Caracas (Venezuela), looks above almost like a small *castalia*, but is immediately distinguished by the red-yellow under surface. In this form the golden-green strewing of the upper surface is the most copious.

C. rhacotis *G. and S.* (135 f) exhibits in the median area of the forewing an accurately defined, irregular spot of a golden green lustre; the under surface is deeper red-brown, particularly in the ♂, with black dots of which those along the costa of the forewing exhibit a dull leaden lustre. Honduras to Colombia. — **harmonia** *G. and S.*, described according to 1 specimen, from the Isthmus, may only be an aberration without the leaden spots on the under surface along the costa of the forewing.

C. stillaticia *Dyar* (143 e, f). Upper surface almost quite blackish brown with jet-black spots; metallic bluish-green scaling is noticed almost only in the anal region of the hindwings, and a metallic line may run along in front of the border of the hindwing or also be absent altogether. Very characteristic is the dark red-brown under surface by nearly all the black spots of the hindwing and all those of the costal half of the forewing being brightly centred in silver. Mexico; the specimens before me originate from Guerrero.

C. melino *Dyar.* Dark leaden grey with tiny black spots of a greenish lustre. Forewing with a spot in the cell, behind the latter a series of small spots and in front of the border a double row. On the hindwing dispersed small spots scarcely forming a row, whereas the double submarginal row is almost formed by lines between which there is a copper-like tinge. Under surface dull red, the spots like above and more distinct, scattered across the base of both wings; above the apex of the forewing lies a broad shade and a narrow one runs along the border of the hindwing; the inner margin of the forewing grey. 22 mm. Tehuacan in Mexico; discovered in 1911 by ROBERT MUELLER.

C. chrysame *Hew.* (135 g). Distinguished from all the species enumerated so far by the fact that not the median area but the whole wings are above coloured in golden green; only the marginal area is blackish grey, bordered by bright bluish-green metallic lines, of which the outer one is as fine as a hair, sometimes interrupted in typical specimens from Bolivia; — in Peruvian specimens — **psittacus** *Hpfpr.* (= *scurra* *Stgr.*) — it is broad and distinct, almost like in *sponsa* (135 g). Under surface earthy-grey with rows of dark dots which may be numerous and distinct, but also be absent. Common.

sponsa. **C. sponsa** *Stgr.* (135 g). Similar to the preceding, but also the distal area is golden green, except a narrow border, a dark submarginal line and a dark large spot before the apex of the forewing. On the Jurimaguas.

57. Genus: **Chimastrum** *G. and S.*

The small, delicate butterflies of this genus consisting of but 2 species exhibit an alliance to the *Mesene* and *Esthemopsis*, and are placed before the *Symmachia* by STICHEL *). They differ from these two groups by white wings of a silken gloss, from the latter genus by the gently curved, not bulged-out costa of the forewing. The body is more delicate than in *Caria* and *Esthemopsis*, approximating more the *Baeotis*.

argenteum. **Ch. argenteum** *Bat.* (= *hewitsonii* *Bsd.*) (128 b). Silky-white with a rusty-yellow base of the wings and a black margin. Central America, particularly on the Chiriqui; single, though not rare.

carnutes. **Ch. carnutes** *Hew.* (128 b, as *carnutus*). Silky white, from the black distal margin black tips extend towards the base, two of which intersect each other in the shape of an X on the forewing. Colombia, not common.

58. Genus: **Baeotis** *Hbn.*

Tiny, black and yellow, sometimes also white and black butterflies flying about in the sunshine during day-time, with a delicate body, a somewhat projecting apex of the forewing and an extraordinarily short cell of the hindwing, which is not even half as large as the cell of the forewing. About a dozen of species are known.

felix. **B. felix** *Hew.* (134 f). White with a broad black border, the lemon-coloured base of both wings separated from the white ground-colour by a black stripe (from the middle of the costa of the forewing to the middle of the inner margin on the hindwing. Bolivia and Peru). — In *felicissima* *Thm.* (134 f) from Ecuador a lustrous light-yellow line runs through the black margin. — A specimen in FASSLS collection, from Co-roico in Bolivia, has a lemon-coloured ground-colour, without any white at all; I call it ab. **citrina** ab. nov. — Not rare.

nesaea. **B. nesaea** *G. and S.* (134 f) looks like the ab. *citrina* of the preceding species, but it is somewhat smaller and has a twice as broad black margin traversed by a yellow thin stripe running between 2 metallic lines. Costa Rica, Chiriqui. — **bacaenita** *Schs.* (134 f) exhibits the yellow median area narrowed, particularly in its costal part of the forewing, but otherwise it is allied to *nesaea*. Peru and Bolivia, taken yet at an altitude of 300 m on the Juambari. — **euprepes** *Bat.* from the Rio Tapajoz is not before me; it has likewise 3 yellow stripes through both wings, the foremost of which, however, is more remote from the base of the wing.

bacaenita. **B. bacaenita** *Hew.* (134 f). Smaller than the preceding, the yellow basal stripe and the submarginal line as thin as a thread, the median area of both wings forms a white, conjoint oval. Ecuador. — **elegantula** *Hpffr.* (134 f) scarcely differs, the stripe at the base more ochreous-yellow as well as the line in the black distal margin, this line being expanded towards the costa of the forewing. Peru and Bolivia. — Common.

prima. **B. prima** *Bat.* This species, not lying before me, has likewise 3 yellow transverse stripes; the first runs along the inner margin of the hindwing, the middle stripe being oblique, the subapical one fine. On the under surface one yellow stripe in addition and the outer one in the anal part of the hindwing forked. One of the largest species. The forewings have a complete metallic line before the border. From the Rio Tapajoz. — This species is perhaps approximated by **orthotaenia** *spec. nov.* (134 f) from Bolivia, in which, however, the median stripe in the forewing stands straight, while the hindwings have a metallic line before the border, the forewings, however, only indications of such a line before the apex. — **dryades** *Dogn.* is presumably also allied to this species, but it is smaller, the median stripe reaches neither the costa of the forewing nor the inner margin of the hindwing, it is strangulated in the middle, while the distal stripe is intersected in such a way that it is broken up on each wing into 2 spots (near the costal margin and the inner margin).

creusis. **B. creusis** *Hew.* (134 e). Very easily recognizable by the common median stripe being white, above and below tapering and slightly bent like an S. Bolivia. — In **creusina** *Stich.* (134 e) lying before me from Cuzco (Peru) the submarginal stripe is as fine as a hair and often even obsolete for some distance. — Not rare.

hisbon. **B. hisbon** *Cr.* (= *hisboena* *Hbn.*) (134 g). Much smaller than *creusis*; the median stripe slightly curved like an S, as in *creusis*, but on all the wings the distal stripe is greatly shortened, above and below. South Brazil, rather rare. — In **zonata** *Fldr.* (= *simbla* *Bsd.*, *libna* *Btlr.*) (134 g) all the yellow stripes are considerably widened, particularly in the ♀, and behind the (shortened) outermost stripe of the forewing, which is mostly fusiform, we notice another small yellow spot in the anal angle of the forewing. Mexico to Colombia. Common. — **expleta** *Stich.*, on the contrary, denotes specimens in which the yellow spots in the distal part of the wings have disappeared altogether or to some traces of them. Described from Honduras.

capreolus. **B. capreolus** *Stich.* (134 g) approximates the preceding species, but the fusiform distal spots are coherent with the yellow median band by means of a broad pedicle. Colombia.

*) Genera Insectorum, Riodinidae p. 227.

B. melanis Hbn. (134 g). In typical specimens the median band is still narrower than on our figure; *melanis*, instead of it, however, also the hindwing exhibits yet a shortened and often darkened piece of the distal stripe, as for instance in specimens from Rio de Janeiro. The figured specimen originates from Petropolis; here only faint shades of the distal stripe are still noticeable. In specimens from São Paulo the distal stripe has entirely disappeared above, and the basal stripe is in no case visible above; beneath, however, all the stripes are to be seen, though they are often narrow.

B. johannae E. Sh. (134 g). I cannot tell for sure whether this species is justified to be placed into *johannae*, this genus; the wing-contour and the structure of the body deviate from the other *Baeotis*. We see here only yet a pale-yellow median band running broadly through the dull blackish wing. North Brazil. — In a ♀ from Ceara the median band is extremely narrow, but there are traces of a submarginal stripe to be seen; I denominate this form **cearaica** *form. nov.* (134 g). — We must remark yet that the width of the *cearaica*, median band, as well as its shape vary greatly according to the district. In the form **truncata** Stich. from *truncata*, Minos Geraes it is even obsolete for some distances. — Not common.

B. barce Hew., which is not before me, seems to me to be only an aberrative form of a *Baeotis barce*, approximating *johannae*. Here the yellow median band is present only on the hindwings, whereas on the forewings it is obsolete except a tiny median spot and a faint beginning at the inner margin. It was described from Mexico, but I did not find anything similar in the copious collections from Mexico, which I examined.

B. barissus Hew. which has been placed here, but which probably is more correctly taken to the *barissus*, following genus, is a small dark-brown butterfly with 6 parallel, yellow transverse stripes; it pretty exactly resembles the ♀ of *Argyrogramma trochilia*, as we figure it t 135 d, but the light dots in the dark distal margin are absent. Ecuador is stated as its patria. The species is considerably smaller than *A. trochilia*.

59. Genus: **Argyrogramma** Stich.

This genus already approximates the *Charis*-group to which its species had formerly been placed. They all are small, extremely delicate butterflies, the structure of which is allied to that of the *Caria*, and of the *Phaenochiton* which are likewise mostly dealt with as *Charis*. At the palpi the first joint is conspicuous for its great length being uncommon in *Erycinidae*. In the veins we have to mention the relatively long cell of the hindwing, being only little shorter than that of the forewing. From the subsequent Anteros it deviates by the shape of the hindwings. STICHEL places 12 distinct species here, which are allied to the genera dealt with last in the habitus and the colouring.

A. trochilia Ww. (135 d). The ♂ is of a brilliant sky-blue with black transverse stripes and a dark *trochilia*, distal margin being finely filled up by orange. The ♀ has 5 yellow stripes on a dark ground and a metallic line often reduced to tiny spots before the border. Under surface of both sexes striped like a zebra. On the Lower Amazon the species is not very rare. — **leptographia** Stich. of which only the ♂ is before me, is *leptographia*, of a very bright sky-blue sapphire-lustre, with a broader orange filling in the border and a blackish dotted instead of striped under surface; taken by FASSL near Muzo in Colombia.

A. saphirina Stgr. (135 d) is considerably larger; the ♂ reminds us of *Voltinia theata*-♂ (126 d), but it *saphirina*, has a lighter blue lustre, and an under surface resembling exactly the upper surface of its ♀; in the latter both surfaces are almost alike, blackish brown with broad yellow stripes and a metallic line before the border of the forewing. Before me only from Colombia, but it is also mentioned from Peru and Bolivia. — In *subota* *subota*, Hew. from Ecuador the distal bands being interrupted in *saphirina* are complete.

A. glaucopis Bat. (142 g). From Teffé on the Amazon. Here the ♂ has behind the middle of the fore- *glaucopis*, wing a broad smalt-like transverse stripe, similar spots in the cell, and one in the distal part of the forewing; at the base of the forewing and at the inner margin of the hindwing dark red oblique spots. Before the border a blue metallic line. The under surface with numerous black chequered spots and an interrupted metallic line before the border. The ♀ which is not yet described and which we figure, resembles somewhat a small *saphirina*-♀; the transverse stripes of the forewing are complete, those of the hindwing interrupted; the yellow is darker, more ochreous, at the border of the hindwing even bright orange. Under surface with black spots which, however, are arranged to stripes.

A. barine Stgr. (135 c, as *barsine*). The ♂ has behind the middle of the forewing a smalt-like spot *barine*, placed on the inner margin, and dark small spots in the disc of both wings; the ♀ is lighter, yellowish-grey, with darker macular bands and a blackish distal marginal part of the forewing with a blue spot before the middle of the border. From the Rio San Juan in West Colombia.

A. amalfreda Stgr. (135 c). Here the whole hindwing, except the border, and the proximal half of *amalfreda*, the forewing are red with small fine black spots. In the black distal half of the forewing is a smalt-like spot; before the border a metallic line. Pebas. The ♀ is unknown to me. — **nurtia** Stich. (142 g) entirely *nurtia*, resembles the preceding, but it is larger; above the blue spot of the forewing is yet another blue, small spot; the border of the hindwing broader black; Bolivia, Peru. — In **physis** Stich. (137 f, as *rhesa*), on the contrary, *physis*.

- the blue spot is much smaller than in *amalfreda*; Colombia. — *physis* exactly reproduces the appearance of *Lemonias rhesa* Hew., but the latter has a broader black apical part of the forewing and, before the border, a silvery line. — In *phyton* Stich. from the Amazon the blue spot is oblong, larger than in *physis*, smaller than in *nurtia*, and the antemarginal lines of the hindwings are broken up to small streaks.
- occidentalis*. **A. occidentalis** G. and S. (= *juanita* Stgr.) (135 c). As large as *amalfreda*, but the inner part of the wings more miniate than vermillion, more dotted in black, and in the distal part no blue spot. According to STICHEL, the ♀ resembles *A. venilia* Bates. Colombia. — *placibilis* Stich. from Peru has a less intensely darkened distal part of the wings, so that here the black markings are more distinctly prominent.
- venilia*. **A. venilia** Bat., from the Lower Amazon, is somewhat lighter yellow, otherwise similar to **crocea** G. and S. (135 c) from Central America, but just as densely and coarsely spotted. Both the forms are larger than *occidentalis*, with broader wings, and the darkened margin is narrower. Not common.
- stilbe*. **A. stilbe** Godt. (= *perone* Ww.) (135 c). Here the distal part of the wings is no more darkened at all, the dull ochreous-yellow upper surface exhibiting dark panther-like markings. Brazil.
- holosticta*. **A. holosticta** G. and S. (135 c), from Central America to Peru, is almost exactly like *stilbe*, but light lemon-coloured. Mexican specimens have smaller and more sparse dots.
- sulphurea*. **A. sulphurea** Fldr. from Mexico is just as bright light yellow, but the dark spots are larger, particularly at the margins of the wings. — **macularia** Bsd. (= *ochreas* G. and S.) (135 c) from Central America and Colombia has the spots thicker also on the disc of the wings. Not rare.

60. Genus: **Anteros** Hbn.

The species of this genus are immediately recognizable by the under surface in which small, brown or black-bordered spots with metallic centres stand on the light yellow ground. The upper surface is mostly black with a yellowish central spot. Morphologically, the species are distinguished by two characteristics: by a beard consisting of long cilia at the anal angle of the hindwing and by dense, brightly coloured flocks of hair at the legs. Most of the species are not common; they mostly rest on the under surface of leaves with their wings spread out, but sometimes they clap their wings together above the back. The flight is somewhat Lycaenid-like. Of *renaldus* forming already a transition to the *Ourocnemis* I saw the ♂♂ sometimes on open spaces in the woods, playing with each other and dashing up and down in enormous oscillations so rapidly that it was quite impossible to recognize them during their flight; it is the same peculiar habit I also noticed in some Indian butterflies of other families, in the Lycaenid *Bindahara phocides* and the Hesperid *Tagiades atticus*.

- chrysoprastus*. **A. chrysoprastus** Hew. (133 f). Under surface very pale yellow, the small spots dispersed and tiny, without a true brown halo. Upper surface blackish brown, the hindwings margined in bone-yellow. From Guatemala to Bolivia. The ♂♂ of the southern habitats mostly have in the forewing a tiny light median spot, specimens from Panama, the Chiriqui and Paramba are above without any small white spots at all. = **roratus** G. and S. (133 f); specimens from Bolivia (Rio Songo) form the intermediary, i. e. there is a faint trace of the median spot of the upper surface. Not rare.
- roratus*. **A. roratus** G. and S. (133 f) entirely resembles the preceding and may be of the same species; the median spot on the upper surface of the forewing more distinct; beneath a dark beam above the cell-end of the forewing, and in the ♀ intense, dark spots with metallic centres above the anal angle of the forewing which are smaller or absent in ab. **cumulatus** Stich. (133 f). Chiefly at home in Colombia, where it is rather common; rarer in Central America and Ecuador.
- allectus*. **A. allectus** Ww. (133 f) Forewing above with a very large yellow spot occupying in the ♀ the whole centre of the wing; beneath, both wings with a very large dark median cloud. Lower Amazon. May be only a collateral-form of the preceding species.
- otho*. **A. otho** Ww. (133 f). Forewing above with a very large yellow spot occupying in the ♀ the whole centre of the wing; beneath, both wings with a very large dark median cloud. Lower Amazon. May be only a collateral-form of the preceding species.
- formosus*. **A. formosus** Cr. (= *croesus* F., *valens* F.) (133 f). Somewhat larger than the preceding, but the under surface densely covered with spots of a red-brown margin and a golden-centre. — The form **micon** Stich. (133 f, g) has beneath less, **lectabilis** Stich. (133 g) more brown spots; the former occurs more in the north, the latter in the south of the range. From the northern coast of South America to South Brazil and Peru, mostly not rare, but very local. *stramentarius* Stich. from la Paz in Bolivia, *maculosus* Stich. from Panama and *theleia* Stich. are transitions or insignificant deviations. — **cruentatus** Stich., according to a damaged and, as it seems, much flown specimen, is not before me and seems to me to be only a more sparsely spotted example of this species; from Colombia.
- acheus*. **A. acheus** Stoll (= *ampyx* Drc., *troas* Stich.) (133 g). Considerably larger than the preceding; under surface variable, but on the whole rather densely spotted, the spots arranged similarly as in *formosus*. In

typical specimens the forewing has a tiny central spot; in **kupris** *Hew.* (133 g) being mostly still larger a large *kupris*, rhombic spot stands in the centre of the forewing, above, behind or below which may be yet accessory small spots. *aureocultus* *Stich.* is the name for Bolivians being beneath very much spotted. From the northern coast of South America to Bolivia and South Brazil; not very rare.

A. bracteata *Hew.* (133 g). Under surface like that of the preceding species, but the upper surface *bracteata*, unspotted, black, of a blue lustre. Amazon to Bolivia; apparently rare.

A. carausius *Ww.* (= medusa *Drc.*) (133 h). In this species the dark marking of the under surface *carausius*, has increased so much that it has removed the light yellow colour except some traces before the apex. Upper surface dark brown with 2 vitreous spots. Mexico and Central America. — In the smaller form **principalis** *Hpffr.* (= *carus* *Godm.*) (133 h) lying before me only from Bolivia, the under surface of the hindwings is marked more indefinitely and the forewings exhibit yet a third, very tiny spot. — In FELDERS collection in Tring there is a transition without the patria being stated. Apparently rather rare.

A. renaldus *Stoll* (133 h). Tiny vitreous spots, mostly only 1, comma-shaped, at the cell-end. Wings *renaldus*, above deep dark blue except at the black apical part. Under surface earthy-brown with faintly lighter and darker shades. The name *indigator* *Stich.* denotes specimens in which the blue of the upper surface is narrowed. Central America to South Brazil. — **notius** *Stich.* (133 h) are South Brazilians with a more indefinitely marked under surface. — The butterflies are not rare, but very local and difficult to capture, as they fly rapidly. *notius*.

61. Genus: **Ourocnemis** *Bak.*

Approximating the preceding genus, but immediately recognizable by the shape of the wings. The forewing more pointed, with a strongly bent costa, a more pointed apex and a slightly curved border. The hindwing projects not only in the anal part, but also in a faint tooth at the places where the lower median veins terminate. The palpi are long, with thick, club-shaped, projecting ends, the legs less long haired. The species are apparently extremely rare.

O. bouletti *le Cerf* (133 h). Under surface rather similar to that of *A. carausius*; upper surface blackish, *bouletti*, the wings in the disc with a dull blue gloss, without vitreous spots, hindwings at the anal part of the distal margin faintly tinged in a rusty colour. The type I figure and which the Paris Museum had lent me, is denoted by „Matto-Grosso“; FASSL sent another specimen from the Rio Songo.

O. axiochus *Hew.* (133 h). The type has a dark, less variegated under surface, the booth at the end *axiochus*, of the lower median vein is more obtuse, the blue lustre of the upper surface duller, more diffuse, the border of the hindwing not rusty red in its anal part. „Brazil“; before me from Cuyaba (Coll. BANG-HAAS).

62. Genus: **Sarota** *Ww.*

Differing from the preceding genera by the less hairy legs (which, in *Anteros*, look like hairy tassels) and by the hindwings of some species terminating, like in *Helicopsis*, into a series of divergent tail-points. The butterflies are brown, above without metallic colours, beneath, however, with a variegated marking decorated with metallic fillets, which somewhat reminds us of that of the Indian *Hypochrysops*. In contrast with the preceding genus the species of which number among the greatest rarities, the *Sarota* are not rare where they occur.

S. chrysus *Cr.* (133 h, i.). Blackish brown, hindwings lighter; ♀ above lighter with many large spots *chrysus*, of the forewing, ♂ darker with less and small spots of the upper surface. Typical *chrysus* have light diffuse spots in the variegated marking of the under surface, of which the one before the middle of the distal margin is particularly large, rectangular, transverse. — In ab. **dematria** *Ww.* (133 i) the spots of the under surface *dematria*, are reduced, particularly the large, light, transverse spot is not prominent. — ab. **polypoecila** *Stich.* are very *polypoecila*, light ♀♀ with remarkably many light spots. — ab. **neglecta** *Stich.*, on the contrary, has none or scarcely *neglecta*, any light spots of the upper surface. — From Mexico, where the species flies near Misantla in very large dark specimens, through Central America and Colombia to the Amazon; in many districts common.

S. acanthoides *H.-Schäff.* Recognizable by sabre-shaped, feathered small tails being placed at all the *acanthoides*, terminations of veins at the border of the hindwing. Typical specimens from Guiana and the Lower Amazon have shorter tails, those from the Upper Amazon (Pebas) longer tails (= **spicata** *Stgr.* 133 i). The latter have *spicata*, also a darker under surface and more distinct black spots between the metallic stripes of it. — Rare.

S. acantus *Cr.* (= *acanthus* *F.*) (133 i). This species greatly resembles *gyas*; both are above blackish- *acantus*, brown, beneath with varyingly red and smaltly-lustrous transverse stripes. *acantus*, however, differs from *gyas* by having black forelegs, while *gyas* has reddish-yellow ones. Guiana to Bolivia; not rare.

- gyas*. **S. gyas** Cr. (133 i). Mostly smaller than the preceding species; besides recognizable by the yellowish-red forelegs which are black in *acantus*. The marking beneath similar as in *acantus*; some ♀♀, however, have above a yellow border of the hindwing (= *lasciva* Stich.). Central America to Brazil.
- myrtea*. **S. myrtea** G. and S. replaces *gyas* to the north of Nicaragua, as far as Mexico, but differs by the black forelegs. Beneath the second submarginal metallic band, which in *acantus* runs almost as far as the costa, ends already at the median. Rarer.
- gamelia*. **S. gamelia** G. and S. (133 i) has like *gyas* yellowish-red forelegs, but the forewings have here beneath oblong submarginal spots which are absent in *gyas* and *myrtea*. Otherwise the species greatly resembles the latter, but *myrtea* has black forelegs like *acantus*. Common, Central America.
- psaros*. **S. psaros** G. and S. Similar to the preceding, at the border of the hindwing there are small tips at the ends of the veins. The under surface is lighter, particularly in the disc of the wings, where it is almost whitish, the markings and spottings of the allied species are here scarcely indicated. This species was based upon a single ♀ from Guatemala. — **psaronius** Stich., based upon 2 South Brazilian ♀♀, is beneath almost white, in some places dusted in grey, and it has a red border of the wings, being also larger than *psaros* from Guatemala.

63. Genus: **Charis** Hbn.

This genus comprises a great number of tiny butterflies, all of which exhibit metallic lines before the border of the wings, which is pointed at the apex, the distal line running closely in front of the border of the wings, the second line 1 to 2 mm before it. The upper surface is rather unicolorously black or dark brown. The bodies are mostly very delicate. The butterflies, in contrast with most of the *Erycinidae*, are nearly all very common, sitting with their wings extended or spread out high (as if pinned) on umbels or compositae, mostly in their centres, which they do not like to leave. They then rise in a somewhat buzzing flight, usually only to the next blossom where they settle down again. Like many *Erycinidae*, they seem not to fly much spontaneously.

- anius*. **Ch. anius** Cr. (= *anius*, *avius* auct., *eleodora* Godt.) (134 a). The many hundreds of specimens lying before me of this common species vary scarcely; they are recognizable by the under surface of the ♂♂ with a magnificent deep blue reflection. The ♀ has not so distinctly white fringes of the hindwings and somewhat more pointed forewings than our figure which was depicted according to a very much flown specimen and retouched by a mistake in an exaggerated way by the artist. Also the speckling of the fringes of the forewings is always present, but often scarcely noticeable. From Central America to Brazil, Ecuador and Bolivia. — We may add here **calagutis** Hew. without the patria being exactly stated, exhibiting above only 1 silvery line, the under surface being dull dark grey instead of metallic blackish blue.
- cleonus*. **Ch. cleonus** Stoll (= *timaea* Dbl.) (134 a). Similar to *anius*, but recognizable by the white fringes of the hindwing and by the under surface of the ♂ being about like the upper surface, black with 2 parallel, blue-metallic lines in front of the border and white fringes of the hindwing. The ♀ has on both surfaces between the silvery lines a red-brown, dotted marginal band. Guiana to Brazil and Bolivia. Common. — **caryatis** Hew. (= *cleonus* Godt. nec Stoll) has a black under surface, with but 1 silvery line, being on the forewing widened like a band; from the Amazon.
- gynea*. **Ch. gynea** Godt. Similar to the preceding, but much narrower fringes being mostly speckled on both wings, and differing by the ♂ being coloured like the ♀, i. e. dusted with red-brown. The metallic lines are above before the border quite thin, often only the distal line is preserved here, and quite faintly. South Brazil, preferably sitting on yellow compositae so persistently that one may take it away with the poison-glass, if done cautiously. — **zama** Bat. (134 a) from the Amazon is above more rusty brown, the leaden lines more intense, the spaces between the veins parted by dark; the under surface reddish-fawn-coloured. — **candiope** Dre. is above more greyish-brown, beneath red-brown, on the whole larger; from Colombia. — Common.
- argyrea*. **Ch. argyrea** Bat. resembles the preceding, but above it is still darker than *candiope*, with indistinct dark dots above. The fringes are not white-speckled, there are on those of the forewings at most few white dots; the space between the silvery lines is not red-brown, but dark brown. From Teffé; perhaps only a form of *zama*. — **aerigera** Stich. seems to approximate this form, but it is beneath dull yellowish-grey and the proximal silvery line is cut through by the veins. South Brazil. Unknown to me.
- jessa*. **Ch. jessa** Bsd. is a species which is said to originate from „Brazil“, unknown to me; there does not exist any description of it; STICHEL places it near *hermodora*; according to the figure it might belong to one of the species already quoted.
- hermodora*. **Ch. hermodora** Fldr. (134 b) is a small species from Colombia, Venezuela and Panama. It greatly approximates *anius*, but the under surface is here not of a lustrous blue, but like the upper surface, except that there is beneath only 1 silvery line. Not rare.
- thedora*. **Ch. thedora** Fldr. (134 d). Above similar as *anius*, but the proximal metallic line on the hindwing is expanded to a band being broader in northern specimens, narrow in southern ones. Brazil, Bolivia and Peru.

— *stilbos* *Stich.* (134 d) is the representative of the species from Colombia, in which the proximal metallic *stilbos*, line is broader also on the forewing and, on the hindwing, so broad that it is partly confluent with the distal one. — On compositae common.

Ch. panurga *Stich.* has an under surface similar to that of *anius*, but it is considerably larger and *panurga*, has only 1 silvery line and white fringes; the upper surface is blackish-grey with a blue lustre, similar to *hermodora*. I do not find the patria being stated.

Ch. lypera *Bat.*, from the Upper Amazon, has already the size of the following form and also its *lypera*, dark brown upper surface; the black discal spots are partly confluent to a median line, the reddish distal marginal band is defined by a silvery line, traversed by a row of dots. Upper Amazon; very closely allied to *chaonitis* (134 d).

Ch. chaonitis *Hew.* (134 d). Very similar to the preceding species, but instead of the black line formed *chaonitis*, of fine streaks, a sinuous nebulous band runs through the centre of the wings. From Guiana to Bolivia.

Ch. chelonis *Hew.* stands in the middle between *chaonitis* and *epijessa*. The distal silvery line is ab- *chelonis*, sent altogether or it is exhibited only in single, small silvery scales, the proximal line being also duller. Also the colouring forms the intermediary between that of *chaonitis* and *epijessa*, being in specimens from the lowlands (Rio de Janeiro) yet rather violettish-brown, in those from the highlands more dark brown. Apparently very rare; specimens like those figured by HEWITSON are not known to me at all, but only such forming transitions to

Ch. epijessa *Prittw.* (= *calicene* *Hew.*, *calinice* *Stich.*) (134 b, as *chelonis*) from the summit of the *epijessa*, Corcovado and from the Organ Mountains; here, however, the ground-colour turns entirely fox-coloured, the silvery lines are entirely extinct beneath, while above they are so only here and there, the black dots in the marginal band are finer, but owing to the lighter ground-colour more prominent than in typical *chelonis*. Moreover both forms, exhibiting probably differences of the habitats (? elevation), are very closely allied to each other, but the ♂ of *chelonis* has broader forewings. — As a smaller, darker form from the south (Espiritu Santo) **charis** *Hew.* may be considered, in which the proximal silvery line is sometimes fairly well *charis*, preserved, but sometimes also hardly recognizable. This is probably also the place where **azora** *Godt.* belongs, *azora*, which is unknown to me, although I collected numerous *Charis* to be inserted here in its patria South Brazil; it may be only a subrace of *Charis charis*.

Ch. velutina *G. and S.* (134 c) has the shape of *chelonis*, but a darker, almost black colouring which, *velutina*, in the ♂, shows beneath a bluish tinge. Recognizable by the proximal metallic line being irregular, several times interrupted. Central America to Colombia. — **iris** *Stgr.* belongs hereto, according to the description, *iris*, though nothing is mentioned regarding the course of the proximal silvery line; it is denoted to be „the most closely allied to *cleonus* or *zama*“. *iris* is unknown to me; from the Chiriqui.

Ch. cadytis *Hew.* (134 c, as *cadytes*). Easily recognizable by the proximal silvery line being shaded *cadytis*, orange-yellow above at the costa. South Brazil, Paraguay. — **acroxantha** *Stich.* (134 d), likewise from South *acroxantha*, Brazil, is said to have „transformed the red submarginal stripe of the forewing to an ochreous-yellow, oblong subapical spot“; but as the author declares not to be able himself to tell whether our figure represents one or the other form, the name is probably better to be abolished.

The following species, mostly from North America, deviate from those enumerated so far in several details (genus *Calephelis* *Gr.* and *Rob.*); they have somewhat more obtuse forewings, but nearly always distinctly the silvery lines of the *Charis*-species.

Ch. borealis *Gr. and Rob.* (134 c). Above dark brown with very indistinct silvery lines, the proximal *borealis*, one being irregular and often interrupted. Under surface reddish-yellow, the discal, dark dots arranged in 3 or 4 arcuate rows. United States, more to the east and rare.

Ch. nemesis *Edw.* is presumably only the western representative of the preceding, from more arid *nemesis*, districts of Arizona and South California, considerably smaller (only as large as *caeneus*); across the middle of the wings above runs a dark, angular shade, more distinct than in *borealis*.

Ch. australis *Edw.* (= *guadeloupe* *Streck.*) (134 b) is likewise very closely allied to the preceding, but *australis*, it has darker markings than *nemesis*; the brown median band is more prominent, the wings are without the white dots of the fringes exhibited in *nemesis*. Mexico, Texas. — **costaricola** *Stgr.* exactly corresponds with *australis*, as it flies in some places of Mexico (Misantla). — **fulmen** *Stich.*, like the preceding from Costa Rica, *fulmen*, is unknown to me; it is said to have the form of *iris*, but a black band across the middle of the wings and speckled fringes. Under surface light rusty brown.

Ch. caeneus *L.* (= *pumila* *Bsd.*, *virginiensis* *Gray*) (134 c). The name is assigned to a somewhat du- *caeneus*, bious species of LINNÉ, as which, however, the butterfly belonging here was generally considered, although the name was several times misspelled as *caenius*, *cenea*, *ceneus*, *cerea* etc. Fresh specimens exhibit the brown, black-spotted upper surface finely strewn with isolated blue, somewhat metallic, small silvery scales being

united to groups at some of the small black spots and forming beneath (sometimes also above) two lines parallel to the border. The small silvery scales are much too fine to be reproduced on a figure. Not rare in Florida; to the north as far as Virginia, to the south as far as Texas. — *argyrodines* *Bat.* (134 b) is the South American form, darker, sometimes above almost black, the ♀♀ also larger; the upper surface dotted more distinctly, the silvery lines of the under surface more prominent, the proximal one running also somewhat differently. Between the ranges of the two forms there occur intermediate forms, as for instance *laverna* *G.* and *S.* from Mexico and Central America, with a somewhat more pointed apex of the forewing, and *nilus* *Fldr.*, from Venezuela, with a more deeply coloured upper surface, a grey macular marking and dull-lustrous leaden lines. — The forms can neither be strictly separated from each other nor be arranged according to patriae. The animals rest spread out, as if pinned, on yellow compositae resembling our *Leontodon*, close at the soil, and can be taken off with the poison-glass. On being chased away, they fly beneath the nearest leaves of the bush and soon return to their flower again. Very common. — Regarding a species unknown to me and not recognizable according to the description, *azora* *Godt.*, which is said to originate from South Brazil, though I did not discover it, I doubt whether it is allied hereto as the southernmost form, or — as STICHEL wants — to the South Brazilian *epijessa*, resp. *calicene*, where we have mentioned it. — *xanthosa* *Stich.* (142 g) is certainly allied hereto, a bright red-yellow form, the silvery scales are presumably extinct; type from the Coll. SCHENCK VON SCHWEINSBERG at Darmstadt, now in the Berlin Museum, presumably from South Brazil.

aphanis. **Ch. aphanis** *Stich.* (142 g) from Uruguay is larger and of a grey ground-colour.

ocellata. **Ch. ocellata** *Hew.* (134 b). I was not able to find the type in HEWITSONS collection. It seems to be an aberration of a *Charis*, in which the silvery lines are absent and the red-brown, black-dotted band lying otherwise between them has turned a chain of eye-spots in which single eye-spots are especially distinctly prominent. It is scarcely a *Symmachia*, as HEWITSON supposed; much rather an unfringed *Ch. zama*. From Venezuela.

64. Genus: **Crocozona** *Fldr.*

The structure of the body, the very delicate, outside broad wings with a long-stretched apex and a very much rounded border, the metallic lines or small scales ally this genus immediately to the *chaonitis*-group of the preceding genus. The inner margin of the forewings is almost as long as the costal margin, the hindwings are very broad. The colouring is black with scarlet or orange-red bands which are partly bordered in metallic lines. Only 3 or 4 species are known occurring in the northern part of South America, where they are not rare; FASSL found them early in the morning drinking from the dew on the leaves.

caecias. **C. caecias** *Hew.* (134 d, e). Both the wings are traversed by a scarlet transverse stripe running rather parallel to the border. Beneath it is in the ♂ greatly widened and tapering at both ends. Bolivia, Peru and on the Amazon; near Pozuzo (Huanuco) and on the Chanchamayo at an elevation of up to 1000 m not rare.

arcuata. — **arcuata** *Godm.* (134 e) deviates by the red stripe of the forewing running more inwardly towards the costa. Colombia, not rare. The red stripe varies, moreover, according to the finding-places not inconsiderably in width, particularly beneath.

pheretima. **C. pheretima** *Fldr.* (= *caciparis* *Hew.*) (134 e). The red stripe of the forewing lies obliquely, that of the hindwing is absent. On the under surface the whole disc of the forewing is red as far as to the base. In Colombia, in some parts not rare; taken by FASSL in December in the Canon del Gallo, at an elevation of 1600 m, and near Muzo (1500 m).

fasciata. **C. fasciata** *Hpfgr.* (= *clusia* *Hew.*) (134 e). Larger than the preceding; the spot of the forewing is shortened to a more transverse oblique spot. Peru and Bolivia; La Merced in August and September.

65. Genus: **Astraeodes** *Schatz.*

A comparatively large butterfly deviating entirely from all the other *Erycinidae* in its exterior, but distributed over a great part of South America, forms this genus. The veins do not differ essentially from those of *Baetis* and the other allied groups. The body is delicately and gracefully built, the wings are very broad, with a metallic line in front of the border. Nothing has become known to me with respect to its habits.

areuta. **A. areuta** *Ww.* (128 i). Orange-yellow, with 3 dark transverse stripes, a golden line before the border and a row of dots in front of this. From East Brazil through the Amazon Valley to Peru and Bolivia. The variation of the different finding-places refers to the more lemon-coloured or pale ground-colour, to single dark spots before the border of the hindwing beneath, and the thickness of the transverse stripes. Everywhere rare.

66. Genus: **Amblygonia** Fldr.

After eliminating the species placed here by FELDER, the name of the genus remains for the following species. A tiny, square-built butterfly with a robust body and broad wings traversed by a yellow band. Silvery lines are absent; remarkable are 4 larger spots of the wings occurring in the ♀ — a form of the sexual dimorphism being otherwise not common.

A. amarynthina Fldr. (= monogramma Bat., barzanes Hew., ♀ = quatrilotata Btlr.) (132 h). A small species. Blackish brown with a small orange-yellow, above often darkened median band, the much rarer with one light yellowish-white dot in front of the middle of the distal margin on each wing. The ♂♂ are not rare in almost the whole of South America, from Argentina to Colombia. The band varies considerably in width and intensity of colouring, but it is in the ♂ beneath always broader and brighter than above.

67. Genus: **Amarynthis** Hbn.

This genus has likewise only one, very singularly coloured species. Larger than the preceding species, less robustly built, the wings very delicate; the veins deviate from those of the *Amblygonia* only by the 3rd subcostal vein not rising immediately before the cell-end, but immediately behind it. The species forming this genus is very widely distributed.

A. meneria Cr. (132 f). Black with a narrow red transverse band and sparse light, small dots: in the cell of the forewing a red cuneiform streak, behind it a small red spot. — In **superior** form. nov. (132 g) flying near Humayta and lying before me in great numbers, the red band, particularly beneath, is more than twice as broad and the dots are of a bright white, larger and increased; the form itself is very large. — In contrast with it, ab. **maecenas** F. (132 g) is without any small white dots. A form being especially in the female sex extremely broad-banded and rather small originates from Nouveau-Chantier in French Guianais **coccitincta** form. nov. (132 g), but already in Cayenne there occur again narrow-banded specimens. This character is local, but not temporal, for I possess homogeneous specimens from April, October, December and February. — **stenogramma** Stich. (132 g) contrasts with *coccitincta* by the red band being here as thin as a thread, even extinct in some places; from Ecuador, where, however, there occur also specimens hardly distinguishable from Peruvians. — **micalia** Cr. (132 f) is the common form living in almost the whole northern part of South America, with a distinct, unabridged, but moderately broad band, in which there is in the cell-end a small red spot isolated from the basal streak, which is confluent with the latter in ab. **conflata** Stich. *meneria* is not so common as we might be induced to believe according to the numerous specimens in the collections (before me are about 300); but it is one of the most conspicuous butterflies, being equally keenly collected by European and native collectors. — I call the reader's attention to a strange coincidence: at the same place ((Humayta on the Amazon), where *A. meneria* exhibits a broad, coloured band and a conspicuously copious white dotting, the same symptom occurs also in another, but very distantly allied *Erycinidae* (*Riodina lysippus* L.) *).

68. Genus: **Exoplisia** G. and S.

This genus was formerly united with the preceding to which it is very closely allied, but its members have somewhat shorter palpi. Certainly the total appearance greatly deviates from that of the *Amarynthis* by the entirely different colouring, but the anatomical structure makes it doubtful whether *Exoplisia* is to be separated from *Amarynthis*. From the following *Nelone*, *Exoplisia* is separated by the finer clubs of the antennae, the appressed palpi, the shape of the wings, particularly the stretched costa of the forewing, the fringes at the anal part of the hindwing being prolonged to a regular beard. Only one species.

E. hypochalybe Fldr. (= praxitheia Bsd.) (132 g). Above dark brown, beneath of a lustrous light blue, with black veins; on both surfaces numerous straight black transverse stripes. Reported from Central America to Peru. — **muscolor** Weeks (132 h) differs scarcely above, beneath, however, the distal transverse stripe running parallel to the border of the forewing is absent. Bolivia. Not rare.

69. Genus: **Nelone** Bsd.

Distinguished from the *Exoplisia* by the projecting palpi, the more strongly clubbed antennae, the quite different shape of the forewings exhibiting an arched distal margin, a curved border, a rounded anal angle and a longer proximal margin, and by the absence of a regular beard at the border of the hindwing, where only longer fringes are formed; the marking is quite different, the veins exhibit metallic rays before their termination, the fringes are speckled. As the species are not congeneric with *hypochalybe*, this being,

*) This symptom which has presumably nothing to do with mimicry, is denoted in the zoology as a local character of variation.

however, the type of *Nelone* to which they are transferred in STICHELS catalogue, a new name for the genus would be necessary, if *Nelone* would give way to the (dispensable) *Exoplisia*.

cadmeis. **N. cadmeis** Hew. (132 h). Above sooty brownish-grey, more darkly clouded, beneath of a steel-blue reflection, on both surfaces with black transverse stripes, with a row of dots in front of the border and, on the forewings, speckled, on the hindwings, white fringes. A series of comma-like streaks in front of the distal margin are distinct particularly on the hindwing. Panama to Peru and South Brazil. Rare.

incoides. **N. incoides** Schs. (= *myrtis* Drc.) (132 h). Scarcely half as large as *cadmeis*; above similar, but the fringes of the hindwing likewise speckled, the streaks in front of the border shorter and noticeable only in a certain exposure to light. Beneath like above, not steel-blue. North Argentina, the adjoining Bolivia and Peru; the figured specimen from Tucuman (North Argentina).

hypochloris. **N. hypochloris** Bat. has the size of *cadmeis*, white fringes being scarcely speckled on the forewings; also the upper surface of it is dark steel-blue, with black markings; beneath like *cadmeis*, without the small black transverse streaks of the latter, but the whole surface of the wings darkened except the distal marginal part being of an intense blue lustre.

70. Genus: **Callistium** Stich.

In the structure of the body it approximates *Amarynthia*, but the shape of the wings is quite different. Undoubtedly allied to *Lasaia* from which it forms the transition to *Charis* as which the only species was originally described. Head uncommonly stout with protruding, furry eyes. The veins do not exhibit any deviations. In its exterior similar to the preceding genus. Only 1 species.

cleadas. **C. cleadas** Hew. (135 i) resembles *N. cadmeis* so much that STAUDINGER took it to be the ♀ of it; but the ♂ is beneath not blue, but shows the same colouring and marking as above. The transverse streaks are thicker than in *N. cadmeis* and differently arranged. On the figure (according to a specimen from Onoribo) we see very distinct white costal spots which, however, are absent in specimens from other districts. Guiana, Amazon. Rare.

71. Genus: **Lasaia** Bat.

Of the shape of *N. cadmeis*, but the lustrous blue colouring is exhibited here on the upper surface, while the under surface is marbled brown and grey; ♀ above greyish-brown. Head and thorax are robust, the abdomen short and small, the antennae long, scarcely thickened at the ends, the wings slightly dentate, particularly the hindwings. Costa of the forewing somewhat curved. The butterflies fly in day-time on flowers, where they sit with their wings spread out horizontally, and they come to wet places on the road; the blue colour glistens brightly in the sun, just like the *Tharops* in the company of which the *Lasaia* are often found. Like the *Charis*, they belong to the more common species. As they sit very tightly on the flowers, they are easy to capture as soon as they are drinking.

meris. **L. meris** Cr. (135 g). Recognizable by a white spot at the middle of the costa on the upper surface of the ♂ hindwing, in which there is mostly (not always) a small black dot. The typical, smaller, darker form being brightly coloured beneath inhabits the district from Mexico to the Amazon; the larger form being beneath more unicolorous, **arsis** Stgr. (135 g), goes from there to the south as far as Paraguay, Bolivia and Peru. The ♀♀ are above smoky-grey with a slight greenish tinge. — Not very common.

sula. **L. sula** Stgr. Almost exactly like the preceding, though more sparsely marked in black; the costal area of the hindwings above dull honey-yellow. Mexico to Colombia. The ♀ is not before me.

agesilas. **L. agesilas** Latr. (135 g, h). Above not so very black as the preceding, the small black transverse streaks more united to chains, the costa of the hindwing without a white spot, blackish. The ♀♀ are unicolorously dark grey, on both surfaces very similar to *Call. cleadas* (153 i). South Brazil and Paraguay. —

narses. **narses** Stgr. (135 h), from the Amazon to the north as far as Central America, has a more blue than green ground-colour of the ♂♂ and a black half-band behind the cell. — Common; nor are the ♀♀ drinking from blossoms like the ♂♂ rare. The butterfly figured by us t. 135 i as „*sessilis*“, differing from *narses* only by a greater regularity of the half-band behind the cell of the forewing and a clearer, less black striated discal part of the upper surface of the ♂, is not that species, but merely the Mexican form of *narses* which needs scarcely be denominated specially. Whereas

sessilis. **L. sessilis** Schs. (142 f) which can probably scarcely be separated from *sula*, is smaller, above more obtuse and more violettish-blue, the small black transverse streaks being very regularly arranged. It has a characteristic under surface being dirty fawn-coloured in the ♂, both the wings are traversed by a faintly iridescent, mother-of-pearl white band. Mexico, near Misantla and Guerrero common.

moeros. **L. moeros** Stgr. (= *rosamonda* Weeks) (135 h, as *pura*). The species is larger and of a brighter bluish-green reflection than the preceding, the black streaks finer, regularly united to rows, the under surface purer and more one-coloured, the distal part without any black speckles. Peru. — **kennethi** Weeks (135 i) from

Bolivia to South Peru has the wings above traversed by regular lines, particularly the hindwing is very much marked. — **merita** Godm. (135 i) has no more black markings on the hindwing, except a row of dots in front of the border; the under surface is tinged reddish; from Coroico (Bolivia).

L. oileus Godm. (135 h). Only half as large as most of the other species. Above dirty dark-brown, clouded irregularly, speckled in black, before the apical part of the costa 2 very small whitish vitreous spots. Beneath in the costal part of the forewing blackish, otherwise dull bluish-white, with dark speckles. In the (larger) ♀ the ground-colour shows a yellowish-brown hue. Widely distributed, probably at home in the whole tropical South America, but rather rare.

72. Genus: **Amphiselenis** Rôb.

An isolated species which is sufficiently characterized by the shape of the wings. The apex is prolonged in the shape of a sickle, and the middle of the border exhibits an obtuse, lobular tooth. In the exterior the animal greatly resembles certain *Achlyodes* with which it corresponds also in the colouring.

A. chama Stgr. (128 h). Dark-brown, the forewings with indentations at the apex, the inner angle, before and behind the middle of the border; the hindwing with an obtuse tooth; both wings are crossed by dark nebulous lines, the distal one of the ♂ beneath being faintly metallic. The ♀ is above more brownish yellow, beneath yellowish, almost entirely without metallic lines: in the Cauca Valley in Colombia and in Venezuela; but not common.

73. Genus: **Calydna** Dbl.

The essential difference of this genus from most of the other genera of the *Erycinidae* consists in the constancy of its forms, resulting in the specimens of one species, even from very remote habitats, not exhibiting any differences. I consider this persevering adherence to the typical form to be an effect of the great power of flight and a reduced adherence to localities. The *Calydna* are robust animals with strong wings and a power of flight and diffusibility comparable with that of the Hesperids of which the *Calydna* remind us also in their habits. They have, moreover, the habits of the other *Erycinidae*, coming to wet places and blossoms, they have an almost buzzing motion of the wings and a compact shape. The antennae are of medium length with a feeble club, the head is broad with a flat forehead beyond which the palpi do not project, the thorax is in many species, such as *caieta*, stout almost like in night-butterflies and decorated with variegated markings. The wings are often densely dotted and marked with transparent spots, the legs are rather short; in the forewings only the first subcostal vein branches off before the cell-end out of which the 2nd and 3rd rise. — In the hindwing the veins do not exhibit any deviations; frequently, however, the anal part of the hindwing is slightly lobate and the apex of the forewing produced. MENGEL includes 29, STICHEL 24 species in this genus.

C. thersander Stoll (135 i, k). One of the largest species, blackish-brown, marbled in slate-blue, spotted darker, the forewings with small white vitreous dots, the hindwings in the ♂ with a sky-blue, in the ♀ with a slate-blue distal-marginal part. Guiana and Brazil. Not common.

C. charila Hew. (135 l). The ♂ resembles the *thersander*-♀, but the small vitreous spots in the forewing are somewhat larger, and the blue united to festoon-like arcuate lines, particularly in front of the border. The ♀ is quite different, similar to the ♀ of *caieta* (135 l), but in place of the uniform yellow spots of the latter there appear small fenestrae bordered by red-brown and alternating with opaque red-brown spots, between which blue-metallic intermediate spots are embedded. Upper Amazon, as far as into Peru (Pachitea); rare.

C. caieta Hew. (135 l). The wings are densely covered with whitish-yellow (♂) or honey-yellow (♀) spots; beneath like above, the spots slightly larger. Reported from the Upper Amazon; before me are typical specimens of both sexes only from Venezuela (Rio Caura, Suapure). Rare.

C. chaseba Hew. (136 a). On the upper surface the reddish iron-grey ground-colour is crowded with white vitreous dots which turn to streaks in the cell of the forewing. Beneath the hindwings are dusted with a mealy white colour. The ♂ is almost exactly like the figured ♀, but the small spots are a little finer and the forewings somewhat more pointed. Before me are typical specimens only from South Brazil (Rio de Janeiro, Espiritu Santo), but it is described from the Amazon. Rare.

C. punctata Fldr. (136 a, as *punctula*) resembles the preceding species, but it is smaller, the ♂ above jet-black, the ♀ yellowish-brown, the small dots fine like the stings of a needle, the under surface not powdered in white. Ecuador, Peru, Bolivia. The finding-place „Santa Catharina“ is probably due to a confusion with the preceding species. Less rare. It reminds us of *Cremna actoris*.

C. calamisa Hew. (135 l). ♂ black with bands and spots of a magnificently deep-blue lustre, between them white vitreous dots. Under surface dark brown, finely striated and chased, the small vitreous spots here of a mother-of-pearl lustre. ♀ entirely different, on both surfaces like the ♂ beneath, copiously striated; the small vitreous spots are somewhat larger. The ♂ somewhat reminds us of *Cremna meleagris*, just like *Calydna caieta* of *Cremna eucharila*. On the Amazon, from Santarem to Peru.

- lusca*. **C. lusca** Hbn. (135 k). ♂ similar to *charilla*-♂, smaller, the forewings with some larger vitreous spots at the costa, the hindwings angular in the middle of the border. ♀ similar to that of *calamisa*, but the small vitreous spots scarcer and in some places larger, the ground-colour intermixed with red-brown. Colombia to Peru. — **venusta** G. and S. is the northern form going as far as Mexico; here the ♂ is more brightly marked, the fenestrae larger, the black ground-colour more intermixed with lighter bows. ♀ brown, otherwise like the ♂. Rare.
- euthria*. **C. euthria** Ww. (135 k). Quite similar to the preceding, but scarcely more than half as large, much more unsteadily marked, on each wing only 1 larger vitreous spot. Amazon; some more finding-places are doubtful.
- micra*. **C. micra** Bat. approximates the preceding, is velvety brown, irregularly speckled in brown and spotted in black, before the border a number of black, brown-tinged spots are arranged to a band. Numerous vitreous dots, those in cells of the wings larger, as well as some near the apex. Amazon; rare.
- sturnula*. **C. sturnula** Hbn.-G. (135 k). Similar to the preceding, larger, the dark-brown ground-colour exhibits numerous red-brown embeddings, the forewing behind the cell with a larger vitreous spot and several dots as fine as the stings of a needle. Guana to North Brazil. — **hegyas** Fldr. from Central America and Mexico chiefly differs by the small white spots being not so distinctly prominent. — Rare.
- sinuata*. **C. sinuata** Fldr. This species described from Actajac in Mexico is said to be like *hegyas*, but smaller by one third, with a somewhat sickle-shaped apex of the forewing and a dentate border; the hindwings more gnawed out, the colouring above more dark ashy grey, the fringes speckled in a dirty white.
- calyce*. **C. calyce** Hew. (135 k). Differing from the preceding by the basal and distal parts of the hindwings being brownish-yellow in the ♂, more honey-yellow in the ♀, the centre being dark, though decorated with several small vitreous spots. The under surface similar to the upper surface. Amazon; we figure it from Santarem.
- cabira*. **C. cabira** Hew. (135 k). ♂ black, ♀ brown, both recognizable by the two white vitreous spots behind the cell-end being joined to an oblique band. Amazon. Not common.
- cephissa*. **C. cephissa** Hew. This species from the Upper Amazon has on a blackish-brown ground honey-yellow spots in, behind and below the cell-end as well as before the anal angle of the forewing and behind the cell-end of the hindwing. — Before the distal margin a series of fine vitreous dots, as small as the sting of a needle. The under surface somewhat resembles that of *Apodemia erostratus* (141 a) or of certain *Phyciodes*, but it has no brownish-yellow at the base of the wings. From the Upper Amazon.
- maculosa*. **C. maculosa** Bat. Unknown to me; is said to have the shape of *cabira* (135 k), but a less produced apex of the forewing and a less angled border of the hindwing. Above fawn-coloured with many dark square spots in a yellowish-brown corona and many small whitish spots, one of which is in each cell of the wings, below the rising of the first median vein, and a series of 7 or 8 behind the cell. Fringes darker and with lighter brown speckles. Likewise from the Upper Amazon.
- caprina*. **C. caprina** Hew. (136 a). Larger than the preceding, but blackish-brown with a white oblique oval of the forewings, beneath fawn-coloured, with a darker tinge, at the costa of the forewing and the inner margin of the hindwing lighter and striated in black. North Brazil.
- catiena*. **C. catiena** Hew. Similar to the preceding, but the upper surface unicolorously dark brown, except the white oblique oval of the forewing. Beneath dark fawn-coloured, striated dark and with some scattered black dots. Apex of the forewing pointed, border not gnawed out. Brazil.
- carneia*. **C. carneia** Hew. (136 b). Very near to *cabira*, but the white transparent band formed by the double-spot behind the cell-end is angled, as the lower spot extends towards the border. Larger than *cabira*. Beneath at the base of the forewing a reddish-yellow spot. Amazon. Rare. •
- catana*. **C. catana** Hew. (136 b). In the ♂ the two white fenestrae of the forewing are moved apart, so that the black ground-colour passes through between them. On the hindwing appears a small white subbasal band. In the (brown) ♀ the two spots of the forewing as well as the spot near the base of the hindwing are considerably smaller. Venezuela and the adjoining district of the Amazon (Humayta).
- hiria*. **C. hiria** Godt. (= *calitas* Hew.) (136 a). The forewings exhibit only yet a white square spot and above it, below the costa, another dot, the hindwings near the base a bottle-shaped spot. In the ♀ all the spots are smaller and stand on a yellowish-brown speckled ground. Widely distributed. Specimens from Peru (Pachitea) are considerably larger than those from the Amazon or from farther to the north. Rare.
- cea*. **C. cea** Hew. (= ? *zea* Schs.) (136 b). Forewings like in the preceding species; but the hindwings have no white basal band, but in the ♂ a sky-blue distal margin. Before me are only ♂♂ from Bolivia.

74. Genus: **Emesis** F.

Whereas the preceding genus was composed of almost unexceptionally rare butterflies, the *Emesis* consist of almost universally common species. In the Erycinidae, rarity and commonness may very well be connected with their habits, whether they fly in day-time or not. In single *Emesis* there prevails the habit of hiding beneath leaves during day-time, and I have, for instance, often beaten out *Emesis fastidiosa*. *E. mandane*, however, is always found on blossoms and swarms in the hot sun of the forenoon. *E. fatima* mostly rests beneath leaves, but it often comes forth to visit flowers. When, at one occasion, a *fatima* ventured to come out of its hiding-place within sight of me, it was immediately pursued by a *Colaenis julia*-♂ dashing upon it and so unmercifully belaboured with its feet and wings, that its delicate wings were broken and the poor animal at last lay in the dust incapable of flying. On the whole, we may say that the stout *Emesis* (such as *mandane*) are good flyers, the slender ones (such as *fastidiosa*) are bad flyers. The colour of the *Emesis* is mostly brown, with a dark undulate marking, the antennae are long and stretched straight forward by the living animal. The moderately long palpi are so closely appressed to the forehead, that their tips are not to be seen from above. The legs are strong, but not very hairy, the wings entire, with a frequently produced or sickle-shaped apex, in the veins there is no difference from the general type of the Erycinidae. About 50 forms have been distinguished.

E. lucinda. The typical species is the largest of the genus and at the same time one of the largest Erycinidae altogether. — The most common form in the European collections is the South Brazilian *fastidiosa* Mén. (136 d). Above dark-brown, undulated in black; the ♂ has a rusty-yellow apex and a red-yellow under surface, the ♀ a white-spotted apex and a pale-yellow under surface; this under surface is in both sexes richly decorated with brown transverse streaks and chains of bows. — *aurimna* Bsd. (136 d, e) from Central America to Colombia, is above more deeply black with a faint steel-blue lustre. — ab. *albida* ab. nov. (136 e) has in the female a drab upper surface which is almost as vividly marked as the under surface; from Central Brazil (Bahia). — *opaca* Stich. (136 d) exhibits in both sexes the wings very dark and without a distinct brightening at the apex; from the Upper Amazon (Iquitos, Pebas). — *lucinda* Cr. (= *dyn-dima* Cr., *lassus* F.) (136 b, c) exhibits above a blue reflection in the ♂♂ being beneath rusty-red, while the ♀ is brown with an oval white subapical spot; from Guiana and Venezuela. — *spretia* Bat. from Teffé on the Amazon is in both sexes slate-grey, at the apex of the forewing is an indistinctly defined red-brown spot which in the ♀ replaces the otherwise mostly white subapical spot. — *saturata* G. and S., described according to 1 specimen from South Mexico, is above bright and intensely brown, in the basal part are some indistinct transverse lines, in front of the border a broad, lighter line; beneath rusty-red, ruled with black lines, with a similar submarginal band. The palpi are rusty-red. They are recognizable by the colour of the upper surface. — *liodes* G. and S. is smaller, the ♂ above quite unicolorously dark brown with a scarcely noticeable transverse marking, the ♀ with a dull bone-yellow subapical spot of quite the same shape as in the ♀ of *lucinda* (136 c). — *eurydice* Godm. (136 c) is a form from Ecuador the ♂ of which is above preponderantly bluish-grey beneath claret-coloured, on both surfaces with very dark markings; the ♀ is above dull brown, beneath yolk-coloured. — *castigata* Stich. from Peru and Bolivia does not differ considerably in the female above from specimens of *lucinda*, but it is darker and beneath more reddish; ♂ usually larger than the typical subspecies (*lucinda*), with the apex of the forewing being produced somewhat more pointedly. — *lucinda* and its forms are rather common, at open spaces in the woods, where they sit beneath leaves.

E. tenedia Fldr. (136 g). ♂ of the shape of the preceding species, but the upper surface mostly brown; the ♀ may be quite ochreous brown, but it may also exhibit on the forewing a whitish or yellow, band-like brightening which is differently shaped, mostly also differently coloured at every habitat (= ♀-form of *fasciata* Strd.). Beneath both sexes exhibit, instead of the coherent transverse lines of the preceding species, more scattered comma-streaks. From Mexico across Central America and the eastern parts of South America as far as South Brazil and Paraguay. Mexicans as well as quite southern animals are often much smaller than the figured ones. The species varies greatly. — *melancholica* Stich. is said to be larger than the typical form, above unicolorously intensely smoke-brown, the undulated transverse lines not very conspicuous, the median area scarcely darker, under surface lighter rusty brown, the transverse lines more distinct. South Brazil. Unknown to me. — *lupina* G. and S., described from Central America, though not bound to a certain district, shows a more grey upper surface, Mexicans from Misantla are of a bright red, the specimen figured by us forms the intermediary between the two. — *ravidula* Stich. is denoted by its author as a „faintly differentiated subspecies“, „on an average lighter, dull greyish-yellow to pale smoky-brown, with a somewhat rounder contour of the hindwing“. In the south of the range. — *cilix* Hew. described from Ecuador is smaller than *tenedia*, with more pointed, almost sickle-shaped forewings, a uniformly sooty-brown upper surface and a reddish-yellow under surface; the dark transverse stripes on both surfaces scarcer than in *tenedia*. — *sinuatus* Hew. with still more curved borders of the wings, likewise from Ecuador, may belong hereto.

E. angularis Hew. (136 g, as *angulata*). Recognizable by the wing-contour; the forewing somewhat concavely indented below the pointed apex, and the middle of the border on both wings projects geniculatedly. Ecuador, Bolivia and Peru.

- vulpina*. **E. vulpina** *G. and S.* is based upon 3 ♂♂ from Presidio in Mexico that are said to resemble *tenedius*, but to be of a brighter, red colour, almost like *fatima* (136 f). The wings above are scarcely noticeably ruled, the marking beneath is likewise obsolete.
- mandana*. **E. mandana** *Cr.* (= *polymenus F.*, *arminius F.*, ops. *Latr.*) (136 e). Entire with regularly shaped wings, above dark red-brown, beneath brownish-yellow with dark transverse streaks being united above to transverse lines. Specimens before me from Mexico (Guerrero) and those which I captured near Santos in South Brazil exhibit but quite faint differences (Mexicans are marked somewhat more distinctly). ♀♀ from Muzo and the adjoining Central America sometimes have a slightly geniculated border of the hindwing and more pointed forewings (*angulariformis Strd.*). — *furor Btlr. and Drc.* and *aurelia Bat.* from Maranhão likewise do not exhibit any difference worth mentioning. — *diogenia Prittw.* (136 e) from South Brazil are said to be smaller and lighter specimens, but it is just South Brazil where there occur especially large and dark specimens, and large and small ones are sometimes found resting on the same bush. — *mandana* is a common butterfly visiting particularly the flower-buds of blossoming bushes and flying all the year round in warm districts; from Mexico to South Brazil, Paraguay and Peru. — The ♀♀ are often considerably larger than the ♂♂. Beside typical *mandana* and *furor* there occur some more forms approximating *mandana* in Mexico; as for instance *tegula G. and S.* (136 f) which is about the most closely allied to *diogenia*.
- russula*. **E. russula** *Stich.* (136 f). Smaller than normal *mandana*, above duller and often darker, between the transverse lines „a grey, almost bluish-grey tinge“. Under surface light ochreous-yellow, the marking reddish-brown, finer than in *mandana*, the nebulous band before the border is absent, sometimes replaced by obsolete dots. The types originate from La Paz in Bolivia and from São Leopoldo in Brazil. — The marks are partly those of typical *mandana*, partly they are found in *mandana* from the most different countries; it is presumably scarcely a distinct species.
- fatima*. **E. fatima** *Cr.* (= *fatimella Ww.*) (136 f). Much more slimly built than *mandana*, with more delicate wings and of a burning brown-red (♂) or brown-yellow (♀) colouring. From Colombia to Brazil. Not rare.
- ocypore*. **E. ocypore** *Hbn.-G.* (136 g). Size and the shape of the wings of a small *mandana*, but the body much more delicate and the colouring on both surfaces dark nut-brown. Marking almost exactly as in *mandana*; Amazon, Peru. — *aethalia Bat.* from Central America and Colombia has a produced apex of the forewing and a similar anal angle of the hindwing and is beneath of a lighter colour than above; on the whole but little deviating. — *zelotes Hew.* originating from South Brazil and Paraguay has a red-brown ground-colour, similar as *mandana*; the ♀ entirely resembles a ♀ of *tenedius*, but it is more red-brown than dark yellowish brown, and the band in front of the distal-marginal part is not so very light. Whether *zelotes* is a subspecies of *ocypore* as which it has been dealt with, is doubtful.
- ovidius*. **E. ovidius** *F.* (= *fatima Cr. p. p.*, *cerea Hbn.*, *caeneus Stich.*) (136 h as *caeneus*). We choose this name of *Fabricius* being still vacant in the *Erycinidae*, because a yellowish-red *Emesis* has been undoubtedly figured by CRAMER as *fatima* and the name of *caeneus* was conferred on a small *Charis*, and therefore certainly a confusion would be inevitable. *ovidius* has, on a dark-brown ground, numerous silvery arcuate streaks which are united to a bossy chain. At the costa, before the apex of the forewing mostly a honey-yellow, light patch. From Guiana and Venezuela to Peru. Not rare.
- neemias*. **E. neemias** *Hew.* (137 a). Like the preceding species with silvery-blue arcuate streaks above, but dark blackish-brown, and easily distinguishable by the under surface being without any silver, whereas in *ovidius* also beneath the dark transverse streaks are silvery. Brazil, Paraguay, Bolivia and Peru; not common.
- poeas*. **E. poeas** *G. and S.* (136 f as *psoeas*). Recognizable by red-brown bands alternating with bluish-grey ones above. On regarding fresh specimens in the sun, we find that the upper surface is covered with single sparkling silvery scales. In specimens, where the long fringes are preserved, these also exhibit a faint lustre and are speckled, what is not to be seen on our figure. Beneath red-brown. Mexico; in the Tring Museum also from Zamora (Ecuador).
- brimo*. **E. brimo** *G. and S.* (137 a). Size of the preceding; forewing with a somewhat more pointed apex; upper surface dark brown. In the cell and the distal marginal part some lighter, faintly yellowish-brown patches, the disc of the ♂ with a cloud of a slight violet reflection. Very fine and sparse single, small silvery scales are scattered across the surface of the wings. Under surface rusty yellow, covered with dark punctiform streaks, except the distal marginal part. Colombia, and on the Chiriqui; often contained in the „Bogotá“-parcels. — *progne Godm.* (137 a) is somewhat smaller, the cloud with the violet reflection in the disc more lustrous, lighter, the distal margin of the under surface dark brown. Peru, Bolivia. Not rare.
- emesia*. **E. emesia** *Hew.* (= *yucatanensis G. and S.*) is not much larger than *progne*, has a strongly produced basal part of the costa, like a *Symmachia*, but almost exactly the colouring and marking of a *tenedius*-♀, except that the cell-end is traversed by a small bone-white band consisting of 3 adjoining spots. Mexico and the adjoining Central America; not common.

E. peruviana Lathy (137 a). Size of the preceding, but the upper surface of the wings greyish-brown; beneath the colouring of the forewings is rusty-red in the apical and costal parts, otherwise greyish-brown. The black transverse streaks and dots mostly arranged in rows. Peru.

E. temesa Hew. (137 a) is still somewhat smaller, the upper surface darker, so that the dark transverse streaks are less distinct. Distinguishable from the preceding by the bright brown-red under surface which is coloured almost like in *progne*, but darkened at the distal margin. From Ecuador. — **emesine** Stgr. *emesine*. are specimens from Pebas (Peru) with a red-brownish apex of the forewing above.

E. zela Btlr. (136 h). This common Mexican species being reported also from Colombia and Venezuela and, therefore, probably also occurring in Central America, has very pointed forewings and also a pointed anal part of the hindwing. Recognizable by the postmedian band above being brightened up in the forewing by a light greyish-brown, in the hindwing of a rusty-yellow colour. Under surface yellowish-red, similar as in *mandana*.

E. ares H. Edw. (136 h). Forewing dark brown with numerous small dark transverse bows; in the hindwing the whole costal half is of a burning red-yellow colour. North Mexico, Arizona. — **cleis** W. H. Edw. (136 h), also from Mexico and the adjoining Arizona, is lighter and more sparsely striated, but hardly different. — Here to may also belong **toltec** Reak., unknown to me, in which the costal-marginal part of the hindwing is no more rusty red, but similarly coloured as the rest of the wing. Likewise from Mexico; common.

E. cypria Fldr. (136 i) has the shape of *tenedia* (136 g), the forewing, however, exhibits a honey-yellow oblique band ending in the ♂ taperingly, in the ♀ broadly in the anal angle. North-western parts of South America; common. — **paphia** Fldr. is the northern form from Central America and Mexico, the oblique band brownish, broader, always regularly defined. In the ♀ the dark transverse markings above, at least those near the base, are less distinct and the oblique band is duller ochreous. — ab. **capnodis** Stich. (137 a) is a not rare aberration with a dull brownish oblique band of the forewing; in some places, as for instance near Onaca (Sa. Martha, Colombia), it flies together with typical *cypria*.

E. lacrines Hew. Here the oblique band of the forewing is bright yolk-coloured, a small oblong-ovate band extends from the costa to the upper median vein; the shape and size is that of *mandana*. Under surface bright brownish-yellow, towards the base greyer; ♀ similar to the ♂, duller, the oblique band more ochreous than orange-yellow. From Chontales (Nicaragua).

E. guppyi Kaye (142 a) has somewhat the exterior of a small *cypria*, but the oblique band of the forewing is here not orange-coloured, but dark brown, only quite faintly lighter than the ground-colour. On the under surface, however, the oblique band is distinctly orange-yellow on a red-brown ground. The black transverse dots only insignificant. Colombia, Venezuela; described from the Isle of Trinidad.

E. heterochroa Hpffr. (136 i). As large as *cypria* or larger, easily discernible by the yellow band of the forewing being broadened as far as near the distal margin, but being lengthways intersected by a dark nebulous band. Peru, Bolivia; not particularly rare.

75. Genus: **Siseme** Ww.

This genus contains extremely variable species. *S. alectryo* which is before me in about 200 specimens varies at every habitat in constant deviations, so that dozens of new forms might be described among the material before me consisting of far more than 1000 *Siseme* from the most various habitats. The *Siseme* are all small, elegantly marked, but mostly dark-grey coloured butterflies with a median band through both the wings. The head is broad, the forehead flatly arched, the eyes large, the palpi long but closely appressed to the head, so that they are not distinctly projecting on being seen from above. Antennae of more than half the length of the costa, gradually thickened at the ends to a feeble spindle. The *Siseme* are lively animals fond of flying in the sun on the slopes of mountains, where they come to the water in the morning and are easily taken there.

A. Border of the hindwing convex bulging out.

S. peculiaris Dre. (133 a) blackish greyish-brown; the forewings with small white oblique bands, the hindwing with a white longitudinal oval showing a different shape at every habitat. Peru, particularly on the Pozuzo not rare at altitudes of 800 to 1000 m. The white spot of the hindwing mostly extends beneath to the base.

S. alectryo Ww. (133 b). Blackish bluish-grey, in the centre of both wings a joint white fusiform band; between it and the apex of the forewing a small white oblique band being often indistinctly defined, between it and the border of the hindwing a similar, small, band-like spot; in the anal part of the hindwing 2 red, often confluent maculae. Colombia and North Brazil, as far as Bahia. — **tantilla** Thm. (133 b) has instead of the white distal spots only light grey, more linear brightenings traversing the whole hindwing as blurred lines; it also flies in Colombia, but different habitats from those of typical *alectryo*, as for instance

near Villavicencio. Here the small oblique band of the forewing is still fairly preserved; in a specimen captured by FASSL on the Rio Negro (East Colombia) also the white oblique band on the forewing is transformed into a grey line, the small fusiform band being very narrow. — *megala* *form. nov.* (133 b) is a form of almost double the size of *tantilla*, with a very distinct marking, deep colouring, and a broad median band; Monte Tolima and the Aguaca Valley. — In *spectanda* *Stich.* (133 b) the median band has turned a broad oval, the small oblique band of the forewing, however, to a small narrow stripe, the white distal spot of the hindwing only beneath distinct. Peru, Bolivia, Ecuador. — *transiens* *form. nov.* (133 b, c), a mountain-form from Bolivia, is smaller, with a still broader median spot, the small white oblique band of the forewing, which in *spectanda* is yet distinct and oval on the under surface, being here also nearly vanished. — It forms the transition to *lucilius* *Hpf.* in which the median band occupies almost the whole disc of the wing as a broad, below rounded oval, whereas the small white distal bands are absent altogether; this form is likewise found in Peru and Bolivia. — Not rare.

aristoteles. **S. aristoteles** *Latr.* (133 d). The two dark wings are traversed in the distal part by a band of short light rays which are particularly beneath distinctly prominent, in front of it a yolk-coloured median band being above and below pointed. Colombia (Monte Tolima). — In *ochrotaenia* *form. nov.* (133 d) from Loja in Ecuador this yellow band is broad and terminates broadly at the costa; — in *minerva* *Fldr.* (133 e) from the Rio Negro (Colombia) it is preserved as thin as a thread on the forewing, on the hindwing it has almost disappeared; — in *leucodesma* *form. nov.* (133 e) from the Rio Dagua (type in the Tring Museum) it is snow-white instead of yellow, in *sprucei* *Bat.* (= *nigrescens* *Mengel*) (133 e) it is shaded by grey. West Colombia. In Colombian *sprucei* the basal part of both wings is beneath light silvery blue; in *saturata* *Thm.* (133 e) from Ecuador, scarcely differing above, the whole under surface is dusted with dark (on our figure the two under surfaces of *sprucei* and *saturata* have been mixed up). Rather common.

B. Border of the hindwing between the apex and anal part drawn in or serrated.

S. pallas. This species resembles in different local forms almost all the forms of the preceding group of *Siseme*, so that on the whole the typical *pallas* corresponds with *lucilius* or *spectanda*, *pomona* with *sprucei*, *xanthogramma* with *ochrotaenia*, *albescens* with *leucodesma* etc. All the *pallas*-forms, however, are at once distinguished by the border of the hindwing being distally not round, but rather drawn in. — *pallas* *Latr.* (= *aristoteles* *Stgr.*) (133 c) is the form with a fusiform, in the middle broadly white median band; from Venezuela and North Colombia. — In *angustior* *form. nov.* (133 c), from considerable altitudes (Monte Tolima etc.) in Colombia, the median band is narrowed almost to one half, sometimes to one third. — In *pomona* *G.* and *S.* (133 c) lying before me from the Rio Negro (Colombia) the band is shaded with grey. — In *xanthogramma* *Bat.* (133 d) the median band is yolk-coloured, from the Rio-Negro in Colombia. — *atrytone* *Thm.* (133 d) exhibits half the median band yellow (Bolivia) or ochreous with a whitish brightening in the middle (Pozuzo, Peru), sometimes also nearly all white (*albescens* *Stich.*) from Ecuador and the neighbouring districts. — With respect to the width and pointedness of the fusiform median band, the species at every habitat exhibits certain, quite constant peculiarities. The butterflies are common.

neurodes. **S. neurodes** *Fldr.* (133 c). Very similar to the preceding species; smaller, recognizable by the broader red anal band and by the much more intense and longer white rays in the distal part of the under surface of the hindwings. I know this form only from Peru. — From Bolivia and Colombia, as well as from the Pozuzo (Peru) a more dark slate-blue form is known with the anal part of the hindwing being more extended and ending into a sharp tooth; to this form, *caudalis* *Bat.* (133 c), however, there are transitions found. — Common.

pedias. **S. pedias** *G.* (133 d) does not entirely belong to this genus and might form a connection with the *Ancyluris*-group. The total appearance reminds us of *pallas*, but the light patches, particularly beneath, show a bright hyacinth-blue reflection; the small red anal band of the hindwing varies in shape and width. Before me only from Bolivia; mostly from the Rio Songo. Apparently rare.

pseudopal-
las. **S. pseudopallas** *Weym.* (= *hellotis* *Thm.*) (133 b). Greatly resembles *pallas*, but the median band of the forewing is more bone-yellow, above not pointed, but broadly reaching the costa. Beneath in the distal part of the forewing instead of the band formed of rays a white transverse line. Peru. — In *hyperion* *form. nov.* (133 a) being only half as large, from Huayabamba, the median band is anteriorly greatly narrowed and terminates behind in the middle of the hindwing. Not rare.

Note. *A. Siseme* from Argentina has not become known to me. Regarding *S. hothurus* *Bg.* cf. Additions.

76. Genus: **Drepanula** *Röb.*

The genus is not closely allied to any other. The species described first was dealt with as *Lemonias*, but RÖBER combined its characteristics deviating from the *Lemonias*, already in 1892. From *Ematurgina* to which STICHEL allies the genus the subcostal system deviates essentially, the neurulation corresponds rather with *Siseme* which, however, shows again a greater variability of the veins, although it undoubtedly represents

a well defined genus. *Drepanula* resembles *Baeotis* particularly by the shape of the wings, the structure of the body and the habits, though there is no close connection between the two genera.

D. calvus *Stgr.* (133 e) from Peru has a very falciform apex of the forewing and a unicolorously slate-grey upper surface; the distal margin, a median blurred spot at the costa and a costal triangle before the apex darker; in front of the border a series of white dots. Under surface marked very white, in the median area shaded in grey. Peru.

D. gerres *Thm.* (133 f) entirely resembles the preceding, above the dark clouds are more defined, the hindwings somewhat brighter. Quite different is the under surface, being unicolorously bluish-white with numerous small black dots. Colombia, before me from Muzo and Cananche.

D. lencates *Hew.* is smaller and the forewings are above quite sooty black except a small light longitudinal spot at the middle of the inner margin; the hindwings are in the middle entirely white only the base and the distal-marginal third are black. Unknown to me; may not belong into this genus; described without the patria being mentioned.

77. Genus: **Dinoplotis** *Stich.*

The genus is established for a small species unknown to me, having about the shape of the preceding genus, „but somewhat more circular hindwings“. One species from STAUDINGERS collection described from the Amazonas. In the veins of the forewings there is a conspicuous anastomosis between the costal and the second subcostal vein, in which may be seen the stunted remainders of the first subcostal vein.

D. orphana *Stich.* Size of *D. gerres*; upper surface quite unicolorously drab, only in the apical part of the forewing deeper blackish. Beneath the forewings exhibit small white spots at the border below the falciform apex and at the cell-end; the hindwings are beneath yellowish-grey, with a light median band shaded in black. From Massauary.

78. Genus: **Parnes** *Ww.*

The two small brownish-grey species belonging hereto are very much alike each other; they are above blackish-brown, beneath in the apex of each wing is a black eye-spot provided with 2 white pupils. The costal of the forewing runs for some distance together with the first subcostal vein. The animals are not common; nothing is known to me about their habits.

P. nycteis *Ww.* (138 f). This is the smaller species; fresh specimens have an entirely unicolorously black upper surface; only in much flown specimens the colouring of the under surface shows faintly through, as in our figure. This colouring is dark brownish-grey, finely striated in yellow, before the apex in the forewing and hindwing small, white-pupilled eye-spots. Panama to the Amazon.

P. philotes *Ww.* (138 f). Larger, above sooty black, beneath dark grey, with 1 large eye-spot with 2 white pupils near the apex of all the 4 wings; some more small dotted eye-spots at the distal margin of the hindwing. Guiana, Amazon.

79. Genus: **Zabuella** *Stich.*

This genus is based upon a rather unicolorously grey animal which was described as *Lemonias*, but has evident connections with *Ematurgina*. The most conspicuous mark in the animal is a very thick knob of the antenna, which is hollow in the shape of a spoon, like in an *Argynnis*. Otherwise the shape is like that of the following genus, and both these genera belong to the southern part of the neotropical region.

Z. tenella *Burm.* (138 k). Dirty greyish-brown with a series of dull dotted eye-spots in front of the border and an irregularly curved median shade across both wings. Under surface dirty grey with black-pupilled, small eye-spots near the base and the border, and a chain of dark spots across the centre. Argentina, local, but numerous at the flying-places, as for instance near la Soledad in the Misiones and at other places.

80. Genus: **Ematurgina** *Röb.*

Three species, one of them greatly deviating, form this genus. They have long, projecting palpi, feebly thickened, not very long antennae, remarkably broad wings, the forewing with a stretched costa and four-branched subcostal, the two last branches of which form a fork with a long stalk. The compact abdomen reaches the anal angle of the hindwings, though it does not project beyond it. The butterflies are not common.

E. bifasciata *Meng.* (= *mabildei* *Röb.*) (140 e). Blackish-brown, with 2 parallel, ochreous oblique bands, being several times interrupted, through both wings, and with small ochreous spots before the border. Beneath like above. South Brazil and Paraguay. — In *ochrophlegma* *Stich.* the yellow markings are expanded; Argentina. Our ♀-figure, according to a specimen from GOYAZ, forms a transition to it.

- axenus.* **E. axenus** *Hev.* (140 e). Very similar to the preceding species, the bands above broader, in the ♀ also lighter yellow. The under surface, however, not like above, but the costa of the forewing and the base are also yet yellow, so that this colour outweighs the dark one. South Brazil.
- leucotopus.* **E. leucotopus** *Stich.* This species inserted here by its author has a white discal and submedian spot of the greyish-brown forewings and white hindwings bordered in grey. The under surface has more white. We figure a ♀ from Buenavista (Bolivia), which has a small white spot in the anal angle of the forewing and a light patch in the border of the hindwing (= subsp. **emphatica** *Stich.*) (140 e). Typical specimens as they lie before me from Tarapoto (Coll. BANG-HAAS) have this light patch somewhat duller, and the white spots of the forewings are smaller.

81. Genus: **Apodemia** *Fldr.*

This genus consists of about a dozen species showing a remarkable, though only superficial resemblance with *Melitaea*. A likeness with the genus *Stalachtis* seems to be due to mimicry, though it is distinct enough to deceive even eminent experts, so that one species was described as *Stalachtis*. The genus is absent in the supertropical forest-district, occurring only from Mexico to the north and again far to the south. The veins do not exhibit any deviation from the general type of the American *Erycinidae*.

- nais.* **A. nais** *Edw.* (141 g). Reminds us of a *Melitaea* of the *didyma*-group, also beneath; a distant resemblance with our *Nemeobius* may be only secondary. Bright reddish-brown, spotted in black, behind the middle below the costa, in the ♀ mostly also above the proximal margin, small whitish spots. — The green, turban-shaped egg with an hexagonally netted upper surface yields the larva which, being full-grown, is drab, across the dorsum with whitish-yellow spots and fluffy hairs, the shape being something like that of a wood-louse, flat and posteriorly pointed. It feeds on wild plums. Pupa dark brown, fastened by the cremaster and held loosely by a belt. Mexico and the southern states adjoining to the north of it. Not rare; fond of the open country.
- mormo.* **A. mormo** *Fldr.* (= *dumeti* *Behr.*, *mormonia* *Bsd.*) (141 d). Somewhat smaller, with copious white dots on a blackish-brown ground, the disc of the forewing reddish-brown. Beneath the hindwings are almost
- virgulti.* white, with blackish markings. California to New Mexico; not rare. — **virgulti** *Behr* (♂ *sonorensis* *Fldr.*) (141 e) has above in the hindwing a reddish-yellow band and on the under surface of the hindwings intensely blackish-brown shades; South California and Mexico. — **cythera** *Edw.* (141 e) has almost the whole ground of the hindwing tinged with reddish-yellow; the white spots are enlarged and assume, particularly
- cythera.* on the under surface of the hindwing, an oblong, more radiatiform shape. Arizona and Mexico. — **druryi** *H. Edw.* (= *druryi* *Edw.*) (141 d) is above lighter yellowish-red, the black and white spots are reduced.
- druryi.* New Mexico. — **maxima** *Weeks* (141 e) which may perhaps deviate little or not at all from **mejicanus** *Behr*
- maxima.* being unknown to me, is not only larger than the other forms of *mormo*, but also than the *nais* resembling
- mejicanus.* it. Here the whole ground of the wings is yellowish-red, the white spots not radiatiform, but like in *druryi* bordered intensely in black, the black being united to irregular bands. North California. — Local, mostly not common.
- palmerii.* **A. palmerii** *H. Edw.* (141 e, f). Much smaller than the preceding, about comparable with the European *Melitaea asterie*. Blackish-grey, finely spotted in white, between there are small red-brown spots on the hindwing. Under surface marked like the upper, but of a dull ochreous-grey, white-powdered ground-
- hypoglauca.* colour. — **hypoglauca** *G. and S.* (141 e) not lying before me in nature, is reported to belong hereto *); it has above an iron-grey ground-colour, without white spotting; beneath yellowish-white, with rows of dark spots and lines. — The larva looks almost like a small *nais*-larva; on *Beleperone californica*. Western parts of the southern states and Mexico. — Local, but not rare.
- hepburni.* **A. hepburni** *G. and S.* (141 f). The smallest species of the genus; forewings reddish iron-grey, sparsely spotted in white, the under surface almost ochreous-yellow with white spots being faintly bordered in dark; differing from *palmerii* by the lighter, more reddish upper surface, a sparser white spotting and a paler under surface. Mexico, the figured ♀ from Sonora.
- walkeri.* **A. walkeri** *G. and S.* (141 f). Above grey, the bands and spots somewhat lighter, but not white; under surface with quite a faintly pale ochreous tinge. Mexico, local, but in some places very common. Specimens from Oaxaca are beneath more intensely marked in black; in those from Tehuacan the pale-yellow tinge is nearly altogether absent.
- multiplaga.* **A. multiplaga** *Schs.* (141 e). Much larger than the preceding, the spots of the upper surface of a pure white, the anal angle of the hindwing forms in the ♂ an apex provided with a fringy beard. Basal half of the hindwings beneath almost white. New Mexico. Rare.
- carteri.* **A. carteri** *Holl.* (141 a) from the Bahama Islands deviates somewhat from the other *Apodemia*, like the following species. Our figure most exactly reproduces the original. Under surface more dark greyish-brown with small blackish transverse spots in the forewing and small transverse streaks in the hindwing. In the anal angle of all the 4 wings a large, round, black spot.

* It probably belongs rather to *walkeri*.

A. stalactioides *Btlr.* (141 f, misprinted into *stalachtoides*). Forewing somewhat less pointed, other- *stalactioides*. wise of the shape of the preceding, but above the black wings exhibit white spots, with a brown base of the wings and a brown antemarginal stripe. Ground-colour of the under surface preponderantly red-brown, much more copiously and densely spotted in white than the upper surface. São Paulo, Rio de Janeiro. — **canidia** *Drc.* is the smaller, more northern form (Central Brazil) with a preponderantly black ground-colour. *canidia*. — The species is always recognizable by the abdomen being above of a silky lustrous white beginning at the third ring. It imitates *Stalactis susanna* from the same habitat. Rare.

A. castanea *Prittw.* (141 f) somewhat resembles above *Calydna punctata* (136 a) and *Cremna actoris castanea*. (126 h) with which it flies together, but the light dots are transparent like glass, not so brightly white, as they appear in our figure. Beneath something like *Zab. tenella* (138 k) of which it has also the same faint median shade of the upper surface noticeable in a certain exposure to light. South Brazil; rare.

82. Genus: **Hamearis** *Hbn.*

Butterflies with an exterior like small *Phyciodes* and certain Hesperids flying in their patria. The genus is only with difficulty separable from *Apodemia* with which it is combined by some. The body is robust in the larger species, the abdomen of the ♀♀ stout and long. In the ♂♂ the upper surface is mostly yellowish-brown with dark spots; the under surface of the hindwings is adapted to bark or stones. The palpi are long with a long, thin, styloid terminal joint projecting anteriorly beyond the head; the veins of the wings not deviating from those of *Apodemia*. They inhabit the Pampas in the south and the Llanos in the north, being mostly local and varying greatly already at short distances, but not rare at their flying-places.

H. epulus *Cr.* (141 b). This is perhaps nothing else but the *zachaeus* *F.* Above blackish, with few *epulus*. small white spots in the disc of the forewing and a dull red-yellow macular series in front of the border. Guiana. In specimens from Para also the ♂♂ exhibit much more red-brown, so that this sometimes occupies the greatest part of the disc of the hindwing. — **campestris** *Bat.* (= *propitia* *Stich.*) (141 b as *propitia*) has *campestris*. somewhat larger discal spots of the upper surface, which are also increased and all brown-red. From Itaituba and São Paulo di Olivença. — Bolivian specimens have the spots above bright light orange-coloured, almost like *erostratus*; also the under surface of the hindwings, forming in *campestris* on a violettish-brown ground in the middle a faint cloud out of tiny yellowish, mostly round spots, is in Bolivians more variegated, but more confused. — In **signata** *Stich.* (141 b) the small spots above are increased, but nearly all, also those *signata*. in front of the border, are whitish instead of reddish-yellow; South Brazil, North Argentina (Salta). — Still more white-spotted, and with another under surface (hindwings beneath whitish, finely shaded by grey and brown) are the very small **minuscula** *Giac.* (142 h) from la Rioja, in West Argentina, of which there *minuscula*. is before me a form being somewhat more variegated beneath, from San Ignacio (Misiones, East Argentina). In the open grass-districts, not rare.

H. notialis *Stich.* is known to me from *STICHELS* figure; above like *erostratus* (141 a) duller brown- *notialis*. red, of the yellowish-red band in the apical part only dull marks are noticeable, the hindwings beneath yellowish-grey, in the middle a whitish, black-tinged, tooth-like spot. Argentina.

H. erostratus *Ww.* (141 a, b). Above yellowish-red, with a blackish-brown distal part in which a *erostratus*. yellowish-red oblique band extends in front of the apex and behind it in front of the border a yellowish-red macular chain. The under surface of the hindwings exhibits on a brown ground 2 yellowish-white transverse bands converging at the proximal margin. Venezuela (on the Orinoco), Colombia, Panama, on grass-plots, very common. — Near Merida in Venezuela occurs a form of double the size, in which the light transverse bands of the under surface of the hindwings begin to be divided into large whitish spots; it is **antaeus** *form.* *antaeus*. *nov.* (141 b), presumably only an alpine form of the preceding. Type in the Tring Museum.

H. chilensis *Fldr.* (141 b). Light yellowish-red, the whole apical part of the forewings black with nar- *chilensis*. row, adjacent, small bands of the ground-colour; the under surface white, with confused grey and brown embeddings. The Andes of Chile and Argentina.

H. cisandina *sp. nov.* (141 d) is larger, in both sexes resembling the preceding above, but beneath *cisandina*. much darker, so that the yellowish-red on the forewings beneath and the white on the hindwings beneath appears only inserted in smaller spots. Argentina (Chaco de Santiago del Estero, on the Rio Salado).

H. middletoni *E.-Sh.* (141 a). Above more or less dull brownish-red, with blackish spots, the distal *middletoni*. margin likewise black. Immediately recognizable by the under surface of the hindwings, in which numerous bone-white, partly black-pupilled, small oval spots are arranged to 2 or 3 regular arcuate rows. South Brazil and Paraguay.

H. dovina *Schs.* (141 c). One of the largest species, above red-brown, forewing in the disc spotted *dovina*. dark, hindwing with a dark base, both wings have in the broadly blackish marginal area a chain of black-pupilled eye-spots of the ground-colour. The under surface reminds us of that of *middletoni*, but the white spots and markings are larger and not so numerous. Argentina and Bolivia.

- domina*. **H. domina** Bat. is just as large a species, above the ♂ likewise red-brown and similarly spotted; the ♀ before the apical part with a whitish-yellow macular band. Under surface marked somewhat differently; the species has hitherto only been known from Central America.
- aurinia*. **H. aurinia** Hew. (141 a) resembles the preceding species, being also about the same size, but blackish above; the forewings white and with rusty-red spots, recognizable by the brown, not white-spotted under surface of the hindwings. Brazil. — **incana** Stich. from Peru is larger, the hindwing above lighter ochreous, beneath we see instead of insignificant black transverse markings in the brown, in the ♀ light-clouded disc, distinct black, oval rings. — **gauchoana** Stich. from Uruguay is not before me; it is said to be smaller, on both surfaces lighter, with a red-yellow ground-colour of the forewings, the hindwings with smaller submarginal spots, otherwise nearly one-coloured, only in the basal and costal areas somewhat darker. Transitions of it also in Rio Grande do Sul.
- colchis*. **H. colchis** Fldr. (140 h). This species is on both surfaces considerably darker than *aurinia*; the spots in the ♂ ♂ are above sparse, also the under surface of the forewings very sparsely spotted at the apex and distal margin; the hindwings beneath dark brown with smaller eye-spot markings. Brazil.
- albinus*. **H. albinus** Fldr. (140 h, 141 a). Very variable, deviating at every habitat, particularly Panama-specimens (our figure of the under surface) differ entirely from those from Sa. Marta (141 a, upper surface) which are by far larger and beneath marked rusty-yellow instead of dark brown. Recognizable by the almost white upper surface of the disc of the wings. Not rare at its habitats; Panama to Venezuela.
- ochracea*. **H. ochracea** Mengel (141 d). Our figure exhibits specimens from Sapucay. Beneath the wings are cancellated in black almost like *Melitaea*; a median macular band of the hindwings is bone-white in the ♂, in the ♀ rusty-yellow. Paraguay; the butterfly seems not to be common; it flies in the company of certain *Stalactis* (*sontella*) which it apparently imitates.
- theodora*. **H. theodora** Godm. (142 g), described as a probable *Riodina*, is inserted here by STICHEL. The ♂ differs from the figured ♀ by an oblique stripe being above yolk-coloured, beneath bone-white and running from the middle of the costa of the hindwing to its proximal margin. From Chapada in Brazil.
- albofasciata*. **H. albofasciata** Godm. (142 g) resembles the preceding, but the spots of the forewings are white also in the ♂, the discal ones placed more medianly, the oblique streak on the hindwing above distinct only in the costal part, beneath, however, running broadly to the middle of the inner-margin. Smaller than the preceding species. Corrientes and Cordoba in Argentina; Paraguay.
- cinericia*. **H. cinericia** Stich. Described according to a single ♀ from Argentina, is neither figured nor compared with a noted form. „Shape like that of the preceding“ (*notialis* and *albinus*); the size seems to approximate that of *epulus*. Upper surface dark ashy-grey, forewing with 3 small black spots in and behind the cell, between the distal ones the ground-colour is brightened up by whitish; distally from the cell a strongly angled row of whitish spots. Hindwings almost one-coloured, only at the border somewhat lighter and with a row of indistinct black dots. Beneath grey, forewings partly somewhat dull ochreous-yellow, the spots as above, more distinct. Hindwings with indistinct dark transverse lines, median area lighter, distal area costally somewhat grey, otherwise greyish-brown, gradually shaded lighter with a fine black marginal line and indistinct submarginal dots. — Unknown to me.
- guttata*. **H. guttata** Stich. according to a single ♀ from Mendoza in Argentina. Seems somewhat to resemble the ♀ of *epulus*, but is said to have conspicuously short palpi. Scheme of markings similar to that of *epulus*. — Unknown to me.

83. Genus: **Metacharis**.

Like in *Ematurgina*, also in *Metacharis* the anterior radial vein most peculiarly branches off only from the 3rd subcostal vein, instead of from the anterior cell-end, its basal part being grown together for some distance with that of this subcostal vein. Remarkable is the very long costal margin of the forewing; also that of the much smaller hindwing is relatively long. The ends of the veins are in nearly all the forms marked with greasy-lustrous pencil-streaks. The species mostly are common; in day-time they sit on the under surface of leaves with their wings spread out and the palpi stretched straight forward; on being chased away by beating they only fly for some paces following the forest-road, and are thus easily taken. 10 species are known.

- nigrella*. **M. nigrella** Bat. (= *sylves* Hew.) (137 c). Above blackish olive-coloured (♂) or dark olive-grey (♀) with small black transverse streaks and marginal dots. The dot in the apex of the forewing is the thickest and often (in the ♀) on a rusty-red cloud. Venezuela, Colombia to Peru. Not rare.
- cuparina*. **M. cuparina** Bat. (137 c) is smaller, above deep red-brown, beneath in the ♂ uniformly lustrous blue.
- victrix*. Colombia to Peru. — **victrix** G. and S. (137 c) are ♂♂ from Central America, the almost black upper surface

of which exhibits a wonderful ultra-marine blue lustre and often also orange-red, small distal spots. — **xanthocraspedum** Stich. (137 c) which we figure from Cachabé, are ♀♀ with a faintly olive-brown tinge on the upper surface and a broadly yellowish-brown distal band of the hindwing. — Not rare.

M. regalis Btlr. (♀ = *auria* Drc.) (137 b) has the upper surface similarly coloured as *victrix*; but the ♂ is beneath similarly coloured as the ♀ on both surfaces, i. e. red-brown, with black spots, whereas the ♂ of *victrix* looks blackish-blue beneath. Venezuela (Suapure), Colombia (Villavicencio) to Bolivia and Peru. Colombian specimens are beneath lighter red-brown than Peruvians. — **indissimilis** Weeks (137 d) is a form being above olive-brown, from Colombia, with a rusty-yellow (*rabutana* Stich.) or ochreous-yellow diffuse spot in front of the apex of the forewing.

M. ptolomaeus F. (= *agrius* Dalm., *sylvestra* Mén.) (137 b, misprinted in *ptolemaeus*). Here both sexes are above red-brown, the under surface, however, in the ♂ black, with a blue reflection, the basal part of the wings powdered with a whitish blue. *ptolomaeus*-♂ is coloured contrarily to the preceding species, since the upper surface of *ptolomaeus* resembles the under surface of *regalis*, and the under surface of *ptolomaeus*-♂ the upper surface of *regalis*-♀. From the Amazon to South Brazil. Common.

M. lucius F. (= *nicaste* H.-Schäff., *batesi* Btlr.) (137 b). Above coloured and marked almost like *nigrella*, but much smaller, the forewings posteriorly broader and the border of the hindwing almost straight. ♂ beneath grey-blue, with a lilac reflection, ♀ beneath rusty-yellow, similar to that of *ptolomaeus*, but the base of the wings not powdered with white as there. Guiana to Brazil. Common.

M. chia Hbn. Smaller than *lucius*, the pencil-streaks of the veins thicker and shorter, the upper surface deep dark-brown, but at the lower distal end of the disc of the forewing is a small orange spot. The under surface is light yellowish-brown, the wings dotted in black and broadly margined in dark. I only know HUEBNER'S figure which was inserted here by reason of the pencil streaks, but which otherwise resembles a *Crococxona*. Guiana.

M. exigua Bat. is said not to be the ♀ of the preceding species, but closely allied to it. Above brown with small, cornered darker brown spots, and with less numerous, small orange spots between them; in front of the border a series of darker orange-brown bordered spots. Beneath brownish-yellow, spotted like above. Size of *lucius*; described according to 1 ♀ from the Tapajoz; unknown to me.

M. erotylus Stich. (137 k). Blackish, hindwings in the basal part covered with red-brown; recognizable by the orange spot of the forewing, the base of which occupies the whole inner margin, and which then extends anteriorly, twists inwardly and grows narrower, in order to end taperingly at the middle of the costa. On the under surface the forewing is similar as above, but the hindwings are dusted greyish-brown and covered with dark commastreaks. The pencil-streaks on the ends of the veins are in the ♂ distinct only on the hindwings above; in the dark-brown, yellow-spotted ♀ they are on both wings. Peru, Bolivia.

M. erythromelas Sepp (137 d). The ♀ already greatly resembles some ♀♀ of the next genus (e. g. *Leimonias emylus*). Dark, with an ochreous-yellow, irregular oblique band of the forewing. Behind this oblique band there are 3 to 5 small white diffuse spots, which occur also in the ♂, though only beneath. The ♂ is above black, only the basal half of the forewing (except the costa) and a slight flush at the base and inner margin of the hindwing are miniate, at least I myself consider such butterflies from Guiana to be the typical ♂♂ of *erythromelas*. — In the form **erythraea** Stich. from Espiritu Santo, unknown to me, the red is more extensive, and the description mentions a yellow ring-spot near the apex.

M. poeciloptera G. and S. (137 d) has in the ♂ somewhat more red than the preceding species, so that the proximal half of the wings may be called red, the distal one black. — **melusina** Stgr. (137 d) differs scarcely from it. The ♂ has the greatest part of the hindwing black. — Larva white, fluffily haired in white, on *Viscum verticellatum*; the pupa brown, fluffily haired in white (Sepp).

84. Genus: **Lemonias** Ww.

This adopted name is to be preferred to the *Polystichtis*, as no other genus of animals is called so, and it can by rights not pass as such. Neither the veins, nor the legs nor antennae call for a division into further genera; nor does the formation of the palpi give sufficient reason for a separation; according to STICHEL an examination of the copulation-organs resulted in „insufficient conclusions“. There remain, therefore, merely exterior differences of the habitus to which we attach little importance. Thus the genus remains on the whole in the limits assigned by WESTWOOD and the older authors, such as BATES and KIRBY. — Hereto belong graceful, mostly brightly coloured, rather small butterflies with a long, slender body, mostly rather glaring colours of the upper surface and a one-coloured, often white under surface decorated with tiny dots and streaks. The ♀♀ mostly greatly deviate from the ♂♂, frequently with an oblique band of the forewing. The under surface and still more the shape and colouring of some ♀♀ exhibit a close alliance to *Echenais*; sometimes to such an extent that one might be inclined to regard the separation of the two genera to be not quite natural.

- rhodope*. **L. rhodope** Hew. (137 e) resembles *Metach. melusina* above, but the under surface is marked very similarly to that of *emylus*, though it is duller violettish-green. The ♂ is unknown to me; the specimen figured as *ancile* by HEWITSON may perhaps belong as ♀ to *rhodope*; the forewings are similar, more orange-coloured, but the hindwings are unicolorously blackish-brown and the under surface is marked differently. I was not able to obtain two equal ♂♂; the boundary between the black and red of the upper surface varies at every habitat. Amazon. — *bubo* Btlr. has near the anal angle before the black distal margin a small white spot, while the ♀ (according to BUTLER) has a kind of a light spot in the middle of the dark-brown hindwing. — *amphis* Hew. (137 d) are specimens with a greatly narrowed margin of the hindwing.
- cerealis*. **L. cerealis** Hew. (♂ = *cuprea* Btlr.) (137 g). ♂ brick-red in the cell and before the border, some specimens also in the disc with black markings. Before the apex little spots of a blue lustre. ♀ dull yellowish-red, with a panther-like, copious marking. Under surface of the ♂ similar to that of *emylus*, more one-coloured leaden-grey. Extremely inconstant, differently marked at every habitat, also the ♀ in which the spotting in the disc of the forewing may disappear nearly altogether (= *caecina* Fldr.). From the Amazon, rather rare.
- zeanger*. **L. zeanger** Stoll (137 g). Presumably scarcely specifically different from the preceding species which it replaces in Guiana. Typical *zeanger* resemble *cerealis*, but the bluish-lustrous apical spots of the ♂ are increased. Surinam. — *rhesa* Hew. has the blue spot larger, more metallic, more remote from the apex, whereby a certain exterior resemblance is created with *Argyrogramma amalfreda physis* Stich., so that the figure of the latter was denoted by mistake as *rhesa*, although the blue-silvery line in front of the border of the forewing shows that it must be a *physis* with which also the marking at the border of the hindwing corresponds. — *pirene*. **pirene** Godm. (137 g) from the Upper Amazon has the black apical part of the ♂ forewing increased and traversed by a broad blue band, and in *gyges* Stich. (137 g) from Humayta (Amazon) and Peru the blue spot is still larger, so that it occupies nearly the whole distal half of the forewing, and the dots in front of the border of the hindwing are partly confluent. Varying at every habitat and representing an almost uninterrupted series of transitions. Not common.
- parthaon*. **L. parthaon** Dolm. (= *thermodocē* Hbn.-G., *rhesa* Btlr. p. p., ♀ = *ancile* Hew. p. p.) (137 e, as *parthaon*). Here the red on the forewings has disappeared except a minute spot before the anal angle; the ♂ has blue, the ♀ white spots before the apex of the forewing; described from Guiana. — *pelarge*. (137 e) scarcely differs from *parthaon*; the blue spot of the forewing is said to be smaller, but it varies in both forms; as a chief difference the black colouring of the abdomen in *pelarge* (from Mexico and Central America) is mentioned, which, however, occurs also in Amazon-specimens. — Rare.
- florus*. **L. florus** Stgr. (137 k). Approximating the preceding species, but the red of the hindwing shaped into an oval disc before the distal margin. The forewing brown, with a diffuse, bluish-violet lustre, above the basal inner-marginal part with a reddish gloss. The ♀ with a pale yellow oblique band of the forewing. Ecuador to Venezuela.
- lasthenes*. **L. lasthenes** Hew. (137 i, k) greatly approximates the preceding, but in the ♂ the orange-yellow band of the hindwing, in the ♀ the bone-yellow band of the forewing is shaped differently. Central America. Rare.
- zeurippa*. — **zeurippa** Bsd. greatly resembles *martia*; on the forewing the violet reflection of the apical part does not extend proximally beyond the centre of the wing; the orange-brown anal spot of the hindwing is shorter, broader, rounder, the animal as large as *lasthenes*; the ♀ like in *lasthenes*, but the band of the forewing with a slight ochreous tinge and curved. Mexico and Honduras.
- martia*. **L. martia** Godm. (137 k) is allied to the preceding, larger; the ♂ with a more intense reddish tinge, the apical part of the forewing of a bright violet lustre. The ♀ is unknown to me. Described according to a single ♂ from Colombia (Rio San Juan).
- sudias*. **L. sudias** Hew. nec Stgr. (137 k). In the ♂ the disc of the forewing is entirely suffused by blue, the border of the hindwing broadly orange-yellow. The ♀ resembles those of *florus* and *lasthenes*, but the oblique band of the forewing is white and does not reach the anal angle, quite similarly as in the ♀ of *argemissa* (137 i). Mexico and Central America. Rare.
- apotheta*. **L. apotheta** Bat. From „Brazil“, without the habitat being more explicitly mentioned, unknown to me. Upper surface dark ochreous-brown, the wings traversed by few short, fine, darker streaks, the marginal part with a reddish tinge, in front of the border a regular row of dark, light-encircled dots. — *maeon*. **maeon** Godm. (137 h) from Guiana has a darker apical part of the forewing and a greyish-white under surface; — *maeonides*. in **maeonides** Godm. from Colombia (137 h) almost the whole forewing, except the narrow inner-marginal part, has a dark tinge, and the under surface is light slate-grey, without a very dark border. — *idmon* G. and S. from Panama and the adjoining Colombia entirely resembles *maeon* (137 h), but the darkening does not cover the costal and apical parts, but it extends also above along the distal margin and is not intense. The ♀ is larger, more dirty greyish-brown, uniformly coloured, with distinct black markings. Beneath like *maeon*, but the margins are developed more distinctly. Rare.
- arachne*. **L. arachne** Stich. I do not know; it is said to be like *idmon*, the wings above rusty-brown with 3 rows of black streaks; forewings with dark brown spots and obsolete whitish submarginal lunae, hindwings with

white posterior half and black marginal dots. Beneath marked just the same with a brownish-grey ground-colour in some parts mixed with white. Amazon.

L. argenissa Stoll (= *petronius* F., *sudias* Stgr., *staudingeri* Godm.) (137 i). In the ♂ the whole upper surface is suffused with violettish-blue, narrowly marked with black; ♀ greyish-brown with a white oblique band of the forewing ending broadly before the anal angle. Colombia, Panama.

L. fannia Godm. (137 i) is known to me only from GODMAN'S figure of the ♂. Above dark brown, the distal part of the hindwings violettish-blue; under surface with small blackish streaks in the disc, a dull band before the border and dark-pupilled eye-spots before the border of the hindwing. Guiana.

L. laobatas Hew. (= *labotas* G. & S. p. p.) (137 h). ♀ blackish-brown, in the apical part of the forewing and before the border of the hindwing sparsely spotted in white, in the disc of both wings small black dashes. ♂ very similar to the figured **andraemon** Stich. (137 i), but the upper surface of the ♂ more reddish than blackish-brown (= **trötschi** G. & S.), the under surface more shaded and streaked in dark. Colombia and Panama. — **simplaris** Stich. from the Amazon is smaller than *laobatas* and has no white intermixture in the forewing; in the hindwing the white is increased, but the blue is absent.

L. caligata Stich. Shape of the wings like in *idmon*, the anal angle of the hindwings somewhat more rounded. „Upper surface greyish-green, under surface light-blue, on both surfaces black spots, the position of which corresponds with the general scheme of markings of the genus.“ In the hindwing besides 2 more spots near the costal margin on a grey ground. Near the margin of both wings a scarcely appreciable silvery line. Beneath all the spots are smaller. Rio San Juan (Colombia).

L. antanitis Hew. probably does not belong into this genus (rather to *Pandemos*), in case HEWITSON'S figure really represents a ♂. Snow-white, forewing with a broad black marginal band ending broadly in front of the anal angle. A black wedge runs from the base of the forewing to the cell-end along the costa. Hindwing quite snow-white. Under surface with a brownish median shade being broad at the costa of the forewing, and an undulate brown line in front of the marginal part. It resembles on the whole a white *Dynamine* (101 A a). Bolivia.

L. byzeres Hew. (142 d). Above brown with fewer darker dots and streaks corresponding about with those beneath. Brazil.

L. luceres Hew. (142 d). I doubt whether it belongs hereto. The under surface like the upper one, but orange-red and the white subapical spot of the forewing larger. Ecuador. Somewhat homochromous with certain Geometrids from that region (*Devarodes*).

L. pione Bat. (137 h). Deep blackish-blue, above with numerous, small dark spots and dashes. It faintly reminds us of an *Emesis ocyppore* (136 g), but it is smaller and more lustrous. Para.

L. pulchra Lathy (137 h). Similar to the preceding in the shape, but much lighter blue, the wings at the base above dirty brownish grey, the disc almost without small black spots. ♀ unknown. Ecuador and Peru. Rare.

L. thara Hew. (♀ = *melia* Bat.) (137 g, h). ♂ blue, with rows of black spots, the base of the wings and the inner marginal part of the hindwing dirty yellowish-brown. quite different, whitish-yellow with black macular bands, the disc of the forewing like a band bone-white. GODMAN separates the Guiana-form as *nomia* from the (typical) Amazon-form. But 2 ♂♂ of my collection from Surinam deviate from each other more than from a Humayta-specimen. The ♀♀ from the Amazon are somewhat yellower than the figured ♀ from Cayenne, which belongs perhaps to GODMAN'S *nomia*; **martialis** Fldr. is presumably only a ♀-form from Surinam.

L. emylius Cr. (♂ = *crispus* Cr.) (137 f). ♂ vermilion with a black apical part and costal-marginal part of the wings, under surface silvery bluish-white; disc of the wings with blackish dots. The ♀ quite different, above dark-brown with an ochreous yellow oblique band of the forewing; before the apex and border small white spots. Guiana, Amazon. — **emyliana** Stich. (= *emylius* Stgr.) from Peru, Ecuador and the Amazon which I do not know is said to be larger and to have in the male increased and deeper red. Of my Peruvian specimens all the ♂♂ exhibit a lighter red which is more interspersed with black, the ♀♀ have a more irregular oblique band on a lighter ground-colour: = **crispinella** Stich. (137 f as *crispinellus*).

L. cilissa Hew. (137 f). ♂ quite similar to the preceding, but the light vermilion is replaced by orange red. The ♀♀ are quite wax-coloured with a broad dark brown margin of the forewing and a narrower dark margin of the hindwing. From Nicaragua to Colombia. Typical ♀♀ only have a border as fine as a line, the fringes of the hindwing being brown. In specimens from Costa Rica, as we figure them, the border of the hindwing is broadly brown.

L. asteria Stich., unknown to me, is placed between *cilissa* and *emylius*; ♂ above red-brown, the costa, the apical part as far as the cell-end, and the border broadly blackish-brown. In front of the apex 4 or 5 white

dots, the second being the largest. In the cell 2 or 3 sometimes indistinct transverse streaks, behind the cell 4 black strigiform spots. Hindwing with a white costal area, below it 3 rows of black strigiform spots, each of the two proximal ones with 2, the distal one with 6 or 7 spots, the latter row curved like an S. Colombia.

luciana. **L. luciana** F. (= *nepia* Ww.) (137 e). Copper-brown; costa, apical part of the forewing and distal margin of all the wings darker brown; under surface bluish-white with a dark shade in the apical area of the forewing. All the wings above and beneath finely dotted in black. ♀ has broader wings and is somewhat darker than the ♂. Panama, Venezuela. — **pseudocrispus** Ww. (= *crispus* Cr.) (137 e) has the apical part of the forewing shaded somewhat darker and more distinctly defined towards the copper-red; hardly deserves a denomination. Guiana to Bolivia; we figure a specimen from Para, in order to show the slight difference. Not rare near Bahia. — **concinna** Stch. from the Rio San Juan in Colombia is said to be distinguished by a broader dark border of the hindwing in the ♂♂ and quite dark hindwings of the ♀♀. — **nepioides** Btlr. (= *luciana* Hbn., *melanogyra* Bat.) (137 e), may be a distinct species, or may be only a district-form, from South Guiana and the Amazon, has the copper-red more fiery and the darkened parts of the wings distinctly defined towards this colour. Common.

telephus. **L. telephus** Cr. (= *alphaea* Hbn., *timandra* Ww.) (138 f). ♂ forewings black with some dispersed white vitreous dots, hindwings orange-yellow with a broad black border. Under surface blackish, the hindwings speckled bluish-grey. The ♀ has the vitreous dots and the under surface like the ♂, but it is above yellowish-brown, with a dark apical part of the forewing and a black-dotted disc. The species varies with every habitat. The couple figured by me originates from Paramba. Surinam-♀♀ are of a much brighter bean-yellow colour and have smaller vitreous dots than the figured one, while the ♂♂ from there have a darker yellow of the hindwings. There is a very interesting ♂ with quite black hindwings being only in the centre narrowly red-yellow, but with black spots in the orange part, like in the ♀, in the Paris Museum. Near St. Jean du Maroni (French Guiana) the ♂ exhibits yet a narrow orange band parting the black distal marginal band of the hindwing from the direction of the proximal margin. In Colombian ♀♀, being above very light ochre-yellow, only the apical part is distinctly defined black; in a ♀ the patria of which is not stated, in FASSIS collection, the distal margin of both wings is also broadly black, the proximal half of the wings, however, fox-coloured. As there are often different forms flying near each other, they are not to be regarded as subspecies. — A genus of its own (*Elaphrotis* Stch.) has been established for the species itself; but the habitus and particularly the under surface exhibit its alliance to the *emylus*-group of *Lemonias*. We must remark yet that the abdomen is always yellow, not brown as on the figure.

lyncestes. **L. lyncestes** Hew. Size and under surface almost exactly like in the preceding, but the upper surface quite dark-brown with black dashes, only the border is broadly red-brown, containing a series of white, proximally black dots. Guiana, Brazil; according to HEWITSON's figure the black marginal dots exhibit a white exterior which is absent in specimens I captured in South Brazil. Rarer than the preceding species.

bolena. **L. bolena** Btlr. (= *xanthobrunnea* Warr.) (138 k). Of a bright yellow, the base of the wings, a broad apical band of the forewing, the apex and anal angle of the hindwing resembling the colour of the trunk of a tree. Beneath dark-yellow on light-yellow, marked with dashes like the preceding species. South Brazil and Paraguay. Forms a transition to the genus *Echenais* which is not distinctly separable from *Lemonias*. The shape of the broad apical spot seems to be different at every habitat. In specimens from São Paulo it is the narrowest, similarly in Paraguay-specimens, in specimens from Espiritu Santo it is the broadest, in those from Rio Grande do Sul its lower part does not project so arcuately towards the base. Single and not common; flies in day-time and likes to rest on the trunks of trees.

85. Genus: **Echenais** Hbn.

Most of the species of this genus, the characteristics of which are still somewhat obscure and whose species vary in every district, have in the male sex the apical part of the hindwing white which gives a peculiar appearance to the butterfly particularly on the wing, as if it was hurt or wiped off behind. They rest in a Geometrid-like attitude on the under surface of leaves, but they come forth at some hours of the day in order to perform their gambols on the trunks of trees. ♂ and ♀ then sit on the trunk with their wings half open and execute short, skipping flights by ascending or descending the trunks in curves. *Echenais* is as little separable from the preceding genus as from the following, and might better be regarded as a group of the *Lemonias*; thus it happens that most of the species are sometimes quoted as *Echenais*, sometimes as *Lemonias*. The head is small, the abdomen long, that of the ♂ very slender and pointed, the forewings behind very broad; the hindwings rounded. The very long and capillary antennae are carried parallel and stretched straightly forward as the *Erycinidae* are used to do. The upper surface of the wings nearly always exhibits the dots and transverse streaks of the *Lemonias*, but mostly bordered light. Most of the *Echenais*, compared with other *Erycinid*-genera, are common butterflies.

tinea. **E. tinea** Bat. (142 g). The smallest species; by the speckled fringes it reminds us of a small *Calydna* as which it was also described. Dark brownish-grey; the black punctiform streaks of a dull lighter shade. Guiana and East Brazil, to the south as far as Matto Grosso; not rare.

E. eudocia *G. & S.* from Mexico resembles *tinea*, but it is often still somewhat smaller and darker, *eudocia*, quite unicolorous, with black markings, the light spotted margins scarcely appreciable, the dark fringes of the forewings at 3 places interrupted by white.

E. lampros *Bat.* is a little larger than the preceding, recognizable by the more violettish-brown *lampros*, colour of the forewings and the entirely violettish-blue hindwings of the ♂. From Teffé on the Amazon.

E. leucophaea *Hbn.* (138 i) dirty dark yellowish-brown, the upper surface copiously decorated with *leucophaea*, punctiform streaks, in front of the border of the forewing rows of black spots; there are mostly 2 of them, but the submarginal spots may also be single; such a ♀ was likewise figured, but erroneously termed *tinea*. Brazil, in some districts common; it approximates the following species.

E. aristus *Stoll* (138 f). CRAMERS figure is not distinct, but it seems to represent the most common *aristus*, species in Surinam, which we figure. Forewings almost like in *tinea*, dark, indistinctly marked in black, in front of the border a lighter line being particularly distinct in the ♀. Hindwings posteriorly white; this white colour may be narrower than on our figure (= *aristus*-♀ *E. Sh.*, *erecta* *Stich.*).

E. hübneri *Btlr.* (138 f), according to STICHEL unlike the preceding, has blue-marked (ringed) fore- *hübneri*, wings and the ♂ exhibits the greater half of the hindwing white; Amazon. — In *sordida* *Btlr.* the otherwise *sordida*, bluish marking is darkened. Amazon, Guiana. — **pauxilla** *Stich.* from Peru is said to be smaller and of intense *pauxilla*, colours.

E. alector *Btlr.* (= *violacea* *Btlr.*) (138 g, as *violacens*). Entirely like the figured form *mollis* *Btlr.*, *alector*, (138 g) except that in the ♂ the disc of the forewing above is traversed yet by a transverse macular band; in *mollis*, the ♀ of *alector* only the small white band of the forewing is somewhat darker and narrower than in the figured of *mollis*. — **glaucobithris** *Stich.* is said to be a „transition“ of the two, „but without the white hinder-marginal *glaucobithris*, diffuse spot of the forewing“. The species, moreover, greatly varies, particularly in the intensity and extent of the violettish-blue colour of the ♂ upper surface and in the shape of the small white band of the forewing in the ♀. From the Amazon to Bolivia, mostly common; in *asemna* *Stich.* the violet is almost entirely absent *asemna*, on the upper surface.

E. leucocyana *Hbn.-G.* This common species from Guiana and the Amazon forms the intermediary *leucocyana*, between the two preceding species: in the ♂ the lower half of the hindwing is white, in the ♀ not. This form differs from *alector*-♂ by its smaller size, more brownish forewings and by scarcely half of the hindwing being white, not as in *alector* the greatest part; the ♀ resembles a *leucophaea*-♀, but it is lighter brown.

E. hemileuca *Bat.* Like the preceding, but with narrower wings, lighter greyish-brown, and only the *hemileuca*, lower part of the hindwing of the ♂ white. The transition-area from brown to the white colour is tinged bluish. It is said to occur beside *leucocyana* in Guiana; it is presumably only a local deviation from the preceding. — STICHEL denominates another side-form from the Amazon **epixanthe** the hindwings of which are brown, like *epixanthe*, the forewings marked in violet.

E. aminias *Hew.* (138 f, as *alector*). Immediately recognizable by the forewing and hindwing being *aminias*, of the same design. A violet median band runs broadly through both the wings, being finely dotted and streaked in black. We figure the species from Venezuela, in which the violet is somewhat clearer, the black spotting of the median band somewhat scarcer than in the type from the Amazon. — From this, on the other hand, the form figured as „*catenifera*“ (138 h) differs; it is darker than the figure of *aminias* with HEWITSON, the violet colour very dim, the animal itself larger. The comparison with the type, however, resulted in these differences being insignificant, for which reason the name chosen in the table (*catenifera*) is better not introduced, but replaced by *aminias*.

E. balista *Hew.* (142 f). Dark-brown with black, sparse punctiform streaks and a lighter, black-dotted *balista*, margin. Beneath greyish-brown, the dotting in the disc more copious, the dots in front of the border with lighter rings around them. Upper Amazon, Ecuador.

E. argiella *Bat.* is known to me only from the author's description; apparently exactly like the *argiella*, preceding, also of the same size, but also above more copiously spotted; instead of the light, black-dotted marginal band, a series of light, dark-centred rings stands in front of the border. South Brazil.

E. sejuncta *Stich.* Unknown to me; it is said to originate from Neu-Freyburg and Rio, allied to *hübneri*, *sejuncta*, smaller, forewings relatively shorter. ♂ above greyish-brown, faintly tinged in a rusty red, towards the margin lighter and redder, spotted like the allied species. Forewings beneath greyish-brown, the spots surrounded by a light tinge, the median row only distally shaded in white; hindwings similarly spotted, the spots in the median area placed together to a zigzag-line. ♀ above somewhat lighter greyish-brown, the marking as in the ♂, forewings beneath very much powdered with white. Fringes greyish-brown.

E. malea *Schs.* is similar, but it differs by the hindwings of the ♂ being white in the lower half, and *malea*, by spots above, in the middle of the forewing, forming a dark nebulous band. Panama to Rio de Janeiro.

- densemacu-*
lata. **E. densemaculata** Hew. (= *debilis* G. & S.) (138 k). Above dark yellowish-brown, speckled ochreous, with brown spots encircled by ochreous ones which are connected with the distal margin. Beneath like above but paler. ♀ like the ♂. Apparently rare, but wide-spread; from Central America to Ecuador.
- zerna.* **E. zerna** Hew. (142 h). The figured specimen originates from Santos. Recognizable by the upper surface being marked greyish-green. Under surface bluish-white with black dots, forewing in the apical part with grey nebulous spots. Very local, but not very rare at its habitats. Brazil, Bolivia; from the latter country also the form *luteonaevia* Stich., with more white markings, hindwing with an ochreous-yellow marginal zone.
- luteonaevia.*
- glauc.* **E. glauca** G. & S. (138 k) from Costa Rica is much more brightly marked in light blue, only the apical part of the forewing and 3 rows of small dashes arranged to transverse bands are black. Rare.
- curulis.* **E. curulis** Hew. (142 h). Very pointed wings, at once recognizable by the upper surface of a bright metallic sky-blue lustre, the colour of which almost comes near the splendour of *Mesosemia croesus*. STICHEL doubts whether *E. melitta* Thm., with a darker apical part of the forewing, is to be placed here. Bolivia (Ecuador). The figured ♂ from the Rio Songo.
- lains.* **E. lains** G. & S. resembles on the whole a small ♂ of *Nymphidium ethelinda*, the head, thorax, forewing and the costal part of the hindwing are chestnut-brown, the rest of the hindwings is yellowish-white. Size of the *pulcherrima*. I only know the ♂ in the Coll. GODMAN. Guatemala.
- pulcherrima.* **E. pulcherrima** Btlr. (140 c). Rather similar to *penthea* in both sexes, but in the ♂ the white of the hindwing passes over into the proximal margin of the forewing, in the ♀ the whitish oblique band of the forewing does not terminate before the proximal margin, but turns angularly round on the lower median vein and is irregularly continued on the hindwing. Amazon. — **comparata** Stich. from Peru is more dark brown than red-brown, and the white spot at the proximal margin of the forewing is larger. East Peru. Common.
- comparata.*
- lilina.* **E. lilina** Btlr. (140 c). Forewing blue, with black spots, a large spot behind the middle of the costa and the proximal-marginal area white. Hindwings, except the dark-grey base, quite snow-white. Mexico to Panama. Our figure according to a ♂ from Costa Rica.
- icterica.* **E. icterica** G. & S. (140 d). Forewings yellowish-brown, some spots round the proximal margin yellowish-white. Hindwings dull yellowish-white with a brown base. Panama. Rare.
- penthea.* **E. penthea** Cr. (138 h). ♂ red-brown, with blackish spots, the lower half of the hindwing white with small blackish spots at the apex and anal angle. ♀ dark-brown with a whitish, irregular oblique band of the forewing and a submarginal row of eye-spots of the hindwing. — Typical *penthea* come from Guiana and the eastern coast of Brazil, they are rather small, the ♀♀ above with traces at most of yellowish-red. — **auseris** Hew., from the Middle Amazon, are larger, the ♀♀ more brightly coloured, in front of the row of eye-spots on the hindwing a distinct red colouring. — **penthides** Stich. (= *penthea* Stgr.) (138 h, i) is still larger, the band of the forewing of the ♀ is broad at the costa, the wings with bright red markings; from the western parts of South America. — **nitelina** Stich., according to 1 ♀ from the Yurimaguas, with a triangularly shaped band-spot of the forewing. — Of **echion** Stich., like the type from Guiana, the ♂ is darker brown, and a series of spots runs through the centre of the hindwing. In the ♀ the white band of the forewing is losing itself from the margin in a downward line. — **nilios** Stich. (138 i) which I figure according to specimens from the Itaituba (Amazon) shows in the ♂ the lower, otherwise white part of the hindwings almost entirely covered with brown arcuate bands, and in the ♀ the whitish band of the forewing is greatly narrowed. — At some places very common.
- nitelina.*
- echion.*
- nilios.*
- annulifera.* **E. annulifera** Godm. (138 h). The ♂ has about the ground-colour of the ♀ of the preceding species, more dark greyish-brown than red-brown. In the hindwing the marginal part is broad white. The basal halves of the wings with thick, mostly round, light-ringed eye-spots. Only the ♂ is before me, from the Rio Mapiri; reported also from Guiana.
- micator.* **E. micator** Sch. (138 h). Like the preceding allied to *alector*; twice as large as *annulifera*, the basal halves of the wings spotted like in the latter, but the forewing with a broader curved white median band, the hindwings entirely white, with the exception perhaps of the basal third. Under surface like the upper, duller, in front of the border of the hindwing grey nebulous spots. From the Rio Pachitea in Peru. The ♀ is not before me.
- galena.* **E. galena** Bat. (138 k). Above red-brown, the basal half with scarce dashes and bounded off from the purely red-brown distal part of the wings by a chain of such dashes. Beneath the black dots are more numerous and the whole proximal part of the wings is covered with small white scales, as if with powder. (The 2nd figure in the row t. 138 k is taken from beneath). Guiana and Western Amazon (Itaituba); local, but not rare.
- scut.* **E. senta** Hew. (138 i). On the red-brown wings there are alternating darker and lighter irregular bands. Before the apex of the forewing are two small whitish spots above each other, at the costa of the hindwing 2 next to each other. Beneath the boundaries between the lighter and darker bands are marked black. The figured specimen collected by BATES contains only the statement: „Amazon“.

E. borsippa Hew. from the Amazon is bright orange-red, almost miniate; the ♂ has a blackish-brown *borsippa*, apical part of the forewing and from the costa of the hindwing there extend the beginnings of black bands ending, however, incompletely in the centre of the wing. The under surface exhibits bluish-grey bands alternating with reddish-grey ones.

E. charessa Stich. is established according to a ♂ from the Rio Juruá. Small (12 mm); shape of the *charessa*, preceding, forewings red-brown, with black spots, similar to *pentheia*; in front of the border a series of black, oblong, small spots being proximally bordered in light. Inner marginal area grey as far as the submedian. Hindwings white, costal area and apex greyish-brown, at the border a fine black line, and in front of it small black spots. Unknown to me.

E. borsippina Btlr. A small species; only the ♀ known. On a dark-brown ground the forewings exhibit *borsippina*, 3 incomplete red-yellow macular bands before, in and behind the centre and a complete stripe before the border. Hindwings light yellow, costal part and apex brown, in front of the border some small black spots. From the Rio Tapajoz. Is not before me.

E. elpinice Godm. (♂ 142 f, ♀ 138 g). As the ♂ which was hitherto unknown and which I therefore *elpinice*, likewise figure, shows, a real *Echenais*. Under surface quite similar to that of *alector*-♂. ♀ with obtuser wings, the ring-marking not so distinct. Bolivia, Colombia; the figured ♂ from the Rio Songo (Coll. FASSL).

E. aemulius F. (= *geris* Dbl., *hemixanthe* Fldr.) (138 g). Similar to the preceding species, larger, *aemulius*, and recognizable by the broad orange distal band of the hindwings passing over to the anal angle of the forewing. South Brazil. In Rio temporally common, but local (e. g. near Botafogo). — **adelina** Btlr. (138 g) from *adelina*, Costa Rica to Ecuador has the hindwings, except the base, pale yellow which colour extends far on to the forewing.

86. Genus: **Calliona** Bat.

This genus is as little separable from *Lemonias* as the preceding. Its resemblance with *Aricoris* accepted by BUTLER only refers to the exterior. The ♂♂ do not resemble much the *Lemonias* owing to the large white discal spots on both wings, but anatomically there is hardly any difference. The *Calliona* are of a still more slender structure than most of the *Lemonias*, the palpi project greatly also in the ♂, the antennae are scarcely thickened at the ends; the ♂♂ with white discal orbs, the ♀♀, as far as is known, with a yellow oblique band of the forewing. The butterflies are apparently very rare.

C. irene Ww. (138 a). On each of the 4 black wings of the ♂ a white, roundish disc, the basal part *irene*, of the hindwings scarlet. Under surface greyish-brown with 4 white discs as above; in the basal part of the wings dark transverse bands. The ♀ looks entirely different, resembling somewhat *Mesene sagaris*-♀ (134 i), but the ground-colour is lighter brown and makes the same transverse streaks the ♂ also has appear in a dull shade Lower Amazon: Para, Humayta.

C. siaka Hew. (138 a). ♂ similar to *irene*, larger, hindwings along the costa red, along the border blue. *siaka*. Beneath in the basal part of the hindwings scarce dark small spots. I do not know the ♀. From Maipures on the Orinoco and Amazon.

C. latona Hew. (138 a). The ♂ has the forewings similar to the preceding, but it is smaller and its *latona*, hindwings have not a white, but a scarlet inner-marginal stripe. From the Amazon. — In *delia* Stich. the white *delia*, discal spot of the forewing is much smaller, the whole hindwing, except narrow margins, red and beneath there are no dark transverse streaks. Known to me only from STICHEL's figure and description; from Venezuela.

87. Genus: **Corachia** Schs.

This genus was based on a single ♀ which greatly approximates some ♀♀ of *Lemonias*. It has, however, a more strongly curved margin of the forewings and short, knobbed antennae. The upper median vein rises close at the lower cell-angle, the lower radial comes out of this, the cell-end vein is proximally convex, somewhat oblique. The hindwings are long, almost as long as the forewings, whereby nearly the exterior of an Indian *Gerydus* (*Allotinus*) is created.

C. leucoplaga Schs. (= *tablazonis* Strd.). ♀ quite similar to the ♀ of *Lemonias argenissa* (137 i), but *leucoplaga*, the white band of the forewing is broader with bulging margins and traverses the wing transversely, not obliquely. In the ♂ this band of the forewing is replaced by a faded, grey, costally parted discus-spot. Costa Rica, certainly rare.

88. Genus: **Nymphidium** F.

The uniformity of the veins argues against the branching-off of further genera such as *Peplia* Hbn., *Nymula* Bsd., etc. which have recently been again based upon differences in the palpi and the male exterior genitals. If the well done figures in the „Genera Insectorum“ are correct, I cannot find any essential difference between the palpi of *Peplia* and *Nymula*, and the clasping-organs vary also considerably in different undoubted *Nymphidium*. In the veins there is no difference. Some *Nymphidium* are obviously secondarily transformed

by mimicry, otherwise the almost exclusive colours are brown and white either of which being now and then preponderant. The wings have a normal shape without indentations, tail-appendages, lobing or coiling. The larva is known of but 1 species, shaped like a wood-louse, hunched, green with a yellow lateral streak, the neck-organ out of a transverse row of green spikes or bristles. It has a guard of ants. Papa green, fastened by a belt-like thread. The butterflies rest on the under surface of leaves and are chased up by beating the bushes, whereupon they fly like Geometrids for some paces, in order to hide themselves again. The swarming-time seems to be dawn, or the early morning, but I came across the ♀♀ yet in the sunshine of the morning on blossoms. They are easily taken and fly low.

- titia*. **N. titia** Cr. (= *tytia* F., *gnosis* Bsd., *eroe* Hew., *lytia* Kaye) (140 b). ♂ dark purple-brown with a small white spot below the costa of the forewing and a light-brown, blurred distal band of the hindwing. ♀ dark sepia-brown with 3 white spots of the forewing (in the disc, below the costa and before the anal angle), the hindwing with a white distal band. Under surface of both sexes similarly marked, but in the ♂ at the margin slightly brightened up, in the ♀ very much white-speckled. Guiana, near Cayenne not rare. — **arctos** Hew. (140 a, b) is larger, the ♂ with a very faint brightening before the border of the hindwing; the ♀ also lighter before the border of the hindwing, but without a real white band. Amazon. — ♀♀ from Teffé form the intermediary between the two forms; they have a very narrow white band. — ♂♂ from Ecuador and Peru are quite dark brown, without the brightening before the border of the hindwings, the small, white subcostal spot of the forewing being larger (= **ariadne** Stch.)
- orestes*. **N. orestes** Cr. (140 c). The butterfly occurs in 2 forms which, however, are not definable according to patriae. The typical form has above quite unicolorously dark red-brown ♂♂ being faintly dark-speckled, looking almost like the ♂♂ of *arctos* in which the brightenings below the costa and before the border of the hindwing are absent; the ♀ has an ochreous-yellow band of the forewing. — The second form, **arche** Hew. (140 b) has above an irregular transverse band being in the ♂ only slightly indicated, in the ♀ composed of large white spots. Guiana and the Amazon, common, also the ♀♀; according to STICHEL, also in Ecuador.
- candace*. **N. candace** Drc. Unknown to me in nature, mentioned from Rio de Janeiro. Size of the preceding, but the hindwings larger, rounder, the border not bevelled as in the preceding species. Above of a red-brown colouring without markings, beneath only faint traces of the numerous ring-marking of the proximal half. — Unless the patria be confounded, it must be very rare.
- sorana*. **N. sorana** Stoll approximates *orestes* and originates from Guiana; above dark red-brown, the oblique band of the forewing yolk-coloured, uniform.
- abaris*. **N. abaris** Cr. (= *tenes* Dbl., *sperthias* Fldr.) (140 c). ♂ above velvety brown, at the border, sometimes also across the centre, copper-red. Below the costa a small light spot may stand as in our figure, but it may also be absent altogether. The dark-brown ♀, however, always has this spot, and besides the anal angle of the forewing and the border of the hindwing is bone-yellow or marked thus. Guiana and Amazon, very common; in Trinidad apparently rare.
- phylleus*. **N. phylleus** Cr. (= *phyleus* Mschl., *phylacis* Godt.) (140 a as *phyleus*). ♂ with a red-brown forewing with fox-coloured bands and rings, and a fox-coloured hindwing exhibiting black antemarginal dots, a dark-brown base and a similar median band. Below the costa a bone-coloured spot. The ♀ is dark-brown, with a broad bone-white band of the forewing and disc of the hindwing and a similar stripe in front of the border. The ♀ varies extremely; the white bands are of a different shape at every habitat; we figure an aberration in which all the whitish bands are darkened by a brown scaling (artificial production?). — **apame** Hew. (= *magnifica* Stch.) scarcely differs in the male from typical *phylleus* except the red bands being narrower; in the ♀, however, the white is greatly narrowed on both wings; from the Amazon. — **praeclara** Bat. (140 a), on the contrary, has the bone-yellow colour increased at the cost of the dark-brown ground-colour; from Guiana. The species is not common.
- licinias*. **N. licinias** Stgr. (142 f). Dark-brown, in the marginal area red, in the basal area with black markings; both the wings are traversed by a joint band bent proximally towards the costa of the forewing, being in the ♂ of a bright golden yellow, in the ♀ lighter, more brownish-yellow. From the Rio San Juan in Colombia. STAUDINGERS figure of a ♂ which we copy corresponds well with a specimen in GODMANS collection. Apparently very rare.
- dorilis*. **N. dorilis** Bat. resembles *licinias* to which it belongs according to STICHEL; but the red-yellow median area has here the shape of the white band of *calyce* (139 e).
- nymphidioides*. **N. nymphidioides** Btlr. (= *labdacus* G. & S.) (141 c). Size of *phylleus*; ♂ with light small median spots in the disc of the red-brown forewing. ♀ white, the forewings with a brown border and a brown basal part, in the latter white, dark-pupilled rings. Central America, rare.
- ethelinda*. **N. ethelinda** Hew. (139 i). ♂ chestnut-brown, forewings almost without any markings; hindwing except the basal third and the apex yellowish-white. ♀ similar to that of the preceding species, but at the costa of the forewing a broad, at the border of the hindwing an interrupted, brown stripe. Central and South Brazil. Rare.
- nycteus*. **N. nycteus** G. & S. (141 c). ♂ similar to that of the preceding, but the hindwing, except the brown apex, snow-white, and this colour also passes over to the forewing before its anal angle. ♀ white, through the whole forewing runs a broad, brown, black-marked longitudinal band from the base to the border above the anal angle. Central America.

N. grande *G. & S.* (139 i). The largest species of the genus. A broad oval white or yellow band *grande*, begins behind the cell of the forewing and ends round before the inner margin of the hindwing. In front of the border a double row of small white spots, before it a red stripe. Beneath like above, somewhat duller, the small marginal spots larger. There occur ♀♀ with yellow as well as white bands. Colombia. Rare.

N. victrix *Rebel* (139 h). Conspicuous for the hindwings of the ♂ being pointed in the anal part and *victrix*, provided with a straightly cut off border. Dark-brown with a white, rather narrow, joint median band of the wings; behind it a small, curved, red-yellow band, behind this, before the border, an irregular white stripe. Rio de Janeiro, but presumably scarcely near the town, but farther in the mountains and rare. Is said to occur also in the Amazon district (?). The species seems to be transformed by mimicry.

N. phliasus *Cr.* (= *hewitsoni Rebel*) (139 h). Likewise subject to mimicry, reproducing an *Adelpha phliasus*, from its surroundings (*A. phliassa*). The orange spot behind the cell of the forewing projecting in a tooth towards the border passes over into the white median band without any separation. The width and shape of the band varies somewhat according to the habitat. Guiana. Rare.

N. maravalica *sp. nov.* (139 h, i). Only in the ♀ the *Adelpha*-resemblance is distinctly visible by a *maravalica*, separated orange spot standing before the white, though orange-ending median band at the costa of the forewing; it imitates the *Adelpha*-form *duceleia Fruhst.* The ♂ has the shape of the bands of *phillone*, but the upper tip of the band is faintly tinged orange. Isle of Trinidad, presumably also opposite in Venezuela.

N. enimanga *sp. nov.* (139 g as *paulistina*). Without the orange spot before the apex of the forewing; *enimanga*, the white median band is here so much broader that it covers the whole disc of the forewing and the whole hindwing except the border and base. The under surface is all white except a spotted costal stripe of the forewings and the moderately broad brown distal margin of both wings. Paraguay; the species is apparently not common *).

N. phillone *Godt.* (= *phliasus Rebel*) (139 g, h, as *paulistina*). At once discernible from the preceding group by the round border of the hindwing and a rusty-red tinge of the collar and sheaths (what is unfortunately not marked in the figure of the ♀. The white band of medium width varies at every habitat. In specimens before me from Neu-Freyburg the band ends obtusely in front (our ♀-figure), in the neighbouring Rio de Janeiro pointed (♂-figure). In specimens from Theresopolis (or San Pedro?) it is said to be narrower (= *pedronia Stich.*) and in specimens from São Paulo (= **paulistina** *Stich.* 142 g, not 139 g, h, as *phillone*) still *paulistina*, narrower, as narrow as in *victrix*. (The animal denoted as *paulistina* on t. 139 g is another species — *enimanga* — and does not belong to *phillone* *Godt.*, but it is allied to *victrix*, *phliasus* and *maravalica*). — Not rare.

N. velabrum *G. & S.* (139 i). Above the upper end of the white band, being common to both wings, *velabrum*, we notice an orange-yellow preapical spot. This creates the impression of an *Adelpha iphicleola* from Central America. Panama.

N. calyce *Fldr.* (139 d, e, as *calice*). Both sexes brown with black, light-bordered spots before the *calyce*, margin. The moderately broad median band ends in the ♂ above taperingly, in the ♀ broad; the latter exhibits in typical specimens before the border a red-brown band being on both sides shaded with dark-brown. — In the form *mesoleucum* *Bates* described from Baranquilla in Colombia this red-brown band is absent, but the forewings exhibit a white submarginal stripe instead. — From the northern coast of South America, inclusive of Trinidad, to the south as far as South Brazil nearly everywhere common. The butterfly, being an Erycinid, is an uncommonly good flyer which, however, must nevertheless in day-time be invariably beaten out of the bushes skirting the forest-roads. It varies but little in its immense range; in the figured couple (from Rio) the bordering of the white band is almost smooth, in specimens from Cuyaba the inner (proximal) border of the band is somewhat more dentate etc. From Peru there are specimens of both sexes before me, with a pale yellow median band; in a specimen taken in Peru at 2000 m, however, the band is purely white. — **brennus** *brennus*, *Stich.* I cannot distinguish from typical *calyce* neither regarding the description nor according to the ♂ before me having been denoted with this i. l.-name by *STAUDINGER*; of **manius** *Stich.* the ♀ is said to resemble more *manius*, that of *mycone*.

N. mycone *Hew.* (139 e) is, according to *STICHEL*, only a deviating form of the preceding species, *mycone*. The border of the forewing is more rounded, the hindwing of the ♂ somewhat more reduced in the anal part. ♂ above quite red-brown, without the white median band; the ♀ exhibits the latter and, therefore, greatly resembles that of *calyce*, but the band of the forewing is not so round above, but more obliquely cut off. Mexico and Central America as far as Colombia, where also *calyce* occurs.

N. gela *Hew.* (139 f). Very closely allied to *calyce* in the shape and marking, but the band pale yellow, *gela*. Typical specimens originate from the lower Amazon (Santarem); they are represented by our ♀-figure, exhibiting a red-brown base of the wings and a red-brown transverse stripe between the white band and the border of the wings. Specimens from French Guiana have a more blackish-brown base of the wings and, according to the habitat, they are large with a broad median band (opposite the Devil's Island) or small and with narrow bands (Cayenne). Common.

*) According to *STICHEL*, the figure of our *phillone* 139 g, h represents his *paulistina*. Before me, however, are the types of *STICHEL*'s *paulistina* (from the Coll. *RÖBER*) which I figure (142 g). By *STICHEL*'s quotation „*Hew.* 4, fig. 29” in the typical *phillone* *Godt.* we recognize in *paulistina* *Stich.* a very slightly narrower white-banded deviation which cannot be combined with the quite differently shaped *victrix* *Rebel*.

- pelops*. **N. pelops** F. (= *pittheus* Hfegg.) (139 g). Spelled „*pelope*“ by HÜBNER; it has a much broader median band covering the whole hindwing except the brown border; recognizable by a trapeziform projection of the brown costal band of the forewing. In specimens from Venezuela (Suapure) this projection is broad and has bevelled sides (= *cavifascia* Btlr.), in specimens from Fonte Boa (Amazon) the corners of it are blunted off (♀-figure); Para-specimens exhibit it shortened and almost unspotted, copper-red margins of the wings; in those from Medina (Colombia) the margin of the wings is blackish-brown, nearly without any red etc. — Not rare.
- agle*. **N. agle** Hew. (139 g). Very closely allied to the preceding, but the dark border of the forewing with a red filling, not with red rings. Instead of the trapezoid projection of *pelops* we notice a small comma-spot at the cell-end, projecting into the white of the disc. Range as in *pelops*, Guiana and North Brazil. The distal band may be broader or narrower (= *furva* Stich.) and with more intense (= *quinoni* Weeks) or less intense (*menalcidas* (= *dirca* Stich.) markings. — Common. — **menalcidas** form. nov. (139 f, as *menalcus*) is larger, darker yellow, the margin above black, the marking above extinct, the dark marginal spots beneath smaller, more distinct; from the Kouron River, opposite the Devil's Island.
- chaonia*. **N. chaonia** Hew. (140 a, misprinted into *chionea*) is larger, yellowish-white and has a white crescent in the dark apex of the forewing, a white line embedded in the marginal band of the hindwing. Amazon to Bolivia; on the Rio Songo the subapical white spot is greatly reduced.
- ochra*. **N. ochra** Bat. (139 f) from Bolivia and the Upper Amazon entirely resembles *agle*, but the margin of the wing is black, not redbrown and is traversed on the forewing by a single, on the hindwing by a double, pale-yellow line connected by rungs. — In **sicyon** G. & S. from Central America the yellow line is absent in the margin of the forewing, but in the hindwing it appears treble, not double, and without the connecting rungs. — Rarer.
- regulus*. **N. regulus** F. (= *ebusa* Dbl.) (140 e). The yellow median band is bevelled at its anterior end and does not appreciably expand towards the inner margin of the hindwing. Behind it the forewing exhibits 2 oval spots, the hindwing a stripe parallel to it. Brazil. — Specimens from the Upper Amazon and Bolivia usually have a broader median band (? = *sylvarum* Bat.), but the form varies according to the habitats. Thus both *regulus* and *sylvarum* are reported from Para, but they are still said to be „subspecies“ of one species.
- lamis*. **N. lamis** Stoll (139 c, d). Very similar to *calyce*, but larger, the ♀ with broader bands, the band of the forewing is mostly also more irregularly defined. Easily discernible by the longer and slender palpi of the ♂ (whereas in *calyce* only the ♀ has long palpi) and by the abdomen which in *calyce* appears only white-pruinous at the sides and beneath, being also above white in *lamis*. Mexico to the Amazon, varying greatly. — **azan** Hew. (= *australis* Fldr.) (139 d) is the southern form from South Brazil to the north as far as Bahia, common in Santos where I collected the ♀♀ on blossoming bushes. From those of typical *lamis* they differ by the white band being nearly twice as broad. Among these ♀♀ there flew uncommonly large ♂♂ of *calyce* one of which is by mistake figured as *azan*-♂ (t. 139 d, 2 nd fig.), as I had taken it together with *azan*-♀♀ and, therefore, regarded as the ♂ belonging thereto. The ♀♀ do not only vary regarding the boundary-line of the white band; some have the brown margin of the hindwings filled with red, some not; these, however, are no geographical differences of subspecies. — **completa** Lathy (139 d) are ♀♀ from Peru with a single, medium-broad, regularly bent band. — **molpe** Hbn. (139 b, c) is presumably nothing but a small form of *lamis* occurring from Mexico as far as the Amazon, being mostly very common and living more in the open country than in densely wooded forests. — **caucana** Stich. has only the size of *molpe*, but an especially broad white band. Described from Colombia. — **ipsea** G. & S. are *molpe* from Nicaragua in which the median area is yellowish instead of white and rounded at its upper end. There exist, however, all the transitions to it, so that *ipsea* is hardly maintainable as a distinct subspecies.
- azanoides*. **N. azanoides** Btlr. (139 c). The ♂ entirely resembles that of *lamis*, but it is blackish-brown, the white band above pointed, smoothly defined, in the anal part of the hindwing a yellowish-red band being sometimes stunted to mere traces. The ♀, however, is quite different from that of *lamis* or *azan*, the white median band not broader than in the ♂, the red band in front of the border of the hindwing mostly broad and bright, the under surface variegated. Central America (Costa Rica), Colombia to Bolivia and Peru. In specimens from the two latter countries the bossy spots at the border are larger, higher, and the yellowish-red of the hindwing is reduced in the ♀, in the ♂ it has entirely disappeared above. Not rare.
- lisimon*. **N. lisimon** Stoll (139 b). Sometimes spelled *lysimon*, or *lisimaena* or *lisimond*, resembles *azanoides*, but it is scarcely of half its size, but the marking and colouring above is almost exactly the same as there, which is the case in both sexes. Guiana. — **platea** Ww. (139 b) is a larger form with a broad, not so taperingly terminating white band and a lighter red, occurring on the Upper Amazon and in Peru, where, however, it seems to be rare, while *lisimon* is common in Guiana. — **chimboraizium** Bat., discovered by SPRUCE at 3000 ft. on the Chimborasso, is an alpine form in which the hindwings exhibit red-yellow traces only yet in the anal angle; — in *hesperium* Stich., on the contrary, the red stripe is prolonged towards the apex; from Peru. — **erythroicum** Stich. are specimens with more intensely red markings, particularly such that have several small red spots

also in the cell of the forewing, otherwise they resemble *platea*; — the same small spots occur also in **plinthobaphis** *Stich.*; but there the red band of the hindwing is also expanded almost to the border; Peru.

N. olinda *Bat.* (139 b). Quite similar to *lisimon*, but above there is no red at all, and the white oblique stripe beginning narrowly from the inner margin of the hindwing, grows more and more narrow and dim, so that it is obliterated near the centre of the hindwing. The ♀ which has already the long wings of *mantus* (140 e), exhibits a broader and above less darkened oblique band. Central America, rare. — The Colombian form, **fulminans** *Bat.* (139 b), with a considerably broader median band, is much more common.

N. nealces *Hew.* (140 d). A very rare butterfly of which I have seen but few specimens. The forewings similar to those of *baeotia* (140 d), in the hindwings, however, the whole inner-marginal part is orange. Beneath forewings likewise greatly resemble those of *baeotia*, the hindwings, however, are in the ♂ quite light-yellow with 5 brown marginal spots in front of which a narrow, small, curved brown band winds from the apex towards the anal angle which, however, it does not reach. ♀ with a broad, pale-yellow median band. Known to me only from Cayenne, from where also the figured specimen.

N. baeotia *Hew.* (140 d as *baeotica*) looks almost like a small *olinda*. The light median band is sometimes darkened by grey, varies somewhat in width and its upper end is obtuse in the ♂. The ♀ mostly has also whitish fringes of the hindwings. Guiana, Amazon. — **minuta** *Drc.* (142 h) is a form with a much broader and brightly white median band, a broad white border of the hindwing in the ♀ and an almost snow-white, scarcely black-spotted under surface of it. Before me from Matto Grosso, but also from the Chiriqui. At some places very common.

N. mantus *Cr.* (140 e). Larger than *baeotia*, similarly marked, but with a reflecting light-blue costal area of the forewing and a similar distal half of the wings; the surroundings of the white band black. — **ab. thryptica** *Stich.* (140 e) has a small rusty-yellow semi-band proceeding from the inner margin of the hindwing. From Guiana and Venezuela to Brazil. Not common.

N. omois *Hew.* (139 e). A small butterfly from the Amazon, forewing dark brown with a white, large triangle placed on the inner margin; hindwing white with a black-spotted marginal band. In front of the marginal spots runs a distinctly though irregularly defined, golden-yellow band. Rare.

N. caricae *L.* (139 a). Dark brown, with a broad white band beginning taperingly behind the cell of the forewing and terminating broadly at the inner margin of the hindwing. Costal part of the forewing with orange-red spots, in front of the border of both wings an orange-yellow band, behind it, in the brown shade of the border, whitish bows. Abdomen white. According to the habitat and even to the season, the distribution of the red-yellow and black varies considerably, as well as the size which varies between 20 and 36 mm in my specimens from Cayenne and Colombia. **ab. carmentis** *Stich.* has the white increased, being continued lacini- formly at the upper end of the median band; — in **carissima** *Stich.* the marginal band of the hindwing is without the whitish bow-streaks. Guiana and Colombia. Here and there very common.

N. acherois *Bsd.* (139 a, only the ♂). Costal and distal parts of the hindwings blackish-brown, with broad orange-red fillings. Behind the upper end of the white median band a white subapical spot. — South Brazilian specimens exhibit a narrower golden-yellow border of the hindwing; the small white subapical spot may be stunted to traces, but also so enlarged that it is confluent with the median band. These forms ought not to be denominated, but the South Brazilians were separated as **erymanthus** *Mén.* (139 a, also the figure denoted as *acherois*-♀). Guiana to South Brazil; common.

N. balbinus *Stgr.* (139 a). Typical *balbinus* differ from our specimen originating from Chuchurras (Rio Polacaza) by a still broader red band of the hindwing, which, however, has no black dots and neither passes over to the forewing. The typical *balbinus* come from Rio San Juan in Colombia; only the ♂♂ are known.

N. haematostictum *G. & S.* (= *haemostaticum* *Stich.*) (139 a) from Panama and the adjoining part of Colombia resembles a ♀ of *acherois*, but it has more white which is slightly darkened by yellowish, and only in the marginal band of the hindwing there is yet an orange-yellow filling. Rarer.

N. onaeum *Hew.* (= *blakei* *Weeks*) (139 b). White with a dark-brown marginal band; cellular part of the costal stripe with red-yellow spots, before the marginal brown in the anal part of both wings there is likewise red-yellow. Central America from Honduras to Panama, Colombia and Venezuela; apparently not common.

N. chione *Bat.* (= *stilopteris* *Btlr.*) (139 f). Snow-white, with black margins, without any red-yellow, the white discal part irregularly defined. In the black marginal band white arcuate lines. Amazon to South Brazil.

N. menalcus. Of this species there exist 8 forms. In order to preserve the denominations, we might make the following differentiations: **cachrus** *F.* (= *damon* *Hbn.*) is a large form with a pale-yellow ground-colour, a copiously marked, proximally irregularly defined, jet-black marginal band. This form being especially common in Colombia, but occurring also in the Amazon District and Guiana, is represented by our ♂-figure; the ♀ of it is figured 142 h. — The animal figured 139 f as *cachrus*-♀ already forms a transition to the typical form of **menalcus** (= *onoba* *Hew.*) a couple of which is figured 142 h, being distinguished by a proximally smoothly

- defined marginal band and a paler ground-colour, as well as a narrower dark margin; common in French Guiana.
- heliotis*. — **heliotis** *Bat.* differs considerably by the ground-colour being a pale ochreous-yellow with a brownish tinge. —
- leucidiodes*. **leucidiodes** *form. nov.* (142 i) is a pygmean form of which a series is before me from different places of Guiana and which may be the inhabitant of particularly dry habitats. —
- ascolia*. **ascolia** *Hew.* (142 k) is a large form, closely allied especially to *cachrus* and *menalcus*, recognizable by the very broad margins and a small red band in the anal part of the hindwings. —
- ascolides*. **ascolides** *Bsd.* exhibits an entirely black abdomen which in *cachrus* is whitish at the sides and beneath, partly also above; otherwise not differing from *ascolia* worth mentioning; from Central America. —
- augea*. **augea** *Drc.* (142 k) differs from *ascolia* only by a greater extent of the red band of the hindwing reaching in the ♂ almost to the apex, in the ♀ even beyond it to the forewing. Most of these forms are connected with each other by transitions and may scarcely be assumed to be subspecies. Common.
- eutrapela*. **N. eutrapela** *Bat.* may also be only a form of the preceding species. Forewing with a dark-brown costal streak, a dark-brown base and a broad brown marginal band. From the costal stripe small transverse stripes extend into the white of the wing, which projects with 2 continuations into the brown marginal band; in the latter we notice the white arcuate streaks, being also distinct in *menalcus*, in front of the marginal band at the anal angle sometimes a little red-yellow. Recognizable by the abdomen being all white on both surfaces. Lower Amazon.
- ninias*. **N. ninias** *Hew.* (140 d, as *minias*). White, without the dark costal stripe, the apical part of the forewing broadly violettish-brown, with white markings and anteriorly shaded with an ochreous yellow; hindwing with a similar marginal band. Upper Amazon. —
- medusa*. **medusa** *Drc.* (140 d) which we figure from Humayta, but which flies quite similarly also in Peru, exhibits the marginal band of the hindwing reduced to few small dark marginal spots; — and in
- galactina*. **galactina** *Stich.* there is no marginal marking whatever on the hindwings; from Cuyaba in Matto Grosso and on the Amazon. — Beside such specimens with purely white hindwings, however, there are near Cuyaba also such with a complete black, proximally undulately defined marginal band of both wings; they also have the dark basal spot along the costa of the forewing further expanded and they would then also have to be denominated: **undimargo** *form. nov.* (142 i). — Not rare.
- leucosia*. **N. leucosia** *Hbn.* (140 d). Pale yellow, at the apex and above the anal angle of the forewing as well as at 3 places of the margin of the hindwing violettish-brown, white-marked spots. The base of the wings is likewise brown. Lower Amazon: Obidos, Santarem, Para. Rarer.
- kadenii*. **N. kadenii** *Fldr.* (140 d). This species unknown to me in nature resembles an *acherois* in which the white is increased, the dark marginal band reduced and the orange stunted to a small subcostal spot. In front of the border, the marginal band is traversed by a metallic line. Venezuela. — STICHEL thinks it probable that the species belongs to the following genus.
- cyneas*. **N. cyneas** *Hew.* (139 e). Yellow with a black, unmarked margin. A mimetic copy of a homochromous *Cylopodina* together with which the animal flies in Peru and Bolivia. The figured specimen originates from the Chanchamayo and has a broader margin than Bolivians. Beneath exactly like above. — The *Nymphidium* are not mimetic and it is, therefore, not likely that this species belongs here. The compact structure and the exterior borrowed from other butterflies much rather assign the species into the following genus, and the latter is again probably rather closely allied to *Esthemopsis*, *Ithomiola* or another of the mimetic genera than to the *Nymphidium*, being similar merely in the exterior.

89. Genus: **Imelda** *Hew.*

Only 2 or 3 distinct species are reckoned hereto, but presumably also the last species enumerated among the *Nymphidium* belongs to this genus, since it certainly does not represent a genuine *Nymphidium*. KIRBY inserts the genus between *Nymphidium* and *Lucilla*, MENGEL adds it to *Zelotaea*, STICHEL places it between the (newly established) genus *Elaphrotis* (*telephus* *Cr.*) and *Astraeodes*. The species have an uncommonly small head with a narrow forehead, a globular thorax and an abdomen that does not reach the anal angle of the hindwings. The wings, of a normal shape, exhibit the cell of the hindwing comparatively very long for an *Erycinidae*; the upper median vein of the forewing branches off far before the lower cell-angle.

- mycea*. **I. mycea** *Hew.* (= *glaucosmia* ♀ *Thm.*). ♂ whitish-yellow, ♀ mostly paler; in the black margin at the apex 3 small white spots and in front of the border a yellow, lustrous line. Colombia. —
- aenetus*. **aenetus** *Hew.* (= *oenetus* *Mengel*) (128 i) has the small apical spots smaller and the metallic line in the marginal band of the hindwing bluish-grey; Bolivia and Peru. — As
- leucophryne*. **leucophryne** *Stich.* (128 i) I figure a specimen from Marcapata (Peru, 4500 ft), beside a Bolivian specimen, in order to show on what slight differences this form is based. — Not very rare.
- glaucosmia*. **I. glaucosmia** *Hew.* (128 i). Dark blue, of a metallic lustre, parallel to the border 2 or 3 black lines; recognizable by the small white subapical band of the forewing. Ecuador. — In a specimen before me from Colombia (Pacho, 2200 m, captured by FASSL) the proximal lines are straighter, the small white band traversed by strong veins, and in front of the small band there is yet a tiny costal spot. I consider this to be only a local aberration; STICHEL denominates such Colombian specimens **terpna**. — *glaucosmia* shows a homochromism with *Mesosemia*, the preceding species with certain *Terias*.

90. Genus: **Lucilla** Hew.

This genus is placed by KIRBY between *Imelda* and *Thisbe*, whereas STICHEL justly adds it to *Lymanas*. The shape of the body and wings resembles the preceding genus. As to the neurulation, the genus differs from *Imelda* particularly in the system of the subcostal veins of the forewings, and the cell of the hindwing in *Lucilla* does not reach the centre of the wing, as in *Imelda*. Only 4 forms, being closely allied to each other, are known. All the *Lucilla* are rare.

L. camissa Hew. (128 c). A true copy of a *Catagramma* of the *brome-* and *denina*-group with a large orange spot of the forewing and a blue lustrous spot of the hindwing. Ecuador. *camissa*.

L. aterra Sm. From Colombia. Differs from the figured *pomposa* Stich. (128 c) by a narrower red band of the forewing and by the rays of the hindwings which are more distinct and more sky-blue, particularly towards the margin. *pomposa*, not lying before me, is described from Peru. *asterra*, *pomposa*.

L. suberra Hew. Black, in the disc of the forewing a large, miniate disc, similar to certain *Heterocera suberra*, from the *Nelo splendens*- and *veliterna*-group, together with which the species flies in Ecuador. Very likely this homochromy, however, is only secondary, and the model of both, the *Lucilla* as well as *Nelo*, are *Actinote* from the *callianthe*-group, with which they swarm on the sands of the river-banks.

91. Genus: **Thisbe** Hbn.

The genus is so very much altered by mimicry that it is difficult to find out its real alliance. STICHEL places it between *Rodinia* and *Lemonias*; it has nothing in common with these two. STICHEL, however, has justly abolished the insertion of a *Thisbe*-species in the *Nymphidium*, which had proceeded from a mimetic mystification. The body is uncommonly strong, the head Nymphalid-like, the palpi projecting, the antennae very long, in the ♂ to $\frac{3}{4}$ of the length of the costa. The hindwings pointed at the anal angle, in *lycorias* even produced in a broad tooth. The butterflies are less rare than is the case in most of the other mimetic species.

Th. lycorias Hew. (140 f). Dark brown with a white oblique band, above and behind which there are white spots. Round the white median band are above red-yellow spots, beneath there are such only in the anal areas of both wings. Mexico and Central America. The typical form originates from Honduras and has in front of the margin of the hindwing another broad white stripe, as it is also found in all the Mexican specimens. — ab. **adelphina** G. & S. (140 f) shows this distal stripe obliterated. — **germanus** G. & S. (140 f) distributed from Colombia to Ecuador has the red spots much smaller, they are mostly also not so numerous in the cell of the forewing. — **incarum** form. nov. (140 f) from Peru, from a very dry habitat, deviates the most from the typical form; it has a lighter ground-colour, a very narrow median band, the orange spots are pale and dim, particularly the one above the anal apex of the hindwing. — *lycorias* is in some places common. *lycorias*, *adelphina*, *germanus*, *incarum*.

Th. irenea Stoll (= *belise* Stoll [♂], *belides* Stich., *atlantis* Stich.) (140 f, g). ♂ black with a white median band embedded in blue, above the upper end of which we see a small whitish oblique band. The ♀ is quite different, without any blue above at all and with a broader median band and another, second oblique spot behind the small subapical oblique band. From Guiana there generally come ♀♀ with narrower bands than from Colombia (*belides* Stich.), but these forms are not to be arranged according to patriae. We figure a narrow-banded ♀ from above, a broad-banded one from beneath. Both are from Venezuela. We can just as little assert that the Isle of Trinidad possesses a subspecies of its own (*atlantis* Stich.); the latter is said to have more blue in the distal area of the ♂-hindwing. Such specimens, however, are before me also from Suapure. Much rather Costa-Rica-specimens would have to be denominated, in which the median band of the ♂♂ exhibits only quite a narrow blue bordering. In a ♂ from „Bolivia“ the white subapical stripe is as long and broad as in ♀♀ from Surinam etc. Central America and Guiana to the Amazon and Bolivia, local but mostly common. Like the *Dynamine* (being imitated by the ♀), the butterfly mostly flies about at a hardly accessible altitude on the tops of young trees. *irenea*.

Th. molela Hew. (140 g). In the ♂ the blue median band of the forewing is not white-pupilled, but it has only at its upper end a tiny white spot. In the hindwing the white band of *irenea* is replaced by a dull, strigiform brightening which is often scarcely perceptible and grows distinct in some specimens (as the figured ♂ from the Amazon) only at the inner margin (ab. *palilis* Stich.). The ♀ resembles above that of *irenea*, but the under surface is marked quite differently, as the figures show. Not rare in Venezuela (Suapure). Guiana, Para and so on. *molela*.

92. Genus: **Anatole** Hbn.

The genus consisted only of 1 species to which 3 more were recently added as being congeneric. They are robust animals, of the structure of the *Nymphidium*, with a considerable sexual dimorphism. The veins do not exhibit any peculiarities; the 3rd subcostal vein rises with the 1st radial from the upper, the 3rd radial with the 1st median from the lower angle of the cell of the forewing. The species are common at their habitats.

glaphyra. **A. glaphyra** Ww. (140 h) greatly approximates the *Thisbe*, also in the shape of the wings (preanal tooth of the hindwing) and in the shape and marking of the ♀, so that it might better be added to *Th. molela*. ♂ similar to the ♀, the latter like *molela*, but the wings from the white band to the base of the wings bluish-grey. Under surface white, with golden-brown markings. South Brazil and Paraguay. — **campicola form. nov.** (140 h) from Corrientes differs by a bright yellowish-brown marginal band of both wings and by a considerable size. — **modesta** Meng. is smaller, the shades in the proximal half of the wings are duller and scarcer, and the white spots before the border of the hindwing are smaller; Paraguay and the adjoining part of Brazil. — Not rare.

zygia. **A. zygia** Hbn. (= caletor *Dalm.*) (140 g). Dark brown, with white and yellow dots, hindwing of the ♂ with a white colouring of the anal part, being continued upwards by golden-yellow; in the ♀ an irregularly shaped band runs from the centre of the forewing to the proximal margin of the hindwing. Guiana and Venezuela to the Amazon. Guiana-♂♂ differ from the (figured) Amazon-form by the yellow not being defined from the white of the anal part of the hindwing. The ♀ varies still more; in the form **chea** Hew. (140 g as *epione*) the band of the hindwing is narrow and that of the forewing continued to the costa by a small oblique band; *caliginea*. Bolivia, Amazon, inhabiting with typical ♀♀ the same district, but other flying-places. — **caliginea** Btlr. is a Mexican butterfly known to me only from the figure; it exhibits above only yet traces of the white, i. e. small chains of postdiscal spots on the forewing and an obliterated median diffuse spot on the hindwing; its position is not quite certain, since the figure and description are not very exact. — ♀-form **egaensis** Btlr. (= *amasis* Hew.), occurring not only on the Amazon, but also beside the other forms in Guiana, has a dull brown ground-colour and a uniformly curved, uninterrupted white band from the middle of the costa of the forewing reaching close to the front of the inner margin of the hindwing. *epione* Godt. refers to South Brazilian specimens that do not differ more from those from the Amazon than the latter differ among each other; of 16 specimens before me from Itaituba there are not 2 entirely alike; some belong to the form *baroptenosa* Stich. (more yellow dots of the forewing than white ones, ♀ like a *chea* but the band of the forewing without the strangulation in the middle); *peristera* Stich.: in the forewing more white dotting, only the discal area slightly dotted in yellowish, without the blackish-brown spot in the anal angle of the hindwing; from Bolivia. — Many such forms could be established from the copious material at hand.

agave. **A. agave** G. & S. (142 i). Likewise very variable; greyish red-brown, with dark spots; the distal part of the hindwing mixed with rusty-red. Forewing with 2 white spots, the costal one being small, the discal one larger; hindwing with a broad white band not reaching as far as the inner margin. Costa Rica to Colombia, the figured specimen from the Chiriqui in the Coll. BANG-HAAS. The ♂ differs from the figured ♀ by the costal of the forewing being very small and the anal part of the otherwise brown hindwing snow-white. There are, however, also ♀♀ that resemble these ♂♂, but are larger and somewhat more greyish-brown than red-brown. Rare; in thinly wooded savannas.

leucogonia. **A. leucogonia** Stich. Unknown to me; is not compared with any of the species known. The description runs thus: 1 ♂ from the Rio San Juan in Colombia; wings above brown, basal half darker, proximal dots, an angled discal transverse line, a row of dark small submarginal dots, hindwing with an oblong white anal spot. Under surface whitish, forewing with grey scales; proximal dot, row of discal dots and submarginal spots dark.

93. Genus: **Tharops** Hbn.

The butterflies of this genus are characterized by the very robust structure, the broad thorax, the uncommonly compact shape, the relatively short costal margin of the thick and hard wings. Only in the Gen. diurn. Lep. some are placed to *Lemonias*, otherwise they have always been dealt with separately owing to their deviating habitus. They have a somewhat whizzing, Hesperid-like flight and, in day-time in the sunshine, they visit blossoms on which they sit with their wings spread horizontally. Most of them exhibit, at least in the male, bright metallic colours with a very glaring lustre in the sun; in contrast with most of the other *Erycinidae*, some *Tharops* are common butterflies.

hebrus. **Th. hebrus** Cr. (= *pelidna* Hbn.) (138 d). In the ♂ the forewings are above spotted in a metallic blue; the hindwings entirely blue except the black-marked costal margin and apex. In the anal region a white brightening which, however, is covered so much with lustrous scales that it also shines blue in the sun. The ♀ is sepia-brown, with a red-shining apical area of the forewings; before this a blackish cloud behind which, at the costa, there often stands a small light spot. Guiana and the Amazon District. In Colombian ♂♂ the white of the hindwing is increased; in Bolivian specimens the white does not only cover half the hindwing, but it is also purer and rectilinearly cut off towards the metallic-spotted basal and apical parts; this is *ergines*. *ion*. **form. nov.** — On the contrary, **ion** Ww. (138 d) from Para exhibits the white of the male hindwing confined to the anal fold, the black apex of the forewing being unspotted. — **gemma form. nov.** (138 d) is the extreme form; the forewings have an entirely black costal half and of the white of the hindwing nothing whatever is noticeable. This form differs also entirely beneath from the typical form being blackish-dotted on a whitish-grey ground; its under surface is bestrewn with rusty-brown squares. In very dry districts, such as near Carabaya. — **cicuta** Hew. is presumably also only a form of *hebrus*. The ♂ is above of a lustrous light-blue, sparsely dotted in black, the apex of both wings and the base of the hindwings thickly black; ♀ dark brown, like that

of *ion*, but without the rusty red in the apex and the cloud below the costa, but dotted in black and with a black submarginal band. Amazon. — The species is not rare.

Th. clotho *Stich.* (138 b). This species not lying before me is based on a single ♀; the black upper *clotho*. surface is interspersed with diverse light markings some of which are of a blue reflection. We figure the type in the Berlin Museum, from Peru. Under surface greyish-yellow, dotted in brown; in front of the border lighter with a series of dark longitudinal spots.

Th. felsina *Hew.* (138 a, as *felina*). Sepia-brown, the distal part of the hindwing dull white. Under *felsina*. surface quite whitish, only the apex of the forewing darkened. Above darker markings, beneath dotted in blackish-brown. In the ♂ the white of the hindwing has a very faint bluish lustre. South Brazil. This species is rarer.

Th. pretus *Cr.* (138 c). Above black with golden-green undulate and dentate markings. Under sur- *pretus*. face dirty greyish-brown, with whitish and dark red-brown markings. East Brazil. — Colombian specimens exhibit duller green markings and have a yellow under surface being only in the ♀ more copiously marked in dark. — **picta** *G. & S.* (138 d) has a much more brightly lustrous, but more bluish-green marking of the upper *picta*. surface, the under surface being more copiously decorated with whitish squares. Central America; Bolivia. The ♀ is above like the ♂, also of the same lustre, but it is larger. The butterflies are like all the *Tharops* fond of the open country, not of the woods.

Th. menander *Cr.* (= *petronius Godt.*) (138 b). Above very difficult to distinguish from the follow- *menander*. ing species, but easily recognizable by the grey under surface exhibiting across the centre of the wings a somewhat dentate, brown shade projecting under the cell-end towards the base. Northern part of South America.

Th. nitida *Btlr.* (138 c) is the name of greenish-blue specimens with few dark spots above. According *nitida*. to STICHEL they originate from South Brazil, though the specimens from there mostly have a violet and not green reflection. — **thallus** *Stich.* is also said to have „often“ a greenish-blue ground-colour; moreover, the *thallus*. black in the apical part of the wings being reduced, it exhibits more distinctly the dark marking of it. As its patria the western part of the northern districts of South America is stated, though the forms are presumably difficult to separate geographically.

Th. coruscans *Btlr.* (143 e). Above very similar to the preceding and like there it is sometimes smooth *coruscans*. and bright as a mirror, sometimes very much black-spotted, with a blue, green or purple glossy upper surface. Easily distinguishable by the under surface being grey, at the border darker and the disc of both wings being rather uniformly covered with greyish-brown dots and comma-stripes. Of the small marginal spots those below the apex and in the anal part of the hindwing often are particularly bright. Amazon, Bolivia. Common.

Th. purpurata *G. & S.* (138 c). Above blue, less spotted, in the anal part of the hindwing 3 dark macular *purpurata*. bands above each other. Under surface yellowish-brown with whitish dusting and chestnut-brown marking. Central America.

Th. glaucoma *Hbn. G.* (138 b). Somewhat like the preceding species, but the hindwings in the ♂ almost *glaucoma*. without any markings, except the broad dark margin; most characteristic is the under surface exhibiting on the forewing large, on the hindwing small ringed eye-spots in front of the border. Brazil, rarer.

Th. splendida *Btlr.* Larger, the ♂ with a very pointed apex of the forewing and a long-stretched anal *splendida*. part of the hindwing. The black spots are arranged in 3 or 4 rows on the metallic bluish-green upper surface. The ♀ has on the forewing, above the blackish-brown disc, dispersed metallic bluish-green patches; in the hindwing particularly the costal part is of a bright light-blue. Para. — **superba** *Bat.* (143 c) from the Amazon is *superba*. presumably scarcely a different species; the ♂ has more rounded hindwings, above of a bright metallic green, in the disc of the forewing and the costal part of the hindwing of a pure cyan-blue; beneath the ground-colour is a rusty yellow. The ♀ has no more blue at all on the forewing; on the hindwing this is confined to the costal part. Apparently very rare.

94. Genus: **Dysmathia** *Bat.*

Mostly attached to the preceding genus, but of a considerably punier structure, the wings more delicate, the forewings very broad, the antennae shorter. Only 3 or 4 species are known from the Amazon and Guiana. The butterflies seem to be rare.

D. portia *Bat.* (138 a). The very broad wings above dark-brown with copious black spots arranged *portia*. in rows; the inner-marginal part of the forewing and the whole hindwings are above of a delicate violettish-blue lustre, though not reflecting as in the *Tharops*. Under surface dark yellowish-brown, the marking similar to that of above, the dark spots smaller. Guiana and Lower Amazon. — **glaucogonia** *Stich.* is somewhat smaller, *glaucogonia*. the small dark spots above partly covered up by small blackish clouds, the marginal area of the wings lighter blue; Guiana.

D. cindra *Stgr.* (138 a). Above quite pale sky-blue with irregular black streak-markings. Under sur- *cindra*. face still lighter, with a dark-shaded anal part of the hindwing. Twice as large as the preceding species. Lower Amazon.

costalis.

D. costalis *Bat.* Above greyish-brown, the forewings with 3 dark streaks in the cell and some irregular blackish markings; towards the border the colouring turns reddish. Hindwing with 6 dark lines, the 4th of which is bent and interrupted. Under surface bluish-grey, the marking similar to that above. Teffé.

95. Genus: **Pandemos.**

This genus, the 3 hitherto known species of which must yet be regarded as not fully ascertained with respect to their homogeneousness, comprises only large and rare animals. One species, *godmannii*, is presumably — anatomically it is not known — well attachable to the *Tharops* dealt with last; but I do not know the ♀ which may look quite differently and may approximate an *Eurybia*. The two other species are entirely unlike this species as well as among each other. Head stout with large eyes and a medium-broad, flat forehead, palpi projecting but not very long, with a thin terminal stylus, wings differently shaped in each species, in the ♂ of one species with black scent-spots.

godmannii.

P. godmannii *Dew.* (128 k as *godmani*). Forewings similar to those of the ♀ of the preceding species, but the white costal diffuse spot extends as a small curved band almost to the anal angle and the ground-colour is more red-brown than dark brown. The blue of the hindwing, which in *Tharops superba* is mostly covered by black in the distal part, covers here the whole wing except the yellowish-brown inner-marginal stripe. Undoubtedly very rare. The figure according to the specimen in GODMAN'S collection. Mexico.

pasiphaë.

P. pasiphae *Cr.* (= *arcos Cr.*, *ormenus Hbn.*, *perigone Godt.*) (128 k). ♂ with a less falciform, but still pointed apex. Here also the forewing is dusted with a dull violettish blue except the blackish apical part. Where the forewing and hindwing cover each other, there stands a black scent-spot. ♀ dull white with a broad dark margin of the forewing, of the exterior of a *Pieris orseis* (18 f). ♂♂ from Guiana have a blacker upper surface, those from the Rio Madeira a very bright blue one, and in ♀♀ from Colombia (Villavicencio) the border of the forewing has but quite a faint dark shade. Guiana to Colombia, Amazon and Peru.

*palaeste.**salvator.*

P. palaeste *Hew.* (128 k). ♂ above blackish-brown, the distal part of the hindwings with bluish-grey, sometimes greenish-lustrous longitudinal spots. Colombia. — In the form from Costa Rica, **salvator** *Stich.*, the bluish-grey radiate spots extend towards the base as far as beyond the centre of the hindwing, and before the anal angle of the forewing is a red semi-band. The ♀ is not described.

96. Genus: **Stalachtis** *Hbn.*

The *Stalachtis* are distributed from Central America to Paraguay and are almost all common animals. They are butterflies of more than medium size varying little in the shape, of a massive, in the ♀♀ clumsy structure. Head long, but not very broad; eyes large, palpi long, especially in the ♀, the end distinctly bent down. Antennae thick, filiform, at the end a scarcely noticeable thickened club. Thorax and abdomen strong, in the ♀ clumsy and so heavy that a flight like that of *Heterocera* or *Danaiid* is produced thereby. Legs stout and strong. Wings broad with a rounded border, shaped like the wings of *Actinote* or *Ithomiini*. In the veins the uncommonly long cell of the forewing is worth mentioning; the cell seems to some degree still more prolonged by the posterior discocellular reaching the 3rd radial only far beyond the rising of the upper median vein, which is also the case on the hindwing. The construction of the veins thereby makes a somewhat tugged impression, as if the wing had been stretched into a shape dissimilar to its original one, by secondary influences. This influence might be explainable by the effect of models (*Acraeini*, *Ithomiini*) which have influenced all the *Stalachtis* known without any exception. The larvae are very differently represented; the actual shape is presumably that of a compact, cylindrical body with small fine spines across the dorsum and at the sides; the pupa is fastened to the cremaster similarly to that of *Hades noctula*, of an oblong shape slightly strangulated behind the thorax, yellowish — or bluish — white with longitudinal rows of black spots (*St. calliope*). The butterflies are common; they fly in day-time in the sunshine, in a slow flight similar to that of their models, and drink from flowers; in this occupation they are so daring that they may be taken away by the hand if care is used. On being touched, they feign to be dead by folding up their wings above the back, bending the antennae under the body and folding their legs together; in this state they may be cautiously placed on the ground, like a captured *Gonepteryx rhamni*, without fear of their flying off immediately. Otherwise the animals rest beneath leaves with their wings kept flatly roof-shaped, the abdomen hanging down curved like a sabre.

*phlegia.**phlegetonia.**irion.*

S. phlegia *Cr.* (143 c). Black, body and wings covered with white dots, the base of the wings of a bright red-brown. Guiana, to the south as far as Para. — **phlegetonia** *Perty* (= *phlegia Hbn.*) (143 c) is the southern form flying in Central Brazil, Paraguay, and Bolivia; here there is yet a red-brown, irregular band between the basal brown and the border, as it is only sometimes indicated beneath in typical *phlegia*. — **irion**

form. nov. (143 c) is a very small pygmean form flying in May in (the town of) Goyaz. — **nocticoelum** *form. nov.* (143 c) is a form from Obidos, quite black with white dots, the brown at the base of the wings having disappeared except some traces of it. — **sontella** *Schs.* (143 d) finally is the form from Paraná; here there are only quite few white dots, on the upper surface of the body none at all; the shape of the body and wings, moreover, deviates considerably from the other *phlegia*-forms, so that I doubt whether it belongs to *Stalachtis*; the shape much rather resembles *Apodemia stalachtoides* from which, however, it differs by the silvery white (in the latter) abdomen which is red-brown in *sontella*. — In **venezolana** *form. nov.* (143 c) the brown-red colouring is replaced by a light orange, so that it resembles the following species. In some places rather common.

S. susanna *F.* (143 d). Similar to *phlegia*, but recognizable by the shape of the distal orange band which stands only in the apical part on the forewing. Besides there are never white or black dots on the orange parts of the wings. Near Rio de Janeiro the distal orange band on the fore- and hindwing is broad and indented in the middle of its proximal border; in Espiritu Santo these bands are already narrowed and in specimens from São Paulo they are interrupted. South Brazil.

S. euterpe *L.* Black, only the orange bands in the distal parts of the wings are present, no orange at the base. The black part of the wings covered with white dots and small longitudinal spots. — **latefasciata** *Stgr.* (143 b) which we figure from the Itaituba, has broader orange bands than typical *euterpe* from Guiana; and **adelpha** *Stgr.* (143 d) from Obidos, Pará and other places on the Lower Amazon has the orange band only in the forewing, in the hindwing it is above absent altogether and beneath only faintly noticeable. Common.

S. magdalenae *Hw.* (143 c). This and the following species imitate *Mechanitis* resp. *Melinaea*, whereas the models of the preceding species were *Actinote*. The apical part of the forewing contains 2 white macular rows, whereas in the whole proximal part of the forewing the orange colour is predominant. Black are some discal spots of the forewing, its inner margin, and the margin as well as a longitudinal stripe of the hindwing. Colombia, where also, though at other habitats (Rio San Juan), the form **cleove** *Stgr.* occurs exhibiting only one white macular row in the apical part of the forewing. Rarer.

S. calliope. Above orange-red with black stripes and spots, and a black, white-spotted apex of the forewing. As the typical **calliope** *L.* (143 b) the form in LINNÉ'S collection ought to be looked upon as correct. From Surinam; the spots of the middle stripe of the hindwing are separated by the red-orange veins, under surface almost exactly like above. — In **terpsichore** *form. nov.* (143 c) from French Guiana the black is considerably increased, the middle stripe of the hindwing no more broken up into spots, the apex of the forewing broader black etc. — **eugenia** *Cr.* (= *calliope auct.*) (143 b) has the hindwing entirely black except a red longitudinal stripe; Surinam, but at different habitats from those of the typical form. — **crocota** *Stich.* (= *calliope Clerck*) has distally yellowish-tinged forewings; this yellow discoloration occurs in all the modes of marking and is not bound to any place. — **voltunna** *Stich.* has the same light-yellow discoloration as *crocota*, but beneath, except a costal stripe, quite black hindwings. It is mentioned from Ecuador; but the Ecuador-specimens before me exhibit the black under surface of the hindwings, but above they are orange-red, without any yellow. — **bicolor** *Stgr.* has the apex of the forewing likewise orange-red, not broad black, but only quite narrowly bordered in black, with 4 or 5 black punctiform spots. — Common.

S. phaedusa *Hbn.* (143 d). Wings hyaline, with black veins and margins, marginal area broad orange. In Guiana-specimens also the inner-marginal part of the forewing is hyaline; those from the Amazon (Obidos) exhibit the latter dusted with violet. — In **exul** *form. nov.* (143 d) from the Kouron River opposite the Devil's Island the orange in the marginal band has disappeared except some faint traces. — In **phaloe** *Stgr.* (143 e) from the Upper Amazon the orange is greatly increased and the disc of the forewing scaled in violet. — In **duvalii** *Perty* only the hindwings have a broad orange marginal band faintly passing over only to the anal angle of the forewing; the hindwings, however, are like the forewings violet except small strigiform spots in and behind the cell. — Common.

S. zephyritis *Dalm.* (= *margarita* *Bat.*) from Guiana greatly approximates the preceding species, but it is recognizable by the white-powdered under surface of the hindwings; on the forewings the inner-marginal part is violet, on the hindwings the costal part is black, the other rest of the wings hyaline, with black veins. — **evelina** *Btlr.* (143 d) from the Amazon are *zephyritis* in which also cellules 1 b and 2 in the forewing are dusted with a bluish grey. — Not rare.

S. lineata *Guér.* (143 d). Wings black, between the veins narrow hyaline streaks, before the apex of the forewing an orange crescentiform spot. Lower Amazon. In specimens from the Rio Madeira the orange spot grows twice as large and has an oval shape. At other places in the Amazon District it grows, on the contrary, smaller and may disappear except faint traces; this is **trillii** *Btlr.* (143 e). Rarer.

97. Genus: **Aricoris** *Hw.*

This genus differs from the preceding by the mimicry being confined to the female sex which it has altered to the greatest extent. The only species not being sexually dimorphous resembles a Satyrid, but still it cannot be properly regarded as mimetic, since it has a somewhat different flight from that of the equally large *Euptychia* which might have served as models. This species, moreover, deviates from the other *Aricoris*,

so that STICHEL left it solely in the genus as being not congeneric, whereby it would become necessary to eliminate all the other *Aricoris* without exception from the genus. It probably suffices to distinguish 2 groups. As in the preceding genus, the palpi are somewhat projecting in the ♂, in the ♀ long, thin, lowered at the ends. The body of the ♂ is slim, in the ♀, however, uncommonly stout for a day-butterfly. The antennae are in the ♀ filiform, at the ends unnoticeably thickened, in the ♂ with small clubs being noticeable above. In the shape of the wings and in the veins both sexes of *Aricoris* differ from one another much more than the genus itself deviates from most of the other Erycinid-genera; only from the preceding genus they deviate by the subcostal and the upper radial of the hindwing branching off before the cell-end, instead of far behind it as in *Stalachtis*. The few forms I observed flew in the open country, most of them presumably occur in the forest. They are mostly rare and so incompletely known, that of many only one sex is known and one hardly knows how the sexes belong together.

epitus. **A. epitus** Cr. (= *cepha* F., *epiphanis* Stich., ♂ = *bias* F., *jaera* Hbn., *cataleuca* H.-Schäff.) (141 h). The ♂ is above quite black with a dull blue reflection, beneath blackish-brown with a whitish-powdered border, resembling a homochromous *Euselasia*, sometimes of this species, sometimes of that species, according to the (great) variability of its size. The ♀ has an orange basal part of the wings and in the distal part of the forewing a large, bone-yellow oval which is broadly confluent with the basal yellow in the ♀-form **cephisa** Stich. (141 h). — In **paroemia** Stich. it runs band-shaped through the distal part of the forewing and extends in a thin costal stripe as far as the base of the wing whereby the appearance of a *Methonella*-♀ is feigned. On the whole, the marking is variable; the bone-white and orange-yellow parts vary in size at every habitat, being in Guiana-specimens sometimes large, sometimes small, sometimes also discoloured to whitish. This species seems to be by far the most common *Aricoris*.

disparilis. **A. disparilis** Bat. ♂ very much like that of *lagus* (141 k), but without the white on the upper surface of the hindwings (which, moreover, seems to be absent also in all the continental *lagus*) and beneath with an irregular orange spot at the base of the hindwing. The ♀ has about the scheme of markings of *epitus*-♀ (141 h), but the white oblique band of the forewing is narrower, and the basal area of both wings yellow instead of red. From the Rio Tapajoz.

gelasine. **A. gelasine** Bat. (141 i). ♂ above black with a bright blue reflection and an irregular white discal spot. ♀ similar to that of *disparilis*, but the oblique band of the forewing likewise lemon-coloured. Beneath the dark margin of the hindwing is dotted in white. Colombia and Amazon; often in the so-called Bogotá-collections, probably from Muzo or Cundinamarca.

myrtis. **A. myrtis** Ww. ♂ scarcely differing from the preceding; ♀♀ that seem to me to belong to *myrtis*, have more yellow than *gelasine*, so that the yellow oblique spot of the forewing touches the yellow basal part of the forewing; hindwing with a narrower black margin. Amazon, Colombia. — STICHEL considers *myrtis* and *gelasine* to be subforms of one species which is not unlikely, if the variability of most of the *Aricoris* is taken into consideration.

butleri. **A. butleri** Bat. (141 i). The ♂ resembles that of *salvini* (141 k), but above the white spot of the forewing is smaller, the blue duller, beneath there is no honey-yellow basal spot of the hindwing. The ♀ resembles that of *gelasine*, but the forewing has no yellow in the basal part, but only the small yellow oblique band. Tapajoz. STAUDINGER believes that it belongs to *lagus* as a special form of it.

epilecta. **A. epilecta** Stich. Unknown to me. ♂ like *velutina* (141 k), black with a velvety blue reflection, the forewings more obtuse, the hindwings more oval. Beneath the cell of the forewing is filled with ochreous yellow, the hindwing with a reddish ochreous-brown costal area. ♀ with an ochreous-yellow band-shaped spot which is tinged reddish towards its proximal margin. Hindwings orange-red with a dark margin. Peru.

velutina. **A. velutina** Btlr. (141 k). ♂ above velvety black with a bright blue reflection, beneath dark brown, at the border broadly brightened up, but not whitish as in *epitus*. The ♀♀ are entirely black and have only on the forewing a pale orange oblique band running from the middle of the costa to the anal angle.

buckleyi. **A. buckleyi** Sm. The ♂ is beneath immediately distinguishable from the similar *velutina* by white, often triangular, small spots standing before the border and by long yellowish-brown rays extending from the base of both wings as far as beyond the centre of the wings. The ♀ is above blackish-brown with a large orange oblique spot of the forewing, beginning broadly at the costa, then growing narrower and terminating in front of the anal angle rounded off sacciformly. Ecuador.

phaedon. **A. phaedon** Godm. Above the ♂ resembles *velutina* (141 k), blackish-brown, with a violet reflection. Under surface lustrous dark-brown, between the veins ochreous. ♀ black, with a similar broad, but more ochreous and more regular band-spot of the forewing. Beneath the border of the hindwing is marked in white. Ecuador.

lagus. **A. lagus** Cr. (= *persephatte* Godt., ♀ = *petavia* Flör., *inquinata* Btlr.) (141 k). ♂ with tiny, dark discal spots on a black ground of a blue reflection. Characteristic is the under surface being whitish-grey traversed by brown veins. In the hindwing a brown nebulous stripe extends from the proximal margin to the distal margin. The ♀ is blackish-brown with an orange-yellow, but sometimes also bone-white oblique band of the forewing.

Beneath, the hindwings exhibit lighter veins and mostly (not always) small white triangles in front of the border. Guiana, Amazon. The species is beside *epitus* the most common *Aricoris*. — **pythioides** *Btlr.* seems to be a *pythioides*, western form of *lagus*; from the quite similar *salvini* (141 k) the ♂ differs by the light discal spot in the forewing being small and often darkened, and by the entire absence of the light-blue cellular spot at the base of the forewing above. — **striata** is a denomination by Druce for ♀♀ from Ecuador with a white oblique band, in which *striata*, the anal part of the hindwing above exhibits blue striate spots. The ♂ is said to be beneath entirely like typical *lagus*, exhibiting above a somewhat larger discal spot and, in the inner-marginal area a blurred blue dusting.

A. serica *Ww.* undoubtedly approximate the preceding, particularly *velutina*. The ♂ has apparently *serica*, no white discal spot, but the metallic lustre extends almost over the whole forewing, so that only a broad costal stripe and the apical part remain black. In the hindwing the reflection is chiefly confined to the part between the lower cell-wall and the anal fold. Amazon.

A. amethystina *Btlr.* ♂ above black, with a violetish-blue reflection and a shortened white oblique *amethystina*, band; beneath like *pythia*, but it has a more stretched costal margin of the hindwing than the latter and was, therefore, looked at as another species. The ♀ is not described. From Santarem on the Lower Amazon.

A. pythia *Hew.* entirely resembles *salvini* (141 k), but it is smaller, the white spot of the forewing in *pythia*, proportion to the forewing larger, the hindwing blue only in the anal part. ♀ blackish-brown with a white oblique band having the shape of the yellow band in *lagus* (141 k). — **salvini** *Stgr.* (141 k) has above a white *salvini*, oblique spot of the forewing of the ♂ which is sacciformly expanded in the ♀; the ♂ has an almost entirely light-blue, dark-veined hindwing, exhibiting beneath a yellow basal spot; the ♀ has beneath, at the hindwing, triangular, white marginal spots. Upper Amazon and (somewhat less blue ♂♂) also in Colombia and Bolivia.

A. cyanea *Btlr.* ♂ above black, with a blue reflection and an indistinct white discal spot; ♀ with *cyanea*, an orange oblique band and a blue-reflecting disc of the wings. Upper Amazon, Ecuador. In the collections there is mostly the Central American form **jansonii** *Btlr.* (143 a). The ♂ has a large white discal spot, the ♀ *jansonii*, a more flatly drawn out orange band. Both forms, moreover, occur beside each other, and the shape and position of the oblique band varies to such an extent that entirely alike specimens come only from the same flying-place. Near Orosi (Costa Rica) the band is very broad, near Chontales (Nicaragua) uniformly band-shaped, narrower and lighter yellow, near Burica in Colombia behind the cell somewhat strangulated etc. Beneath the ♂ shaded in a sepia-brown, except an oblique band in the forewing and white, towards the margin thickened rays in the hindwing.

A. alcmaeon *Hew.* (142 k). ♂ above and beneath dark-brown; above there is a violetish-blue stripe *alcmaeon*, above the inner margin of the forewing, and the hindwing is entirely violet, the veins black. Under surface without markings. Ecuador; we figure a specimen from Paramba. — **maja** *Godm.* (141 k) has above quite black *maja*, forewings and the hindwings have only at the border a brighter blue colouring; but the under surface also exhibits submarginal blurred spots. The ♀, in contrast with the preceding species, is more similar to the ♂, but in front of the distal margin it has white-blue wedge-shaped spots. Colombia.

A. rhodinosa *Stich.* „♀ of the shape of an *epitus*-♀ but a little smaller; above black, the forewing with *rhodinosa*, a broad, oblique pink band, the hindwing with long blue rays between the median veins; under surface paler with few whitish basal streaks, the hindwing with rusty-yellow veins and white submarginal spots.“ The type is a ♂, but it is not described *). From Sarayacu (Ecuador).

A. megalia *Stich.* Certainly a form of the preceding, a little larger (24 against 22 mm). Differing by *megalia*, a broader pink band of the forewing and more distinct blue rays of the hindwing. Peru.

A. fassli *sp. (?) nov.* (143 a). Considerably larger than the preceding (length of forewings 29 mm). Disc *fassli*, of all wings, except a costal stripe, of a bright metallic cyanic-blue. In front of the marginal part of both wings a light-red band of a magnificent purple-violet reflection, being on the forewing nearly twice as broad as on the hindwing. Under surface brown, the bands dull pink. Rio Songo, at an altitude of 750 m. Type a ♀ in FASSL's collection. — I am of opinion that all the 3 species described last are forms of *one* species.

A. tapaja *Sndrs.* (143 a). ♂ blackish-brown, forewing with a hemochrome, rather straight median *tapaja*, band. Under surface brown with a submarginal row of white dots. The ♂ varies at every habitat; sometimes the bands are hemochrome and on both wings (typical specimens, if the bands are absent beneath), sometimes the band of the forewing, or that of the hindwing appears also beneath; then again the band of the hindwing may be absent altogether (*hewitsoni* *Ky.*) and the band of the forewing may appear beneath instead; sometimes again the band of the forewing is above broader and bent round like a hook, the colour more crimson than hemochrome etc. As the ♀, STAUDINGER figures a butterfly with orange-yellow, distally black forewings and

*) I first took it to be a misprint that a ♀ is described of a species the only type of which is a ♂, but E. STRAND confirms once more in another work (Lepidoptera Niepeltiana, p. 51) that the type is a ♂.

blackish-brown hindwings; in front of the apex of the forewing a yellow band, before the border white dots. The ♀ will presumably vary just as much as the ♂; sometimes the forewings are carmine instead of yellow. Rare.

flammula. **A. flammula** *Bat.* (143 b). ♂ blackish-brown, before the apex a white oblique band and at the inner margin as well as on the hindwing hemochrome colouring. The rare butterfly of which not many specimens are known, presumably varies just as much as the preceding species. I figure a ♂ from Surinam; Amazon-♂♂ have more red in the forewing, the hindwings are not so very lobate, and on the under surface of the hindwing (where our specimen has only a moderately broad light ray) the whole disc is white. Guiana, Amazon. The ♀ resembles about a *Methonella*-♀ (122 i).

cruentata. **A. cruentata** *Bltr.* (142 h). ♂ glaringly light-red with a narrow black border; under surface yolk-coloured, the margin more greyish-black, but somewhat broader than above. It varies at every habitat; the dark border may grow considerably broader and enclose white pupils also in the ♂, so that the exterior approximates more the following form. The ♀ has a broadly dark distal part of the forewing and in it a white, band-shaped spot.

heliodora. — **heliodora** *Stgr.* (♀ = *cruentata* *Stgr.*, *helice* *Godm.*) is a form not before me in nature, but certainly allied to the preceding. Here the white subapical spot is band-shaped and stands in the broadly black apical part; in the ♀ it is confluent with the basal red. The species has the attire of certain *Mesene*, of *Lemonias luceres* and so on; but certainly only secondarily, since both imitate certain night-butterflies (*Arctiidae* and *Geometridae*) which are very often met with in the tropical parts of South America.

terias. **A. terias** *Godm.* (142 h). This butterfly, which is not very rare in summer in Paraguay (e. g. Sapucay), is, in spite of its deviating colouring, a genuine *Aricoris*, as is seen by the antennae being not thickened at the ends, but only somewhat bent, and by the long palpi being lowered in the ♀, as well as the whole structure. Dull yellowish-white with a black border, similar to one of the *Terias* frequently flying there. Beneath, the forewings are yellow, the hindwings brown with white rays.

tutana. **A. lutana** *Godt.* (= *tisiphone* *Dbl.* and *Ww.*, *bahiana* *Fldr.*) (141 g) exhibits a somewhat deviating structure and, above all, not sexual dimorphism being otherwise characteristic of the *Aricoris* and appearing also in *terias* only faintly developed. These species are, therefore, better placed into another group from the other species. *tutana* is on both surfaces unicolorously dark brown; in the form of Casa Branca in Brazil (= **monotona** *Stich.*, 141 g) almost without markings, in typical *tutana*, as they occur near Bahia and as I captured them myself in the gardens of the town, with a slightly marked under surface. Single, but not rare.

cleomedes. **A. cleomedes** *Hew.* certainly does not belong here; it resembles *Lepricornis bicolor* (136 b) and is perhaps better placed near that genus. — Nor can **aurigera** *Weeks*, which is likewise not before me, be an *Aricoris*, if it has the structure of the palpi deviating from this genus, stated by STICHEL (*Berl. Ent. Ztschr.* 55, p. 71). The same is the case with **hippocrate** *Godm.* which almost looks like a small, somewhat narrowly and light-banded *lagus*-♀ (which, by the way, has incorrect antennae in our figure 141 k), but which may also represent a somewhat aberrative ♀ of the greatly varying **A. jansoni**.

98. Genus: **Theope** *Dbl.*

The forms of this genus, of which more than 50 were described, may be reduced to quite a moderate number of species. Nearly 70 percent of them occur in the Amazon Valley. Some forms that are very much alike each other and come from the same district, make the impression as if they were only so-called deviations of the flying-place, so that they may be valued only as subraces. If we were to describe as new forms all those specimens that are not in every detail adaptable to the diagnoses mostly set up by BATES, their number would increase considerably. Whereas the *Theope* resemble in their exterior somewhat the *Lycaenidae* which, however, is more due to their colour than to their structure, they are still to be considered genuine *Erycinidae* by their neurulation, the palpi and antennae, the eyes, though not circular, are never bean-shaped, and have the well-developed forefeet of the ♀♀ etc.; besides the only larva having become known hitherto (of *Theope eudocia*) most conspicuously exhibits the neck-organ so characteristic of *Erytinidae*. The *Theope* mostly are very rare; in contrast with most of the other *Erycinidae*, they frequently sit on the upper surface of the leaves with raised wings and are mostly found only at quite circumscribed localities; a great number of forms has never been discovered again except by their authors.

pieridoides. **Th. pieridoides** *Fldr.* (143 f). White, above with a blackish apex of the forewing. In the ♀ the wings are not so pointed and the apical black is narrower. The butterfly is very rare in Bahia, from where it is described and from where also the figured specimen (a ♂) originates. As the most common butterflies in Bahia are entirely white *Hesperiidae* (*Leucochitonea*), it is probably also very difficult to recognize.

eudocia. **Th. eudocia** *Ww.* (143 f). Above orange-red with a broad black costal and apical part of the male forewings. In front of their apex a large diffuse spot of a violettish-grey lustre. Under surface brass-coloured, without the dark margin. — Colombian specimens exhibit less black and no diffuse spot in the dark apical part; we figure them from East Colombia (from the Coll. FASSL). STICHEL denominates them **acosmia** (143 f)

stating, however, their patria to be the Western Amazon; — Central American specimens in which the whole cell of the forewing is yellow, with a narrower blue spot, are denominated *pulchralis* *Stich.*, their patria is also *pulchralis*. stated yet to be „Colombia“. Thus presumably two forms occur there, according to the situation of the finding-place. The typical *eudocia* flies in Guiana and Venezuela. — Larva green with a black, white-marked head, surrounded by fine fluffy hair. At the neck it exhibits lateral clusters of small brown cones and at the anal end a glandular organ which is licked off by ants. The larva lives in a rolled-up leaf of the cocoa-plant in the surroundings of which the ants of the guard build their paper-nests; on trying to separate them from their larva, they appear very excited (GUPPY). Pupa green, held by the cremaster and a filiform belt. The butterflies are not common.

Th. pedias *H.-Schäff.* (♀ = *helpusa* *Hew.*) (143 f). Above violettish-blue with a black costal- and *pedias*. distal margin of the forewing, beneath one-coloured and unmarked golden-yellow. In the ♀ also the distal half of the inner-marginal part of the forewing above is black. From Guiana and Colombia to South Brazil and Bolivia. — **isia** *G. & S.* are specimens from Mexico and Central America, exhibiting a greyish-yellow dull *isia*. under surface. — **hypoxanthe** *Bat.* from Pará has a brass-coloured, lustreless under surface. — Less rare. *hypoxanthe*.

Th. sericea *Bat.* (143 f). Similar to *pedias*, but larger; the apical part of the forewing broad, the margin, *sericea*. however, only narrower black; the rest of the wings violettish-blue, as *pedias*. Under surface of a magnificent golden red in the ♂, more yellow in the ♀. Amazon. Rare.

Th. lampropteryx *Bat.* Of the shape of *pedias*, but the forewings only at the base blue. Under sur- *lampropteryx*. face ochreous-yellow, only faintly lustrous. Lower Amazon.

Th. caenina *G. & S.* Similar to *barea* (143 g); in the ♂ the forewings are dark brown, the cell to *caenina*. its end, the inner margin of the forewing and the whole hindwing are violettish-blue. Under surface almost light yellow. From the Chiriqui (Panama).

Th. barea *G. & S.* (143 g). Like the preceding, but below more brass-coloured than pale yellow. *barea*. Upper surface light-blue, lustrous. Behind the cell of the ♂ a spot of a silky gloss. Panama to the Amazon. Not common.

Th. excelsa *Bat.* (143 f). The largest species of the group; more than twice as large as the preceding. *excelsa*. Beneath abundantly brass-coloured with a faint lustre. Wings with a dark violettish-blue lustre, forewings with broad dark costal- and apical parts, and with a broad dark marginal band; hindwings only at the costal margin black. Amazon; if I have identified the species correctly by the short description by BATES, it also occurs in Guiana.

Th. aureonitens *Bat.* Very similar to the preceding, but much smaller, the blue of the hindwing reaches *aureonitens*. the costal area; in the disc of the ♂-forewing a dull brown spot. Under surface of a golden-yellow (♂) or straw-coloured (♀) lustre. Teffé on the Amazon.

Th. simplicia *Bat.* As large as *eudocia* (143 f). Forewings unmarked blue, hindwings violettish- *simplicia*. blue; under surface dull whitish. The ♀ has a dark base of the hindwing. Pará. Not rare.

Th. hypoleuca *Bat.* Similar to the preceding, somewhat larger, recognizable by the almost purely *hypoleuca*. white, unmarked under surface; above both sexes are of a more brightly lustrous blue (about like *Lycæna icarus*), costa narrow and the distal margin of the forewings broadly black. Lower Amazon.

Th. azurea *Bat.* resembles the preceding, but it differs by the shape; the ♂ has more triangular *azurea*. forewings with straight margins, whereas *hypoleuca* exhibits a somewhat bulging costal margin and a convex border. Upper surface of a bright blue-lustre, costa narrow, apex and border of the forewing broadly black. Under surface quite light brownish, unmarked. Amazon.

Th. herta *G. & S.* (143 g) is a rather small species the ♂ of which is above almost blackish-brown, *herta*. in the basal area there are hardly any blue radiating patches. The under surface is light earthy-grey, mostly almost without any marking at all, sometimes in the centre of the wings slightly darker. The species does not seem to be more closely allied to any other and to be very rare in its patria, Central America.

Th. lycaenina *Bat.* Size of *azurea*; deviating from the preceding species by the almost white under *lycaenina*. surface being faintly tinged brownish-grey. Upper surface black and, as in *herta*, only the inner part of the wings with an indistinctly defined blue (and only dull) lustre. Beneath the hindwings exhibit a series of dark dots being distinct only in the anal region. East Brazil, Pará, Espiritu Santo.

Th. foliorum *Bat.* has the size of *sericea* (143 f). Forewing black except a blue triangle above the *foliorum*. inner margin covering about one third of the wing. The hindwings are above all light-blue, with a dark margin. In front of the border is a series of black, white-shaded dots. Under surface brownish-white, with few black dots before the border. ♀ with obtuser wings. Lower Amazon. — **punctipennis** *Bat.* is like *foliorum*, but smaller *punctipennis*. and the submarginal dots of the hindwings are more numerous and some appear also on the forewings beneath. Amazon and Venezuela. — **atima** *Bat.* likewise entirely resembles *foliorum*, but beneath it is darker and distinguished by the forewings being all black except a very narrow blue stripe in and below the cell. Teffé. *atima*.

Th. leucanthe *Bat.* (143 g). If I identify *leucanthe* correctly in the figured small animal looking almost *leucanthe*. like a *Lycænidæ*, according to BATES' short description, it is above blackish, only in the basal part and on

the hindwing blue, in front of the border are fine blackish dots in a light halo. The under surface is unicolorously whitish-grey with very fine dark dots on the hindwing and in the anal part of the forewing. Amazon.

phineus. **Th. phineus** Schs. Described from Limon in Costa Rica. Forewings dark brown; cell posteriorly as well as the space below it as far as behind the middle of the wing bright blue, also the space between veins 3 and 5 up to close to the border. Hindwing likewise blue, only the costal margin and apex narrowly black. Under surface light brownish-grey, hindwings with black marginal dots the largest of which at the anal angle and below vein 3.

methemona. **Th. methemona** Bat. is considerably larger than the preceding, the forewings form a more regular triangle; the disc and base of both wings are blue, sharply delimited against the broad black margin; under surface light-brown. Forewing and hindwing with thick submarginal dots. Lower Amazon.

theritas. **Th. theritas** Hew. (143 g as *thersitas*) is larger and has a bright blue ground-colour with an intense lustre on the inner part of the forewing and on the whole hindwing. The under surface is light ochreous-brown with 2 black submarginal dots in the anal part of the hindwing. Amazon.

diores. **Th. diores** G. & S. (143 h). Differing from the preceding species chiefly by the costa of the forewing being more stretched and the black in the forewing being more extensive. Under surface very much like that of the preceding; in the anal part mostly only 1 dot. Mexico; mostly rare.

virgilius. **Th. virgilius** F. (143 h). One of the largest species varying exceedingly. Typical specimens come from Central America; the ♂ has more than half of the forewing black, but no blue pupil in the black apical part. The under surface is uniformly tinged in a pinkish brown. — **eupolis** Schs. (143 g) has the blue of the forewing in the ♂ confined to the basal part of the inner-marginal area; in the ♀ it is more violet, more extensive, and in the black apical part is an indistinct blurred spot. The under surface is more flesh-coloured than brown and has only 1 tiny eye-spot in the hindwing. Mexico; near Guerrero not very rare; before me also from Jalapa,

eupolis. and in a remarkably small, more lilac-blue ♀ from Honduras. — **polimela** G. & S. has the upper surface of typical *virgilius*, but without distal-marginal dots of the hindwings; the black of the apical part in the forewing somewhat reduced; the under surface of the hindwing without an eye-spot in the anal part. Colombia.

polimela. — **caerulea** Bat., finally, is the South Brazilian form, is said to be more cyanic-blue than violetish-blue and *caerulea*. the hindwing has darker veins and between them small, dark submarginal streaks. — **nobilis** Bat. is the Amazon-*nobilis*. form; it is particularly large and has a more yellow than brown or pinkish-grey under surface with several small spots before the border. In some places common. — It may be that also **archimedes** F., unknown to me, *archimedes*. belongs into this group; it is said to be marked similarly above and to have a greyish-brown under surface. The patria of this latter form not being known, it is undoubtedly difficult to ascertain.

speciosa. **Th. speciosa** G. & S. (= *fasciata* Lathy). Beneath just as monotonously coloured as the preceding, entirely earthy-grey with faint dark anal dots of the hindwing in a light halo. Above, however, also the ♂ exhibits in the black apical part a lustrous blue spot of a violet reflection, being by far larger than in the ♀♀ of the preceding species. Colombia.

publius. **Th. publius** Fldr. (143 h). This butterfly, like the ♀♀ of *virgilius*, has a bright blue spot in the black apical part of the forewing, but also in the ♂, where *virgilius* is without it. But besides the under surface is entirely different, chestnut-brown with a more deeply brown median shade of all the wings. Widely distributed and not very rare. From Panama to the Amazon.

comosa. **Th. comosa** Stich. Also here the ♂ has in the apical black of the forewing a blue pupil, like in *publius* (143 h) to which the upper surface is said to be similar. (But according to the figure in the „Genera Insectorum“, this blue spot is at a different place, from that of *publius*, at the cell-end, whereas there it is nearer to the apex.) The under surface, besides, is monotonously yellowish-grey, unmarked. Described according to a ♂ from. Pebas (Peru).

talna. **Th. talna** G. & S. (143 h). From Honduras. Resembles *virgilius* (which, however, likewise flies in one form in Honduras); the blurred spot in the black apical part of the forewing is present, but otherwise the blue of the upper surface almost entirely confined to the base of the wings; the under surface exhibits a whole chain of anal dots of the hindwing.

cratylus. **Th. cratylus** G. & S. (143 e). This species, one of the largest of this genus, which we figure from the Chiriqui, neither in the ♂ nor in the ♀ has the black apical part of the forewing blue-pupilled. It is immediately recognizable by the somewhat irregular delimitation of the blue in the forewing, where it projects towards the apex, and by the dark border of the hindwing. Panama.

thootes. **Th. thootes** Hew. (143 i). Much smaller than the preceding, at once distinguishable by the blue of the forewing projecting behind the cell in a tip towards the margin and advancing a second time between the lower median vein and the submedian, but here as far as to the distal margin. Undersurface unicolorously greyish-brown, unmarked. Central America to the Amazon.

Th. zostera Bat. Above similar to the preceding, but the blue more extensive, so that only a black marginal band remains being deeply indented in the middle. Under surface entirely different; the here brownish-yellow wings are crossed by a brown belt. From the Upper Amazon.

Th. apheles Bat. Likewise from the Amazon; very similar to *thootes* (143 i), but smaller and lighter blue. Beneath light brown. — **sobrina** Bat. presumably likewise approximates *thootes*; described according to a ♀; like *thootes*, but more violettish-blue instead of cyanic blue, and the under surface of a lustrous golden brown. From the Tapajoz.

Th. terambus Godt. (= *lytaea* Hbn.-G.) (143 h, i). The ♂ has a similar upper surface like *virgilius*, but a bright blue gloss and a very pointed apical part of the hindwing. The ♀ has no blue pupil in the apical black of the forewing. Immediately recognizable by the under surface, where the wings, on a brown, in the ♀ yellowish-tinged ground, exhibit a dark-brown stripe extending from in front of the apex of the forewing to the middle of the inner margin of the hindwing. South Brazil. Not common.

Th. tetrastigma Bat. This much smaller species is above unicolorously brown, without markings. The under surface is dark brown too, but here are short light streaks at the end of both wings and, in front of the border black dots in a light halo. From the Tapajoz.

Th. thentis G. & S. This form, in the distribution of the blue, so greatly resembles *thootes* (143 i) that it was sometimes confounded with it. Like there, the black distal band of the ♂-forewing projects linguiformly as far as below the cell-end. But the forewings are much more pointed, the apex still more produced, the costal margin behind the base more bulging-out. Moreover, the under surface in *thootes* is entirely unicolorous, whereas here it is marked with dark shades. Central America.

Th. bacenis Schs. Larger, forewings black, proximal margin at the base broadly blue, hindwings blue with a black costal margin. Under surface brown with an intensely brown, joint band running from the apex of the forewing, similarly as in the following species, to the middle of the proximal margin of the hindwing. Forewing at the base yellowish. Mexico. Unknown to me.

Th. phaeo Prittw. This is probably nothing else but the South Brazilian form of *folia* G. & S. (143 i) living in the northern parts of South America and in Central America. This species has altogether the distorted shape of *thentis*, very pointed forewings and a pointed anal part of the hindwing, but the colouring is that of *virgilius* (apical half of the forewing blackish, otherwise blue) which it approximates also in the size. Beneath dirty pinkish-grey; the centre of the wings is traversed by a dark nebulous belt. Rare.

Th. basilea Bat. (143 i). One of the largest species, above similarly coloured to *terambus* (143 h, i), but both sexes with a dark border of the hindwing, which decreases in width from the apex towards the anal angle. Under surface brown, with a dark stripe from the apex of the forewing to the proximal margin of the hindwing, like in *terambus*, but the dark ground of the wings is, in the disc, usually still more or less distinctly spotted. Central America. Not common.

Th. eleutho G. & S. The largest species; greatly approximating the preceding, but easily discernible by the much broader black distal margin of the hindwing and by the under surface exhibiting also the belt-like stripe as *basilea*, but a lighter, more marked ground of the wings in which, above all, a chain of marginal eye-spots of the hindwing is conspicuous. Panama.

Th. mania G. & S. from Mexico is of a similar size and colouring, but easily distinguishable by the unicolorously loam-yellow under surface being traversed only by the median stripe, as well as by the hindwing of the ♂ exhibiting no dark margin. Rare.

Th. syngenes Bat. Beneath rather similar to *mania*, but the hindwings always exhibit a distinct dark anal spot, and at the apex of the forewing, at the beginning of the dark stripe, we notice a mostly somewhat square spot. Above the blue on the hindwing is more confined; the veins are distinctly brown; in the ♀ the black apical part of the forewing often shows a blue spot. Santarem.

Th. thebais Hew. This species has a deep dark-blue of a magnificent lustre, as it is exhibited by different *Thecla* and, of the Indian *Lycaenidae*, particularly by the *Arhopala*. Especially the form *matuta* G. & S. (143 i, misprinted into *matula*) exhibits this deep blue, and still more extensively than typical *thebais*, but in this respect the *matuta* from the different districts vary considerably. The fore- and hindwings are very broadly margined in black; particularly in typical *thebais* from the Amazon, where the blue covers scarcely yet $\frac{1}{3}$ of the upper surface of the wings. Beneath *thebais* shows a broad brown median band and a submarginal nebulous stripe; in *matuta* the under surface is more regularly brown, the veins distinctly darker, the transverse bands duller; it occurs in Central America and in particularly large specimens (*gloriosa* B.-H. i. 1.) in Colombia.

Th. janus Btlr. In this species from the Lower Amazon the proximal half of the wings shows beneath a yellow colouring which does not occur in any other allied *Theope*. Only *decorata* shows yet a basal yellow on the wings beneath, but only in the cell of the forewing; the latter, however, has also blue in the distal part of the forewing beneath and is smaller than *janus*.

Th. drepana Bat. A small species; the costa behind the base bulged and, in the ♂, the apex of the forewing greatly drawn forward. The forewings being above blue exhibit a dark margin and 2 very irregular lines formed by small streaks. Beneath are numerous, small red-yellow stripes on a lighter ground, being partly united to a belt-like stripe through the centre. Teffé.

- thestias*. **Th. thestias**. A very small form; it is immediately recognizable by the under surface. Here, below the costa of the forewing, we see a brimstone-coloured, oblong basal spot filling up the part of the wings between the costa-base and the subcostal, and extending yet narrowly into the cell of the forewing. The rest of the under surface is lilac-grey, with a broad brown median shade. Above typical *thestias* have entirely blue hindwings. — Those of the form **discus** *Bat.* have only the basal part of the hindwing blue. The species is easily distinguishable by a concave indenture at the anal part of the hindwing, effected by the receding anal fold. The species, varying according to the finding-places, not with respect to the countries, is apparently distributed over the greatest part of Central and South America; it was found from Costa Rica and Guiana to Rio Grande do Sul and Bolivia. — **decorata** *G. & S.* is the northernmost form; it shows blue patches embedded in the distal part of the forewings beneath. Apparently rather rare.
- eurygonina*. **Th. eurygonina** *Bat.* Recognizable by the shape being more that of an *Euselasia* than that of a *Theope*; the forewings are triangular with almost straight margins, and the hindwings have a rather long anal part. In the typical form from Santarem on the Amazon, the part of the forewing above the middle of the inner margin, the hindwing, however, entirely violetish-blue except broad dark marginal triangles of the ♀.
- columbiana*. Under surface brown, marked with rusty-brown transverse bands. — Colombian specimens, **columbiana** *Stgr.* (110 A e), are figured by their author with a light-brown, light-striped under surface and entirely blue hindwings, from the Rio San Juan; a specimen captured by A. H. FASSL on the Tolima at 1700 m has the whole distal half of the hindwings blackish, only the basal part being blue; the under surface shows very light grey bands. — From the Rio Dagua (Colombia) there is a most peculiar specimen before me, likewise taken by A. H. FASSL, which is similarly marked like the Tolima-specimen, but of a snow-white colour in the centre of the wings on both surfaces. It is not impossible that it is a different species, as also the marking beneath in the centre of the wings deviates somewhat from *eurygonina*. But as I have only 1 specimen before me, I include
- sisemina*. it here and call it **sisemina** *form. nov.* (110 A e). — This species connects the genus with the preceding.

Additions and Corrections.

- fulvescens*. P. 623. — **Libythea fulvescens** *Lathy* (Proc. Zool. Soc. Lond. 1904 p. 451) scarcely differs from the form *terena*; it has only above more black and the yellow spots are more homochromous. From Dominica.
- P. 624, line 12 from above, insert: typical *eucritus* *Hew.* (121 a) originate from the Central Amazon.
- P. 626, „ 11 „ „ After *eustachius* insert: *J. & Hbst.* (121 e).

- pactula*.
- P. 642, line 12 from above. *M. mathania* *Schs.* which was wrongly placed to the *epidius*-group by STICHEL, belongs to the *odice*-group, according to the ♀ having in the meantime become known, and approximates *cymotaxis* *Stichel*.

P. 643. — Hereto we must remark that the two first figures of the row e of table 142 are exchanged by mistake.

P. 648, line 13 from above and Note: **M. ramsdeni** *Skinn.* Blackish-brown, forewing with 2 whitish *ramsdeni*. costal spots and a similar transverse band shaded inside in dark; at the distal angle a black spot of about 2 mm, near the base 4 small dark crescents. The hindwings at the anal angle have a black eye-spot narrowly bordered in orange, at the base 2 black bands, at the distal margin 3 obliterated dark spots. ♂ has an expanse of 30 mm. Unknown to me.

P. 651, line 25 from above, add: *Napaea agroeca* *Stich.* Forewing more pointed, border less convex. *agroeca*. Wings above greyish-brown, outside darker. Espiritu Santo.

P. 652, line 17 from above, for *helydrias* read *thelydrias*.

P. 654, „ 1 „ „ To *Tmetoglene* apparently belongs an *Erycinidae* which I call **trichroma** *trichroma*. *sp. nov.* (110 D f) and which was brought by A. H. FASSL from his last excursion to Colombia. Like *Tm. dodone*, but the basal half of the wings orange-red.

P. 655, line 19 from below, behind *jaeris* place *Bat.* instead of *Bsd.*

P. 658, „ 5 „ above, **Panara trabealis** *Stich.* (1916) is above blackish-brown, hindwing in the *trabealis*. anal region powdered in white; oblique band across both wings 3 to 4 mm broad, pale reddish ochreous-yellow, the costal end diffuse towards the base. Length of forewings 19 mm. Sao Paulo (South Brazil).

P. 658, line 17 from below. **Riodina pelta** *Schs.* Upper surface dark violettish black, between the *pelta*. veins greenish-brown streaks, the orange band in the forewing from the middle of the costa to the anal angle. Under surface black, internerval streaks lighter. Costal margin of the forewing at the base orange, oblique band paler; hindwing with a yellow dot at the base and a small orange dot near the anal angle.

P. 662, line 14 from above. *Lymnas hodia* *Btlr.* is allied to *jarbas (melantho)*; upper surface jet- *hodia*. black, the orange band of the forewing narrow; under surface lighter, more dark-brown with whitish veins, the oblique band paler. Forewing above with a deep-red dot near the base, sides of the body with a scarlet stripe. Venezuela. Type in the Coll. Druce.

P. 665, line 7 from below, for „oldros“ read „oluros“.

P. 666, „ 2 „ above, behind *naevianus* *Stich.* place: (130 e).

„ 22 „ „ for „Euerciina“ read „Euerycina“.

P. 671, „ 1 „ below, add: *Monethe albertus* with an ochreously darkened spot of the forewing are *nesotypus* *Stich.* — *paulus* *Stgr.* is synonymous with *albertus*.

P. 675, line 3 from below, add to *hya*, as well as to *fenestrella*: (110 A e). As presumably all the forms quoted as *hya* replace each other in the different districts, there may transitions be found, we therefore better figure these 2 forms once more.

P. 676, line 1 from above, for „paraene“ read „paraena“.

P. 679, „ 15 „ „ for (142 g) read (135 d and 142 g).

P. 681, „ 15 „ „ — STICHEL describes (Berl. Ent. Zschr. 1910, p. 81) as *Symmachia histrica*, according to a single ♀ of his collection a butterfly which is said to resemble *S. calligrapha* in the shape of the hindwing, in the forewing, however, a *Mesene*. Blackish-brown, forewing with 4 ochreous-yellow transverse lines the 3 rd of which bifurcates towards the costal. In front of the border blackish, coherent spots. Hindwing with similar markings. From Panama.

P. 686, line 9 from below, behind *micon* read *Drc.* for *Stich.*

P. 687, „ 24 „ „ behind *axiochus* *Hew.* place: (= *archytos* *Stoll*).

P. 693, „ 14 „ „ insert: **Z. candace** *Hew.* (135 l) ♂ similar to the following, but only at *candace*. the costal margin and base of the wings with scarce dots as small as the prick of a needle. ♀ loam-yellow, clouded in a dirty brown, with a chain of antemarginal eyespot-rings. From the Amazon.

P. 694, line 15 from above, for *hegyas* read *hegias*.

P. 695, „ 3 „ below, before *E. angularis* place: **E. samius** *sp. nov.* (136 g) from the Pachitea *samius*. (Peru) has all the wings unicolorously nut-brown marked with somewhat irregular darker transverse bands. ♂ quite slightly darker than the ♀, but the wings more pointed. Beneath almost like above, the transverse line more distinct, ending into dark comma-spots. ♂, in the Coll. BANG-HAAS.

P. 696, line 1 from below. Behind „not common“ add: Colouring of the upper surface suffused by an intense yellow with very dull silvery markings, similar to *poeas*.

P. 697, line 7 from above, to *Emesis temesa* add: **E. satema** *Schs.* being unknown to me. Wings *satema*. above quite dark brown, with still darker markings. The markings are traversed by the veins. At the border dark dots, in front of the border a shade. The distal line below the cell bent in, irregular. On the discocellular streaks; one basal line and 2 proximal lines lighter, 24 mm. Is said to originate from Petropolis in the Organ Mountains.

P. 698, line 6 from below. *Siseme hothurus* Berg differing from the other *Siseme* by exhibiting in the marginal area not the radiary striation, as *neurodes*, *pallas* etc., is said to originate from Argentina; it is not before me.

P. 700, line 28 from below, for „*Apodemia druryi* Edw. read „*duryi*“.

drucei. P. 701, „ 10 „ below. Insert here: **H. drucei** *Giacom.* Standing between *cisandina* and *chilensis*.

P. 707, „ 21 „ above, for „*glaucobithris*“ read „*glaucobrithis*“.

P. 708, line 14 from below. The animal described here as *Echenais micator* and figured by this name t. 138 h has proved to be a ♀-form of *Ech. alector* Btlr. (p. 707), at a minute examination. It deviates especially much from the ♂-form and seems, in the figured form, to be confined to Peru.

P. 712, line 2 from below, for *hesperium* read *hespericum*, and for *erythroicum* read *erythraicum*.

lenocinium. P. 713. Insert here: *Nymph. lenocinium* Schs. 22 mm. Described according to 1 ♂ from La Florida in Costa Rica. Wings white, forewing with a broad brown costal margin. At the transverse vein a fine dark streak and a fine postmedial line on vein 5; the traces of a small, blue-bordered spot in the cell and outwards at the costa; the inner edge of the dark marginal band dentate; a fine blue submarginal line, a similar one at the border itself. Hindwing at the base narrowly black, distal margin blackish-brown, the subterminal line like in the forewing; border and fringes white. — The diagnose does not mention to which species this butterfly is allied.

P. 717, line 5 from below, for *glaucoconia* read: *glaucoconia*.

P. 718, „ 12 „ above, for „♀ of the preceding species“ read: „*Tharops superba*-♀“.

9. Family: Lycaenidae.

The delimitation of this family is not difficult for the American forms either, if the characteristic of the *Lycaenidae* which are devoid of any real cleaning-paws is to be decisive. Thereby a contrast is effected with the *Danaomorphinae*, *Nymphalidae* and *Satyromorphinae*, in which both sexes, and with the *Erycinidae*, in which the ♂♂ exhibit the forefeet transformed into cleaning-paws *). The *Lycaenidae* are separated from the *Papilionidae* by such conspicuous differences of the habitus that not one word need to be said about them. In a similar manner the *Pieris* exhibit besides the remarkable peculiarity in the subcostal neuration of the forewings, a rise of the 3rd, 4th and 5th branches from a joint pedicle, whereas the *Lycaenidae* exhibit only a two-pronged bifurcation of the veins in the apex of the forewing, if not all the subcostal branches rise separately from one another. Another characteristic mark of the *Lycaenidae* are the bean-shaped outlines of the eyes being circular or slightly oval in the other day-butterflies.

So far about 900 to 1000 *Lycaenidae* have been described from America, less, therefore, than from the palearctic district in which many more names were distributed. But as the names of most of the American forms were allotted to well distinguished species, while those of most of the European forms were given to insignificant sub-forms or aberrative discolorations, the number of the American species is probably twice or thrice as large as that of the whole palearctic district. It has never occurred that an American species has been denominated by more than 20 different names as for instance the palearctic *Chrysophanus virgaureae*, *phlaeas* or *Lycaena icarus*. America, however, is inferior to the Indo-Australian fauna, regarding both the number of species and especially the variety of the genera of which there are more than 120 in the east; in America, however, but quite few. The Ethiopian region, however, is excelled by the American *Lycaenidae* as to the number of species. From Africa to the south of the Sahara, and from the islands belonging to it, we know about 6 to 700 *Lycaenidae*, one third of which belong to groups that have no allies in the American district, i. e. the *Lipteninae*. Such Lycaenid-groups, being to some degree isolated and characteristic of the special district like this subfamily or perhaps the *Liphyrini*, are not found in the American region; on the contrary, all the American species belong to such genera that are represented also in the Old World, with the sole exception of few species of the genus *Eumaeus* to which we shall revert later on.

In America itself the distribution is similar to that of the palearctic *Lycaenidae*; in the tropics there are considerably more species, though by no means in such great numbers as for instance the *Ithomiini* (the so-called Neotropids) in the equatorial districts, which disappear abruptly on reaching the northern or southern tropics. Not even in one of the Lycaenid-genera containing many more species, the tropics form the delimitation; except that the insignificant forms of the northern part of North America and the southern part of South America, being allied to the European forms, are replaced in tropical America by brightly coloured and variegated, often also very large *Lycaenidae*.

The geographical distribution of the *Lycaenidae*, which exhibits many striking peculiarities, is full of problems also in respect of American species. Some of them have analogs on the eastern hemisphere, just like in New Zealand and Australia there occur forms that have their nearest allies not in the interjacent India, but quite in the north (*Chrysophanus salustius*, *boldenarum*, the *Erebia*-like Satyrids *Argyrphenga* etc.); thus also the *Lycaenidae*, particularly the *Thecla*, grow, towards the southern point of South America, more and more similar, instead of dissimilar, to the North Americans. These resemblances are undoubtedly due to convergent symptoms, in which similar groups of animals react in a similar way upon the climate which naturally approximates in the extremest south to that of the northernmost region. By this, however, we cannot explain other symptoms, such as the occurrence of otherwise African genera on the high ridges of the Andes (genus *Cyclurius* Blt.). Such cases must involuntarily rouse the suspicion that these genera are no natural ones, since their homogeneousness was established upon criteria that are not to be understood as the symptom of alliance, but as fortuitous or also as convergencies.

Of certain palearctic habitats we know that sometimes an enormous number of specimens of *Lycaenidae* gather there, sometimes entirely of one species, often composed of different species. We have already called the readers' attention to the small water-courses of the Alps, where the alpine *Lycaena* sometimes gather in

*) In the ♂♂ of the *Lycaenidae* the forelegs are at any rate smaller than in the ♀♀ and they have a plain terminal member. Cf. Vol. I, p. 257.

such crowds that whole clouds of them fly up in front of the perambulator. I have recorded the immense number of *Polyommatus baeticus* in India and of the very small *Zizera* of which the air sometimes seems to glisten. I have never been able to observe an analogous occurrence of crowds of *Lycaenidae* in America. Even in Brazil abounding so greatly in butterflies I almost everywhere met *Lycaenidae* only quite sporadically; in some daily captures not one single *Lycaenid* is represented by more than 1 specimen, only sometimes a greater number of specimens met at wet places on the road.

Except the fact, also applicable to other faunae, that the large and brightly metallic species are exclusively tropical also in America, the north of the western hemisphere exhibits a distinct preponderance of the groups which are spread also over Europe and North Asia, viz. the genuine *Lycaena*, the *Chrysophanus* and those *Thecla* that approximate their European allies in shape and colour. These species, resembling our palearctic species, disappear in Mexico and do not occur anymore to the south of the Central Mexican deserts. Only on the ridges of the Cordilleras small alpine forms resembling exteriorly our *Zizera*, *Everes* and the north-oriental *Chilades* extend over the whole continent, joined in the extremest south again by *Lycaena*-like blue butterflies and *Zephyrus*-like *Thecla* in the same degree as the variegated, large, often also long-tailed *Thecla* of the American tropical zone disappear.

The uniformity of the *Lycaenidae* is much greater in America than it is in India or Africa. In the palearctic region 34 genera have been distinguished the existence of all of which may be distinctly asserted, although they have not been universally acknowledged. The Ethiopian district has 48 genera, while in the Indo-Australian there are even more than 100 genera. Chiefly for the sake of perspicuity, an attempt has been made also to separate the many hundreds of American *Thecla* in a great number of genera, but these attempts have proved to be impracticable. In these attempts the same principles have not been pursued as in systematizing the palearctic species, else the ascertainment would have been made that among the American *Thecla* distinct resemblances of some species are to be found to *Zephyrus*, *Callophrys*, *Tajuria* or similar genera, that even in *Thecla*-forms, such as *cypria*, *nobilis*, *marsyas*, *loxurina* much greater extravagances in the shape and colouring are exhibited than sometimes in palearctics of different genera. But we have nevertheless not yet succeeded in accomplishing a disintegration of the American genus *Thecla*, which would have been conclusive, so that this genus, with about 800 forms, remains one of the most difficult to survey.

The more the *Thecla* are preponderant in America, the more the *Lycaena* recede; but their colour, the intensive blue of the upper surface, seems there to have passed on to the *Thecla*. The upper surface being throughout dark-brown in European *Thecla*, in the palearctic *Zephyrus* sometimes even orange-yellow, is exhibited in America to be preponderantly a radiant metallic blue or golden-green, so that the exterior habitus shows counterparts of the palearctic *Arhopala* (*Th. hemon*), of the *Tajuria* (*Th. halesus*), of the *Lampides* (*Th. phydela*), of the *Horaga* (*Th. zaria*), of the *Cyaniris* (*Th. sito*), of the *Callophrys* (*Th. dumetorum*), of the *Satsuma* (*Th. henrici*) etc.

On the under surface the American *Lycaenidae*, in the north of the range, exhibit yet resemblances with the characteristic dotted eyespot-marking of most of our *Lycaena* which was looked at as an approximate reproduction of the stamina on the receptacles of blossoms abounding in honey. It may be connected with the habit of passing the night on the blossoms. Mostly, however, it is only a dull silhouette of the adornment with eye-spots, which we find in the Americans; only in *Lyc. acmon*, *daedalus*, *glaucon* and some others it grows more distinct; in America it scarcely attains the degree being usual in our more beautiful species, such as *Lyc. argus*, *icarus*, *arion*, *adonis*, *corydon* etc.

In spite of their great variability of the marking beneath, nearly all the *Thecla* exhibit the typical *Thecla*-marking consisting of a postmedian stripe and often also an antemedian stripe with an interjacent, small cell-end stripe. The anal eye-spot of the hindwing beneath being nearly always distinct in Indian *Theclini* and often even adorned with a metallic lustre, is of a much inferior importance in American species and, in many cases, it is not prominent at all. The real *Thecla*, as a rule, are not used to sleep on blossoms, but on the ground, on trunks or (mostly) in the bushes. Their under surface is accordingly often green like a leaf or adapted to a dry, withered or folded leaf.

Much more conspicuous than in the colouring, the extravagance of the American *Lycaenidae* is in the shape. This, however, always only refers to the wings; the body in all the species shows a conformity being found in scarcely any other family and, in the *Lycaenidae* themselves, also in no other fauna. In the *Nymphalidae* we have found sometimes long, thread-like antennae, sometimes short clubs; the palpi were sometimes inflated, sometimes prolonged like a nose or also short and pointed; the abdomen was in some cases long and thin as in a dragon-fly (as for instance in some *Heliconius*), then again it represented (in the *Anaca*) only a conic appendix to the excessively broad thorax, etc. In the *Lycaenidae*, however, a difference in size (usually not too great) is the only mark we can find in American species, whereas the *Liphyra* and *Allotinus* in India, the *Curetis* in Asia, the *Liptena* in Africa show that a certain variety in the structure of the body is not entirely

foreign to the *Lycaenidae* in other parts of the world. Solely the *Eumaeus* which we shall have to mention later on also in a biological respect, deviate in manifold respects also in the structure of the body.

The most conspicuous part of the wings are the hindwings, in which the formation of delicate, small tails in the anal region has sometimes degenerated into long, thin, soft filiform appendages. Particularly the *Thecla* of the *imperialis*-group exhibit these formations which appear even more loosely arranged than those of numerous Indian forms, such as the *Sithon* and their allies. The long, sword-like or sabre-shaped tails, as are found in so many Indians (e. g. *Loxura*), do not occur in a similar development in America. But the longer appendages to the hindwings of some species are so delicate and soft that they dangle to and fro at the least puff of the wind. It is strange that these fine formations do not suffer more from the flight which is impetuously swift in some of these long- and thinly-tailed species. Nor do these tails, on capturing the animals in the net, break off as easily as one might fancy, considering their fineness, and I repeatedly captured much-flown and otherwise damaged specimens of *Thecla imperialis* in which the delicate appendages were well preserved.

Another peculiarity in the shape of the hindwings of the American *Thecla* are the small anal lobes which, being situated proximally to the filiform tails, may be of a laciniiform or bossy shape. Like in many palearctic species, they are often so long that, in the resting butterfly, they reach down as far as below the anal end of the abdomen and would thereby be inconvenient, for which reason they are bent down rectangularly to the surface of the wings.

The proximal margin of the hindwings is mostly slightly bent in, but it may also be distorted to a deep indentation or notching. Exactly where, in the sitting butterfly, the apex of the abdomen rests on the support, there is in some species, such as *Thecla latraillei*, a strange indenture in the margin of the wing as if to render the sexual organs accessible to the copulation which organs, in encasing the abdomen, would otherwise be covered by the inner-marginal fold of the hindwings. The clasping-organs of the male, as much as is evident from the very scarce material examined so far, seem to be still more conformably built than in the *Erycinidae*; up to now the examinations of the clasping-organs have not yet yielded any surprising systematic results.

On the other hand, very many American *Lycaenidae* exhibit the scent-spots and male scales, which have already been profoundly studied in the European species. The former organs, serving according to one hypothesis for producing the scent, are found in very many *Theclini*, where they almost invariably are placed near the end of the forewing-cell and are exhibited as oval, more rarely circular, scale-pads of a red-yellow, brown or black colour, which are particularly bright and prominent in those species the upper surface of which exhibits a blue or golden-green metallic lustre which is absent in those scent-pads.

These pads exclusively occur in male specimens and are immediately noticeable for instance in *Thecla gemma*, *sista*, *aurora* (t. 151 a) and other *Thecla*, as well as in European *Theclini* (*Callophrys rubi* etc.). They consist, however, of scales showing no essential structural differences from the normal wing-scales, nor has there been, according to COURVOISIER, a proof produced of their function of producing the scent, though one cannot fail to recognize that a function of the male sexual activity is due to them.

We must distinguish from these the modified male-scales considered as real androconia and distributed over the upper surface of the wings, the structure of which was exhaustively investigated by KÖHLER 20 years ago and recently by COURVOISIER. They are sometimes apparently irregularly scattered across the surface of the wings, but mostly arranged to zones, stripes and bands which sometimes show a certain relationship to the shape and marking of the wings. They were sometimes found to be of the shape of a tennis-racket (WATSON), or sometimes utricular or vesicular (ANTHONY), and ILLIG discovered at the base of their footstalk glandular cells which he presumes to discharge their secretions over the scale thus representing in a certain manner a bowl for the evaporation and production of the scent. This agrees well with what COURVOISIER ascertained later on viz. that the shape of these scales is not that of a balloon, but more of a spoon.

On this occasion, the latter investigator also discovered the systematic applicability of these androconia. He evidenced for quite a number of species a characteristic formation adherent to the species. He was able to follow up the same forms of scales through a great number of aberrations, local forms and geographical races. In most cases all the forms belonging to one total species showed the same structure of the male scales, and numerous changes in the homogeneity of subspecies and local races were proposed by reason of these investigations. The finer structure exhibited a steady number of the separate species of longitudinal ribs extending over a finely reticular surface. The transverse meshes, at the junctions show verrucous knots forming again characteristic figures, so that COURVOISIER comes to the conclusion that these scales are at least just as fit for specific differentiations as the clasping-organs.

Opinions differ greatly as to the intrinsic properties of these scales. They have been looked at as malformations of normal scales, or also as air-bellows in order to assist the flying-activity. KENNEL thinks that originally both sexes had been provided with such scales, but that these had then been lost by the females.

Against their function as scent-generators it was assigned that the frictional movements which were to generate the scent, were performed also by the females and by species in which both sexes were without the scent-pads as well as male scales, so that one must consider these frictional movements to be more the expression of comfort than that of sexual activity. But the strange fact that the *Lycaenini* in which the male scales are particularly well developed, are devoid of the scent-pads, and that, on the other hand, the *Thecla*, with distinct scent-spots, are apparently entirely without the androconia scattered over the surface of the wings, makes us anyhow think that both the formations replace each other. The striking fact remains that in several *Chrysophanini* that were examined neither pads nor male scales were found.

Most peculiar is a gibbous distortion exhibited by the forewing of some species at its costal margin. Shortly before the cell-end the costa grows into a linguiform continuation mostly matching well the scheme of markings beneath, as for instance in *Th. gibberosa*, *tomlinsoni* and some other species. There the under surface shows dark transverse bands on a white ground, and as if they would have to be prolonged beyond the surface of the wings, a lobate appendage extends beyond the margin of the wings, at their discharging-place at the costa. The purpose of this quaint formation is not to be ascertained, unless the biology of the different species be exactly known; the obvious presumption that room had to be made here for a greatly expanded scent-spot is not conclusive, since this appendage is not less developed in females than it is in males.

As to the variation, the American *Lycaenidae* are generally speaking most constant in their formation. Certainly in some forms, being to-day dealt with as separate species, it may turn out on getting knowledge of their biology and which as yet has been ascertained in but very few tropical species, that they are seasonal- or local-dimorphous forms of a species. Some species seem to be most peculiarly variable, since they are able to transform themselves from red into blue, in a similar way as e. g. in the palearctic *Chrysophanus alciphron* northern specimens are covered with a bright bluish violet, southern ones, however, of a glaring yellowish-red colour. It is a striking fact, however, that, while in the *Chrysophanus* the heat of the south takes away the violettish-blue cover, so that the fiery red shines forth unsubdued, in the American *Thecla loxurina*, according to A. H. FASSL's observations, the alpine climate of the Cordilleras favours the pure red, and the hot-house-heat of the lower districts changes the red into blue.

In many cases of the American *Lycaenidae* we may speak of a general adaptation of a brown under surface in species resting on the ground, of a green under surface in those resting in the dense foliage; but we do not notice an extremely minute copy of stones on the road, of tree-blossoms or of accurately ribbed leaves as we find it so much in *Nymphalidae*, *Satyridae*, and also in very many night-butterflies. The American *Lycaenidae* mostly rest hidden, often beneath the leaves or at the leaf-stalk, often they creep very far into the interior of the bushes, so that the enemies lying in wait in open spaces do not get much sight of them. Their tactic of escaping them consists in an intense concealment or slipping away (so-called „slippers“), during the swarming-time, however, in a very well developed flying-power to which I shall revert later on. A disguising by borrowed attires does not occur at all in the real American *Lycaenidae*; only one genus — *Eumaeus* being somewhat problematic in its position — shows a resemblance with patented butterflies of its range. The most remarkable resemblance of *Eumaeus atala* or *minyas* with the homochromous *Actinote neleus* is the more amazing, as beside the black, metallic-reflecting wings also the vermilion abdomen serves to complete the mimicry. From innumerable examples of other groups we know that just the mimetic adaptation of glaringly red places of the body cannot be so plain as spots or markings on the surface of the wings, because otherwise very well hit-off copies (e. g. the ♀ of *Papilio rhetenor*) are not able to imitate the red on the body of their model (*Papilio semperi*) and are thereby forced to transfer it on the wings in the shape of a red stripe being placed close to the body (which is of course not to be noticed in the living animal, since *rhetenor* is used to cover the red stripes of the wings partly over the body). It is therefore most amazing that in the family of the *Lycaenidae* exhibiting otherwise, except Africa, no mimicry and a very little developed adaptation, this high degree of mimicry is found in this one genus.

Another very striking mark in this genus just mentioned are the relations to the Erycinid-genus *Hades* with which it exhibits an extensive biological correspondance. Its gregarious occurrence at certain, mostly damp localities, its habitus, colour, size and way of flying, the same patria (Central America and the northernmost parts of South America) and the joint swarming-places with the likewise gregariously occurring *Morpheus ehrenbergii* are too evident to be regarded as a mere accidental coincidence. In the *Hades* and *Morpheus* the abdomen is certainly not red itself, but like in the mimicry-case already mentioned of *Papilio* (s. s.) *rhetenor* and *Papilio* (*Pharmacophagus*) *semperi* from the Philippines the red is attached directly next to the body on the under surface of the hindwings, somewhat proximally to the place where also the West-Indian *Eumaeus atala* Poey exhibits a red spot.

Also in the anatomy the *Eumaeus* differ considerably from all the other *Lycaenidae*. The transverse vein of the hindwing, being in the *Thecla* mostly quite faint, sometimes vanished to scarcely noticeable traces, is so strong that it forms a distinct termination of the discocellular. The first subcostal vein rises separately from the upper radial vein, whereas on the forewing the 3rd and 4th subcostal veins have a long joint footstalk. Finally, also the female forefeet are better developed than in most of the *Thecla*, and we may, therefore, see in the *Eumaeus* a similar transitional joint to the *Erycinidae*, as in the Indian *Curetis* which also deviate in many ways from the Lycaenid tribe. Like in many *Erycinidae*, we have also in the larvae of *Curetis* an organ being unexplained in its closer functions, which is not placed at the neck as in the American *Erycinidae*, but consists of rotatory whirling threads serving perhaps for the same purposes as the neck-organ of the Erycinid larvae, i. e. for protection.

The eggs of the *Lycaenidae* are cake- or turban-shaped, varying greatly in height and size, but are mostly conformable in shape. The surface is usually distinctly grained, less divided into areas or cells, the micropyle often drawn in.

We as yet know extremely little of the American — particularly South American — Lycaenid larvae. The species belonging here and being for the greatest part of the genus *Thecla* have presumably mostly tree-larvae, and it is, therefore, not astonishing that hardly anything is known of the early stages which are even at the habitat itself difficult to ascertain. The most we know of the North Americans of many of which already *Boisduval* and *Leconte* supplied the life-history (1833). Later on, in the sixties of the last century, particularly *Morris* and *Saunders* have acquainted us with many American Lycaenid-larvae. Still later on, W. H. EDWARDS, SCUDDER, PACKARD, FLETCHER, MISS MIDDLETON and others, published (mostly in the „Canadian Entomologist“) the life-histories of many species; but it is certainly not even the twentieth part of the American *Lycaenidae* with whose early stages we are familiar. On the whole it follows therefrom that, although the shape of American *Lycaenidae* seems not to deviate essentially from that of their palearctic representatives, still the habits, particularly the nutrition, are remarkable in different respects. Some *Thecla*-larvae feed from plants of families that are otherwise not known as the nourishment of *Lycaenidae*, such as the cotton plant (*Gossypium*) and the sarsaparilla (*Smilax*) belonging to the monocotyledons; *Thecla nippon* lives on conifers on which we do not meet with any Lycaenid-larvae in the Old World.

Most peculiar, however, is the life-history of *Feniseca tarquinius* being common in some parts of North America, the larvae of which live on plant-lice. But if HENRY EDWARDS says that this species is the only species among all the North American butterflies that has a carnivorous larva, he is only correct in as much as the other larvae of day-butterflies known from North America are under normal circumstances phytophagans. We know from CARLOS BERG that the larva of *Pyrameis carye* living likewise in North America becomes carnivorous and even cannibal in Patagonia, at the frontier of the region governed by phanerogamia. By its nutrition from plant-lice, the American genus *Feniseca* forms to a certain degree a parallel with the Indian *Gerydini* (cf. Vol. IX, p. 804) which have likewise entirely given up being phytophagans.

The large and brightly metallic-coloured *Lycaenidae* of America are real children of the sun. As soon as a cloud covers the sun, they disappear, i. e. they slip into the midst of the densest bushes, whereas in the intense sunshine, they cheerfully play round the twig-ends of large trees and the tops of bushes in the very same way as their European allies are used to do. The males then post themselves at the end of a twig projecting beyond the skirts of the woods, their heads always turned away from the woods and towards the open space, lying in wait for the females wandering restlessly along the skirts of the woods, until a male accompanies them. At their favourite haunts, being particularly the ends of forest-corners, the turnings of roads or also solitary bushes, we may see, almost invariably in South America, during summer in North America, some *Thecla* bustling about. On settling down the wings are always tightly closed, only some smaller species sometimes open them half, similar to our *Lycaena*, as for instance the species allied to *Th. elongata* flying more in the grass than on the bushes.

Most of the American *Lycaenidae* do not love flowers, except some blossoms abounding in honey, particularly umbels and tree-blossoms which are often visited by them. Nor do the American *Lycaenidae* frequently come to the bait, which is the more remarkable since some *Thecla*, such as *Th. ellida* and their allies nearly always fly near the trunks of trees the dripping sap of which, as soon as they exhibit luxuriant saccharomyces, exerts a great attraction upon most of the species of butterflies which we know as favourite visitors of the bait, such as *Catocalinae*, *Agrotis* etc. It seems, however, as if the *Thecla* were hunting on the trees more for certain lichens or algae than for the dripping sap, or as if they were swarming in order to discover the other sex; certainly the baiting for *Lycaenidae*, at least with the means having been used hitherto, is not successful.

On the other hand, the American *Lycaenidae* often and preferably come frequently to the water. The large, magnificent species, such as *Thecla regalis* and *imperialis* I saw, as soon as the morning-sun began to send down its hot rays into the open spaces in the woods, drinking the dew-drops from the leaves of the bushes. I never observed these large, magnificent forms coming down to the ground, in order to drink on the road; they seem persistently to remain in an altitude of about 2 or 3 m, so that I concluded that their larvae exclusively live on trees. I have already mentioned the gathering of *Lycaenidae* round watercourses being well-nigh typical for some mountain-slopes of the palearctic region, but I was not able to find a parallel case in America, although the *Eumaeus* are said to swarm in big crowds above the flooded surface of swampy fir-pine-woods, but to my knowledge nobody has ever reported from America a similar occurrence as for instance at the southern end of India proper, where the *Zizera*-species are whirling along above the ground in such crowds that the air seems to sparkle with them.

A most peculiar symptom is the habit of many *Thecla* of descending to the ground, at certain hours of the day, and of resting in the midst of the dust of the roads and highways. Wherever the desolate grassy plains of the pampas or prairies are interrupted by bushes or little woods, there are from time to time *Thecla* to be found resting on the sunny road, with their wings closed and without drinking. These are species that are extremely rarely met with at other occasions, and whoever has the chance of passing such places on the road at such an hour, may sometimes capture in a few hours dozens of *Lycaenidae* that are otherwise hardly obtainable. The same symptom I have observed in Germany in *Thecla w-album* being otherwise not common there, which I but once met with in great numbers, but which I otherwise discovered quite singly, some years not at all. The butterflies quite suddenly, from the tops of the trees, flew down to the highroad in the high dust of which they settled down. As their feet were not able to gain a footing in the fine dust, they sometimes tumbled down and remained lying on the side or made only faint attempts to raise themselves again.

The enemies of the American *Lycaenidae* presumably mostly consist in amphibia for the *Lycaena*, in reptiles for the *Thecla*. From the former they are probably protected by an ant-guard, from the latter not. The Indian *Lycaenidae* are known to be strictly guarded and fetched by the ants into their nests for the sake of their pupation; in doing so, the larvae were in due form escorted by the ants. The groups to which these palearctic species belong, have no representatives in America; some species approximating the species known from the Old World as the friends of ants, such as *Lycaena glaucon* etc. may have their larvae (not yet explored in their habits) living in symbiosis also in America. These relations, however, are very difficult to ascertain, and, for instance, we even do not know of some species which we have before us in Europe every summer, such as *Lyc. arion*, whether they pass their last larval weeks in the nests of ants or not. Ants that are a good hand in taking care of larvae, have also become known from Tropical America; it is, therefore, very likely that symbiosis with Lycaenid-larvae occurs there, too.

The flight of the American *Lycaenidae* is mostly nimble and easy, vivid, irregular, but only rarely as rapid as it is seen in some palearctic genera (e. g. *Polyommatus baeticus*). The larger butterflies of *Thecla* mostly only fly for a short distance, often only from one leaf to another. But on the other hand, there are groups, such as that of the *Th. leucogyna* and *phaea*, which are scarcely ever seen at rest, but always flying restlessly in the sun along the broad roads in the woods.

The pupae of the American *Lycaenidae* do not deviate considerably in the habitus from their palearctic allies. They resemble minute fruits, being of the shape of beans or buds and mostly fixed with the ventral surface on a petiole or twig. Their colour is mostly a subdued greenish or brown, some show a face-like figure on their dorsal surface, which is said to resemble a monkey's head in the genus *Feniseca*, something like in the palearctic genus *Spalgis*.

I. Group: Theclini.

1. Genus: **Eumaeus** Hbn.

This genus forming the transition to several *Erycinidae*, according to many examinations, is a real Lycaenid genus. The tarsi of the male forelegs are annexed to a cylindrical joint densely set with spines. The anterior tibiae, in their distal half, are likewise spinous and exhibit 2 longer spines at the tarsal end. At the proximal end of the median tibiae and at the distal end of the femur there are hair-spots. In the female all the 5 tarsal joints, inclusive of the distal end of the tibiae, exhibit strong spines, the terminal joint being as long as the 3rd and 4th together. The vigorous palpi are long and slender, the terminal joint in the ♀ longer than in the ♂. At the antennae we notice spines interspersed between the scaled cover. The eyes are almost naked, exhibiting only quite few, thinly scattered hairs. On the forewing the cell is narrow, before the cell-end there rise 2 subcostal veins, the upper discocellular is absent. On the hindwing the costal half of the cell is much shorter than the median half; the lower discocellular forms an acute angle with the median.

Further particulars referring to this genus containing 3 large, imposing species are to be found in the General Topics.

E. debora Hbn. (146 a) is the largest representative of the genus, above deep velvety-black with *dehora*. green, metallic, submarginal cuneiform spots, which are on the forewings longer, on the hindwings shorter and more triangular; metallic-blue stripes are found yet subcostally, in the cell and along the submedian. Beneath unmistakable by the numerous greenish-golden spots, which are silvery-blue in fresh specimens as in the figured ♂. — The carmine, black-belted larva lives gregariously on an *Amaryllis* standing in the water. The butterfly flies in Mexico and Guatemala.

E. minyas Hbn. (= *toxea* Godt.) (146 a, b) is smaller, the forewing with a blue, black-veined disc being *minyas*. of a very variable extent, the hindwing with golden-green, small cuneiform spots in front of the margin. Abdomen beneath orange-red. Widely distributed and common from the south-western part of Texas to Brazil. — We introduce the very imposing and extensively lustrous-blue Costa Rica-form by the name of: **costaricensis** form. *costaricensis*. *nov.* (146 b). — On the contrary, the more southern specimens from the Amazon etc. have particularly the ♀ above almost without any green at all; they may be named **brasiliensis** form. *nov.* *brasiliensis*.

E. atala Poey (= *toxea* Gray nec Godt.) (146 b; c as *toxea*) is smaller and duller, the hindwings nearly *atala*. entirely black with smaller, more blue marginal spots. Beneath the silvery-green macular bands of the hindwings are developed more proximally, costally more bent, the red inner-marginal spot mostly larger. The extension of the blue above also varies here greatly in the different specimens. From Florida and Cuba.

2. Genus: **Theorema** Hew.

Neuration almost like in *dehora*, but the cell of the forewing is somewhat broader, the 1st subcostal vein placed nearer to the base. The hindwing exhibits a small tail at the lower median-vein. In the ♂ the forelegs are not so very spinous.

Th. eumenia Hew. (♀ = *titania* Strecker) (146 b, c) is a magnificent species, the ♂ above of a *eumenia*. radiant peacock-blue, warming into green towards the margin, with a broadly black costal area of the hindwing; the ♀ is black, on the forewing with a bluish-green submarginal band and a white apex, on the hindwing with greenish-golden marginal spots. Beneath the dull-black hindwings exhibit 4 greenish-silvery macular rows in front of the border, the ♂ an opalescent blue stripe in the cell of the forewing and between the median veins. Known from Guatemala, Nicaragua, Costa Rica, Panama, and Colombia, but so far everywhere extremely rare.

Th. dysmenia spec. nov. (153 a) resembles above somewhat the *E. debora*; velvety-black, towards *dysmenia*. the margin with an indigo-blue lustre, on all the wings with submarginal, greenish-blue silvery spots receding somewhat at the apex of the forewing. Beneath dull-black with darker veins and a narrow, greyish-white distal margin growing broader towards the apex on the forewing. The ♂ is not yet known and is presumably above more extensively blue. Described according to a ♀ from the Upper Rio Negro (Colombia) from the Coll. FASSL.

3. Genus: **Trichonis** Hew.

Robustly built, head large, eyes naked. Costal margin of the forewings at the base strongly convex, distal margin uniformly rounded, proximal margin of the forewings in both sexes very convex, covering a polished spot of the costal half of the hindwing. On the forewing the subcostal is 2-branched. Hindwings round, with a short cell and a very convex costal margin.

T. theanus Cr. (146 b) is above and beneath light greenish-blue, above with a black distal margin; *theanus*. the polished spot is reddish-brown, so is the inner-marginal part of the forewing beneath, as far as it is covered by the hindwing. This quite uncommonly rare species seems to be known only from Guiana.

4. Genus: **Thecla** F.

A multiform genus of very small to medium-sized butterflies, the chief mark by which they are distinguished from the other genera being the more or less produced, often indented, pointed or rounded anal angle of the hindwing. Another characteristic is the development of the tails found in most of the species. In case there is only one tail, it is situated at the lower median vein and appears only in very rare cases as a direct prolongation of this vein, but is much rather placed mostly nearly rectangularly to it in the direction of the anterior angle, being, however, sloping upwards close behind its rise, so that it nevertheless retains the direction of the vein. If there is a second tail, its place is at the upper median vein and it is smaller.

The main characteristics regarding the general exterior, the habits and so on has already been told in the Preface (p. 740 ff.). According to our present knowledge it is not yet possible to classify the genus comprising more than 800 described species and being certainly not to be delimited uniformly, according to definite principles. Whether the method of the secondary sexual characteristic marks already proposed by others and continued by COURVOISIER, will attain its object, seems still to be doubtful to us. The scent organs, being a somewhat relatively recent discovery, are easily influenced and variable and are often present

or absent in one and the same species (e. g. *Th. irus*); they are, therefore, in our opinion unable to comply with the development of the race which we would consider to be obviously the most correct method of division. This is proved, for instance, by very remote and certainly not in the least allied groups exhibiting entirely convergently developed scent-spots; on the other hand, closely allied groups would undoubtedly be inserted in remote groups.

Best to make use of the affinities of the tribe and the most steady and oldest character is by all means the principle of the marking of the under surface which repeats itself again and again in long series. In order to arrange somehow the chaos of species, we therefore thought it to be the most correct way and, at the same time, the most facilitating for the searching diagnoser, to undertake, according to this plan, a division into 120 groups corresponding substantially to the groups assumed by GODMAN and SALVIN in their *Biologia*. Certainly the division must be somewhat altered by including North and South America, whereby a great number of new elements are added.

Many attempts have already been made to divide the *Thecla* into genera according to the most various principles, as for instance by HÜBNER, SCUDDER, KAYE according to the shape of the wings, the influencing of the veins by the scent-organs, the number of the tails etc., but neither of them is entirely satisfactory. Many of these denominations of subgenera coincide with certain names of our groups and may then be applied so; conformably to this we have made notes to them in the respective groups. Other names, however, must be split into various groups, as for instance the genus *Eupsyche* Scudder containing the species *m-album*, *telea*, *martialis*, *hugon* and *juda*, species which we were forced to place in just as many different groups and which, in a philogenetic respect, have certainly very little in common with each other.

One of the greatest difficulties was offered by the fact that many small and insignificant, but also some remarkable species are partly extremely rare and were often described according to single specimens some of which have never been discovered anymore since; many of the types cannot be found, so that several species are no more to be identified. We have mostly placed such cases at the end of groups to which they are presumably allied.

1. Imperialis-Group (*Theritas* Hbn.).

- imperialis.* **Th. imperialis** Cr. (= *venus* F., ? *actaeon* F.) (146 c) is above of a dazzling metallic greenish-blue, on the forewings with a broad black apex and in the ♂ with a blackish-brown scent-spot at the cell-end and behind it, which is parted by the transverse vein and is more red-brown in the posterior half. The ♀ is somewhat duller blue. Under surface golden-green, on the hindwings with a fine black transverse striation, without any distinct transverse lines; only at the anal angle short beginnings are noticeable. — In the form **ducalis** *Dbl.* (♀ = *oakesii* *Butl.*) (146 c) the disc of the hindwing is of a metallic carmine colour. The species is widely distributed from Nicaragua, Panama, Colombia, Guiana, Brazil to South Peru.
- cypria.* **Th. cypria** Hbn. (146 d) is above more green than the preceding, beneath with a broad, black, proximally whitebordered transverse-stripe on the hindwing, bending outwards below the cell. — The name of *paphia.* **paphia** *Fldr.* may, according to the figure, be maintained for the specimens with a fiery copper-red to carmine disc of the hindwing. From Mexico through the whole of Central America to Colombia.
- tuneta.* **Th. tuneta** *Hew.* (146 d) has broader, shorter wings than the preceding and the transverse stripe of the hindwing forms a regular, outwards concave bow shortly before the anal angle, bending then round almost rectangularly to the proximal margin. The scent-spot of the ♂ is small and lies behind the cell. Colombia, *splendor.* Brazil. — **splendor** *Drc.* (146 d) is probably only a form of this species with a submarginal dark transverse band on the forewing beneath, being also indicated on the hindwing. Described according to 1 specimen from Colombia.

2. Gabriela-Group.

- coronata.* **Th. coronata** *Hew.* (146 d, e) rather forms a group for itself by the forehead being in the ♂ crowned with a golden-lustrous cone. Above metallic-blue, the ♂ without any red anal spots which are very large and double in the ♀. On the golden-green under surface the black transverse band is proximally bordered by a light grey and touches the red band on the hindwing. From Guatemala to Colombia and Ecuador.
- ganymedes.* **Th. ganymedes** Cr. (= *teresina* *Hew.*) (146 e, f as *teresina*) is above blue with a narrow black distal margin, being faded towards the surface of the wings, in the ♂ without the scent-spot; beneath golden-green, in the proximal half of the forewing blue; the inner broad black, distally white-bordered transverse stripe of the forewing extends from the costal margin to the upper median vein; on the hindwings the black and the red bands are about of the same width, the latter, however, grows somewhat broader beneath the subcostal vein and strangles here somewhat the black one; in an anal direction the red band usually exhibits no black spots. Widely distributed from Mexico to Colombia.

Th. gabriela *Cr.* (= *gabrielis* *Godt.*) (146 f) is very similar; on the under surface of the forewing the *gabriela*, proximal transverse stripe extends down as far as below the lower median vein, on the hindwing the broad black transverse band forms an oval and, beneath the subcostal vein, it is broad and not strangulated, forming a W at the proximal angle; the red band is very broad on both surfaces, but not sharply defined by white. Colombia, Amazon.

Th. sponsa *Mschlr.* differs from *gabriela* above by a larger, carmine anal-angle-spot of the hindwing, *sponsa*, beneath by the red spot reaching from the proximal margin only to the upper median vein, in which there are 2 black spots. Surinam.

Th. batesii *Hew.* (146 f) likewise greatly resembles *gabriela*, though it is easily distinguishable by the *batesii*, under surface of the hindwings, exhibiting only a rather uniformly broad, red-brown band divided by a white line, and forms only a V, not a W, at the proximal angle. Brazil.

Th. sumptuosa *Drc.* (= *gabriela* *Godt.*) (146 f) is above separable by the large, silky-grey scent-spot *sumptuosa*, of the forewing, being situated below and behind the cell. On the under surface of the hindwing there is only an oval, red-brown band being distally bordered by a white line and behind it by a black line. Brazil (Espírito Santo, São Paulo).

Th. candidus *Drc.* (147 a) is very similar and perhaps only a form of the preceding species with a *candidus*, scent-spot being taperingly prolonged towards the base below the cell. Beneath of a magnificent bluish-green with very distinct markings, the black being increased on the forewings, and like in *sponsa*, there is only some red with black spots therein towards the anal angle on the hindwing. From Colombia (Muzo).

Th. ornatix *Drc.* (146 f) has beside the scent-spot of the preceding yet a second one above the *ornatix*, median in the cell; beneath likewise very similar to *sponsa*. Described from Brit. Guiana.

Th. regalis *Cr.* (= *endymion* *F.*) (146 e) differs greatly from the preceding and approximates *coronata* *regalis*, the most, from which it differs beneath by the transverse lines being not distally but proximally bordered by whitish-grey; the one on the hindwing does not quite touch the red transverse band, but it is separated from it by the green ground-colour. Above the blue grows somewhat more greenish and there are red anal spots in both sexes. The black margin of the wings is comparatively broad and proximally not faded, but sharply defined. Occurs most widely distributed from Mexico to the Amazon.

3. Tagyra-Group.

Th. tagyra *Hew.* (147 b) is a very strange animal, above blue with a silky-grey sexual-spot of *tagyra*, varying size, beneath likewise blue with black, distinct transverse bands. — **floralia** *Drc.* (147 b) has been raised *floralia*, to a species, but the only difference is the prolonged ♂-spot; the latter, however, varies (as in some other species) sometimes from one specimen to another, so that it cannot be a specific mark of distinction. Described from the Amazon district, also before me in a couple being beneath of a somewhat lighter turquoise-blue with narrower black bands, from the Rio Songo (FASSL).

4. Episcopalis-Group.

Th. episcopalis *Fassl* (153 a). Very different from all the other species known. Above of a radiant *episcopalis*, golden-green with narrow black margins and a broader apex, beneath on the forewings metallic-blue, towards the margin warming into a golden-green; hindwings green with 3 black transverse bands being convergent towards the proximal angle and in an oblique light gleaming in a magnificent peacock-blue. Discovered by A. H. FASSL in the West Colombian Andes at an altitude of 2000 m (Rio Aguaca Valley), where the species was flying round the tops of trees in the morning-sun.

5. Nobilis-Group.

Th. nobilis *H.-Schöff.* (= *bimaculata* *Mschlr.*) (147 a ♀, 153 a ♂). This group, strictly speaking, *nobilis*, likewise contains only one representative, if one does not want to place the species in the *gabriela*-group. The ♂ is greatly distinguished by the fact that, beside the roundish grey cell-stigma, there is another oblong black spot at the end of the submedian, which, however, does not contain any scent-scales. Beneath similar to the *gabriela*-group with a very broad red band of the hindwing. From Guatemala to Colombia and Guiana.

Th. telemus *Cr.* (= *antinous* *Fldr.*) (147 a, b) we include here for the sake of exterior resemblances. *telemus*, ♂ above lustrous sky-blue with an extremely fine black border; the tails are also blue. Stigma greyish-brown, behind the cell-end; ♀ of a more subdued blue, with broad, blackish-brown margins. Under surface green with an extremely variable marking and colouring, so that there is no distinct delimitation to **antinous** *Fldr.* (147 b). *antinous*. The ♂ is sometimes without any red at all, particularly in southern specimens, so that there is a broad, sky-

blue marginal band, sometimes there is a large red spot which mostly grows very extensive in the ♀. Very common and widely distributed from Central America to Colombia, Guiana and the Amazon.

6. *Venulius*-Group (*Paiwarria* Kaye).

renulius. **Th. *venulius* Cr.** (153 a). Above lustreless greyish-blue, beneath likewise light-blue with 3 submarginal blackish bands, the proximal one mostly red-brown; between the median veins of the hindwings there is in the middle band a black spot being above bordered by orange. Widely distributed, but apparently very rare from Guiana to Bolivia (Rio Songo).

7. *Satyroides*-Group (*Macusia* Kaye).

satyroides. **Th. *satyroides* Hew.** (147 c). In the species of this group the broad costal space of the forewings is covered with long hairy scales directed downward. ♂ above dull violettish-blue, ♀ brown, hindwing with an orange-brown anal eye-spot, beneath very similar to *venulius*, ♂ more greyish-blue, ♀ brown. Amazon, Rio, Sta. Catharina.

temathea. **Th. *temathea* Hew.** (147 c) is above the same, beneath, however, the hindwing exhibits another transverse band nearer to the base. Amazon.

latreillei. **Th. *latreillei* Hew.** (147 c) we include here, because the costal margin of the forewings exhibits the same hairy covering and also beneath the scheme of markings is similar. The shape of the wings is very characteristic by the stunted apex of the forewing and the deep indenture at the proximal margin of the hindwing above the anal lobe. The tails are much broader than in the preceding. Above metallic dark blue, beneath brown with more intensely red-brown transverse bands and rows of lunular spots. Brazil (São Paulo, Sta. Catharina, Pt. Alegre) to Paraguay.

8. *Assula*-Group.

assula. **Th. *assula* spec. nov.** (153 a) is a very peculiar animal without any closer relations to other groups. By the deep indenture above the very well developed anal lobe and the slightly stunted apex of the forewing its shape resembles *latreillei*, but the hindwings exhibit only a broad, almost spoon-shaped tail. Above unicolorously deep purple-brown, the anal lobe and an indistinct marginal line on the forewings towards the hinder-angle deep chestnut-red; the base of the fringes particularly at the anal lobe and some scales in the centre of the apex of the tail bluish-white. Beneath the forewings are brown, towards the apex dusted in white with a lighter line beyond the centre as far as the lower median vein. Hindwing of a deeper blackish-brown; from the centre of the costal margin proceeds a lighter stripe ending directly in the tail with a distally concave bend and being distally strewn with single white scales and being united in front of the border with one row each of lighter lunular spots coming from both sides; in the anal lobe and in the cell-spaces between the median veins there are carmine spots standing behind; at the proximal margin some more, irregular, white-scaled markings. The base of the fringes white, more distinct than above. Described according to 2 ♀♀ from Colombia, a fresh one from Bogotá, a much-flown one without tails from the Monte Socorro, from the Coll. FASSL.

9. *Marsyas*-Group.

marsyas. **Th. *marsyas* L.** (147 d) is a well-known, large species with an almost falciform apex of the forewing which, however, varies in its development, above beautifully sky-blue with a broad, jet-black apex of the forewing. Beneath lilac-grey, on the hindwings towards the proximal angle white strewn with mildew-green scales, with black spots and linear markings which are well reproduced by our figure. — ***cybele* Godm. & Salv.** is an insignificant side-form with distally deeper blue wings. From Panama to South Brazil.

damo. **Th. *damo* Drc.** (147 d) is a species hardly separable from the former. It is above lighter and more silvery-blue than *marsyas* and is without the broad black apex of the forewing. In its size and the development of the falciform apex of the forewing it is just as variable as the preceding. — ***dorcas* Drc.** is a Peruvian form with distally deeper blue forewings, and in the ♀ the margins of the wings are narrower blackish-brown. The species extends in the north as far as Mexico, to the south as far as Ecuador; it very often flies at the skirts of the woods, but it is difficult to capture, as it flies very high.

10. *Theocritus*-Group (*Mithras* Hbn.).

theocritus. **Th. *theocritus* F.** (= *nepia* Godm. & Salv.) (147 e as *nepia*) is a very unique species, above almost silvery, the distal half of the forewing blackish-brown; the ♀ is somewhat bluer. Under surface blackish-brown with rows of metallic-green spots. Distributed from Mexico to Colombia (Muzo).

Th. augustula Ky. (= *augustinus* Btlr. & Drc.) (147 e) is very similar beneath, but the proximal margin of the forewings is brown, in *theocritus* silvery blue. The ground-colour above is a deep blue, with metallic green spots near the anal angle. From Mexico to Panama.

Th. monica Hew. (147 g) is above somewhat more greenish than the preceding with a less extensively black apex of the forewing; beneath duller greyish-brown with a light, partly white-chequered apical part and smaller indistinct greenish spots which are arranged almost like in *lisus* (148 a). The ♂-hindwings exhibit beneath yellowish-white scent-scales hidden in a hairy fold below the median. Venezuela, Colombia.

Th. gispa Hew. (147 e) probably also belongs into this group. It is larger, above metallic-blue with only narrow black margins, in the ♂ with a discal spot at the cell-end. Beneath dark-brown, the inner-marginal half of the forewing of a brilliant silvery-blue, the hindwing in the distal half green, clouded in brown, traversed by a brown band, veins broadly brown. Apparently very rare. Amazon.

Th. hamila Jones (147 f) is much smaller than the preceding, otherwise very closely allied to it with a large scent-spot. Beneath very easily recognizable by the sooty-black colour covering the whole wings, which is, however, much too little expressed in the figure. Castro (Paraná), Rio Grande do Sul, Sa. Catharina.

Th. crines Drc. (147 e, f) is very similar, the wings a little broader, above with a more intense metallic lustre, beneath the blackish-brown ground-colour in the basal third of both wings densely strewn with emerald-green scales and in front of the distal margin of the hindwing there stand 3 or 4 more or less complete rows of magnificently metallic-green lunular spots. The ♀ is of a much duller blue, above with very broad brown margins. So far it seems only to have been found in Colombia.

11. Hemon-Group.

Th. lisus Stoll (= *hisbon* Godm. & Salv.) (148 a, 147 f) is above metallic ultramarine-blue without a scent-spot with narrow black margins and a darkened apex, in the ♀ more greenish-blue with very broad brown margins. The under surface is very variable, brown to black with 3 whitish to green, undulated lines in front of the distal margin of the hindwing and an angularly broken row of small, bluish-white or green spots in the disc, the uppermost of which is black-pupilled outside at the costal margin. The differences mentioned by GODMAN as to his *hisbon* are merely individual. Wide-spread and everywhere common from Guatemala to Colombia and Bolivia.

Th. viresco Drc. (153 b) differs by a more compact structure, a greener upper surface with somewhat broader margins and the opalescent green disc of the forewing beneath. From Brazil and Colombia (Rio Negro). — **photeinos** Drc. (147 f), differing only above and beneath by a lustrous-blue colour is probably scarcely a different species. From Brit. Guiana.

Th. orsina Hew. (148 a) I do not know: it is presumably scarcely specifically separable from *lisus*; it is said to differ by longer hindwings and a lighter greyish-brown under surface. Bolivia.

Th. phegeus Hew. (147 f, g). The figure is entirely unable to give an idea of the splendour of the colouring; the forewings are above brilliantly sky-blue with a milky-white prominent sexual-spot. Beneath marked as *lisus*, but of a dark-green ground-colour, at the proximal margin of the forewing blue. Bahia, Amazon.

Th. laudonia Hew. (148 a) forms the transition to the following species which it almost entirely resembles beneath, except the dark-green ground-colour as in *phegeus*. Above the wings are of a deep peacock-blue with a small, equally coloured scent-spot being visible only at an exposure to an oblique light. Amazon, Colombia.

Th. hemon Cr. (= *acmon* Cr.) (147 g) is larger than the preceding, above equally coloured, but with a very much larger scent-spot; beneath blackish-brown with a blue proximal half of the forewing. The ♀ is above dull brown, also beneath, here like the ♂ with metallic-green transverse lines and a white, black-pupilled eye-spot in the middle of the costal margin. The species flies the most frequently in Brazil in the Amazon district, in Guiana and Colombia, more rarely in Central America from Guatemala to Panama.

Th. arogeus Cr. is a species that has apparently not been identified hitherto, but presumably belonging here. Above like the preceding, beneath green, the darkest at the base of the hindwings, towards the margin light-blue with black transverse lines, the innermost of which in the centre forms 2 very large bows like the number 3. Described from Surinam.

12. Deniva-Group.

Th. deniva Hew. (147 c, d) approximates the preceding group by the split anal part of the hindwing; the marking beneath likewise shows a resemblance in the scheme; the apex of the forewing is clipped. Above the ♂ is metallic-blue, the ♀ dull violettish-blue, beneath brown. Brazil.

zava. **Th. zava** Hew. (153 b) which I know only from the author's description and figure, is ranged here. Above blue with broad dark-brown margins and a dark-brown discal spot. Beneath brown, darker undulated with 3 transverse bands and whitish-watered spots of the costal margin of the forewing before the centre and at the apex. No habitat mentioned.

13. Anna-Group.

anna. **Th. anna** Drc. (147 d) is an entirely isolated animal. Above metallic-blue, with broad blackish-brown margins. Beneath the forewings are brownish-grey, towards the margin strewn with whitish, in the disc opalescent blue; the hindwings are brown, densely strewn with whitish and darker scales and marked with black spots the arrangement of which approximates the most the *marsyas*-group; they exhibit 2 rather long and broad tails. Described according to 1 example from Colombia.

14. Mavors-Group.

- mavors*. **Th. mavors** Hbn. (148 b as *triquetra*). The ♂ is above bluish-green with a large brown scent-spot, also beneath green with fine black transverse lines, at the anal angle of the hindwing no distinct W. The ♀ is above and beneath plainly coloured in brown. The hindwings bear 2 tails. From Mexico through the whole of Central America to Colombia, Guiana and the Amazon; everywhere very common, but apparently not going up higher than 3 to 4000 ft.
- triquetra*. **Th. triquetra** Hew. (152 b) differs by having only one tail and a somewhat duller bluish-green colour above; beneath also in the ♂ the ground-colour is discoloured brown, only sparsely sprinkled with silvery-green scales, and the lines run somewhat differently. Panama, Surinam, Brazil.
- ella*. **Th. ella** Stgr. i. l. (148 b, as *mavors*) is easily discernible from the two preceding by the absence of the scent-spot, the under surface being quite brown also in the ♂ and the distinct W at the anal angle of the hindwing. The hindwing bears 2 tails. Colombia, Ecuador.
- paupera*. **Th. paupera** Fldr. (148 b) from Bogotá seems hitherto to be extremely rare. It resembles *ella* above, but it is of a more lustrous dark-green, beneath brown, marked like *triquetra*, without a distinct W. — **harietta** Weeks from Bolivia is probably only a variety of colours, above lustrous blue, towards the base warming into greenish.

15. Polybe-Group (*Atlides* Hbn.).

- inachus*. **Th. inachus** Cr. (= *baeton* Sepp) (148 f). A well-known species, above in the ♂ metallic indigo-blue with a moderately broad blackish-brown margin; the large, long, greyish-brown scent-spot is parted in two by the transverse vein. Hindwing at the anal angle with whitish-grey hair and variegated with silvery-green scales. The ♀ is in the basal half dull greenish bluish-grey, distally blackish-brown. Beneath brown, in the basal half of the forewing and the inner-marginal half of the hindwing green, in the basal area of the hindwing carmine with a large black eye-spot being narrowly bordered by silvery-green; abdomen beneath orange-yellow.
- carpophora*. From Panama to East Peru, Guiana and the Amazon. — **carpophora** Hew. (148 f) is the northern form and but little different; beneath, on the whole, darker brownish-black with less green and red, the black eye-spot mostly smaller and, instead, more broadly bordered with silvery-green. Mexico and Guatemala.
- carpasia*. **Th. carpasia** Hew. (148 d) is above similar, but with decidedly black veins; the proximal brown part of the scent-spot is twice as long as the distal black part. Beneath the brown wings are black-veined, without any transverse lines, only before the anal angle of the hindwing several silvery-green macular bands; in the red basal part there are 3 black spots with silvery-green pupils. Abdomen beneath orange-red. Mexico, Guatemala.
- polybe*. **Th. polybe** L. (= *atys* ♀ Cr., *scamander* Hbn.) (148 c). ♂ above turquoise-green, ♀ duller, more bluish-grey, with black veins running radiatingly into the broad blackish-brown border. Scent-spot double, the proximal half mostly lighter brown than the distal black half, the transverse vein separating both is likewise covered with modified scales of a greyish-blue colour. The under surface is olive in the ♂, in the ♀ more yellowish-brown, with black veins, the disc of the forewing in the ♂ opalescent blue. From Mexico to South Brazil and Argentina, but everywhere rare.
- halesus*. **Th. halesus** Cr. (= *dolichos* Hbn.) (148 c) is above metallic greenish-blue with a moderately broad black distal margin and a very broad black anterior angle of the hindwing. Scent-spot triple: between the smaller proximal brown part and the irregular larger distal part there is, on the transverse vein, a brown oval surrounded by single blue scales. Beneath brown; below the median of the forewing and along the proximal margin of the hindwing opalescent-blue stripes; at the base of the forewing 1, at the base of the hindwing 2 red spots, at the anal angle some golden and silvery-blue spots. Abdomen beneath orange. Widely distributed from the Southern States (Florida-California) to Mexico and Costa Rica. — Northern specimens, **juanita** Scudder, exhibit chestnut-red spots between the anal-angle-spots.

Th. gaumeri *Godm. & Salv.* (148 d) is smaller, with only 1 greyish-brown scent-spot, black veins *gaumeri*, and, at the apex of the forewing, white fringes. Beneath the blue of the forewing is much more extensive and fills up the whole cell; the anal-angle-spots at the hindwing are much broader and quite green. The ♀ is unicolorously greyish-brownish. Only from Mexico.

Th. cynara *Godm. & Salv.* (148 c). Likewise resembling *halesus*, but beneath without the discal blue, *cynara*, and the anal-angle-spots form a coherent, broad red-golden band. The margin of the forewings above much broader black. Mexico.

Th. atys *Cr.* (148 e). Larger than *halesus*, above more green, ♂-scent-spot something like that of *atys*, *polybe*, but the bordering of the proximal half, inclusive of the transverse vein, is leaden-grey. The ♀ is more silvery-green, the margins much broader dull blackish-brown. Under surface brownish, with broad darker veins and a dark band at the cell-end; at the base of the hindwing there are red spots, behind them silvery-green ones, 2 green macular rows in the black anal angle. Abdomen beneath orange-red. From Panama to Colombia.

Th. melidor *Drc.* (148 d, e) is above bluer than the preceding; beneath the dark cell-end-band is *melidor*, absent, along the costa of the hindwing and of the proximal margin there are long red stripes. Abdomen beneath vermilion. Captured in Peru in August.

Th. cosa *Hew.* (148 e). Smaller than *atys*, above deep metallic blue with somewhat broader blackish- *cosa*, brown margins; beneath lighter brown, the basal half of the forewing darker with a dark, distally light-bordered transverse band behind the cell, projecting far outwards below the lower radial vein; in front of the margin on both wings dark transverse lines, a similar one at the cell-end of the hindwing. Brazil.

Th. baxis *Godm. & Salv.* (148 d). Above likewise similar to *atys*, but of a more magnificent peacock- *baxis*, blue; the scent-spot triple as in *halesus*, the middle part more yellowish-brown. Beneath similar to *melidor*, but of a blacker fundamental tone; behind the cell of the forewing there is a series of green, small metallic spots, interrupted on the lower radial vein; the red stripes of the hindwings are of a magnificent carmine colour, between them there are opalescent silvery-green stripes. Panama. — STAUDINGER described as *vulnerata* specimens *vulnerata*, that are of a purer blue above, without a green reflection, with a narrower black margin; they are presumably scarcely to be separated.

Th. torfrida *Hew.* (148 e) differs from all the preceding species by the absence of a scent-spot on *torfrida*, the forewings, but instead there is a hair-tuft near the proximal margin of the hindwing beneath. Above dull indigo-blue with a very broad, blackish-brown apex. In the black anal part of the hindwing there are 3 silvery-green spots. Beneath almost like *atys*, but the light costal-marginal part of the forewing exhibits behind the cell a dark-brown triangular spot; of the same colour is the apex and the space between the lower median vein and the lower radial vein. Amazon.

Th. coccineifrons *Godm. & Salv.* (148 e) is very much alike, but immediately separable by the glaring *coccineifrons*, carmine forehead in both sexes and the almost black under surface of the hindwings, from which the metallic silvery-blue anal spots shine forth. From Mexico to Colombia.

Th. carthaea *Hew.* (148 g) approximates *halesus*, but it has no scent-spot; above magnificently deep *carthaea*, peacock-blue with an extremely narrow black margin, only the apex of the forewing somewhat broader black; in the black anal part of the hindwings are small, lustrous, metallic green spots. The under surface is almost black, at the bases of the wings are carmine and green spots, at the costal margin of the forewing behind the middle 3 green spots, in the anal part of the hindwing 2 short macular rows, the distal one green, the proximal one more golden. Apparently found hitherto only in Mexico.

Th. caranus *Cr.* (= *ceranus* *Godt.*, *pelops* *Cr.*, *petus* *F.*, *getus* *Ww.*) (148 g) is larger, otherwise above *caranus*, like the preceding, perhaps of a somewhat purer ultramarine blue. Beneath the bases of the wings are much more extensively deep carmine with numerous black, bluish-white-pupilled spots; the inner-marginal half of the forewing is in the ♂ violettish-blue, the ground-colour of the hindwings of a slight green lustre. From Panama, Colombia, Guiana and the Amazon.

Th. silumena *Hew.* (148 g) has a rounder shape of the wings, above lighter greenish-blue, very *silumena*, brilliant, with a broader black apex and costal margin of the wings; beneath the ground-colour is lighter, reddish-brown, the marking almost the same as in *caranus*. The forehead is red, in *caranus* almost black with silvery-blue margins round the eyes. Colombia.

Th. didymaon *Cr.* (148 g) is much smaller than the preceding with a considerably broader black apex *didymaon*, of the forewing, above deep ultramarine-blue; beneath dark brown with 3 very conspicuous white spots of the costal margin; the basal red is reduced. Brazil (Amazon, Sao Paulo).

Th. neora *Godm. & Salv.* (148 h) is still smaller, the blue more intense, still more reduced by the *neora*, extensive black, beneath the colouring and marking is just the same, but the small white spots are smaller and narrower; forehead and the hairs on the thorax are rusty-red, in *didymaon* black. Mexico, Guatemala, Colombia.

16. Phaleros-Group.

phaleros. **Th. phaleros** L. (= *silenus* Cr., *agis* Drury, *silenissa* Hbst., *chiton* F. (?) (150 a, b). Above extremely lustrous ultramarine-blue. The proximal half of the double scent-spot is round, jet-black, with grey rings, the distal half almost four-cornered, brownish-grey. The ♀ is above dull greyish-blue, with broad blackish-brown margins and the under surface-marking shining through. Beneath the ♂ is reddish-white, the ♀ more yellowish-white with 3 black transverse bands converging towards the proximal margin; distal margin with an orange tinge. Very common from Mexico to South Brazil.

battus. **Th. battus** Cr. (= *bathys* F., *bathildis* Fldr.) (150 a) has exactly the same scent-spot as the preceding, but it is smaller with narrower black margins and an orange-red anal spot of the hindwing. The ♀ is above almost white, of a pale violettish-blue lustre with the marking shining through from beneath, being well reproduced in our figure. The forehead is red. — The name of **aufidena** Hew. (= *jalan* Reak.) may be perhaps applied for the specimens originating mostly from the northern habitats, with a brilliant, deep violettish-blue, the typical *battus* being lighter blue. Very widely distributed from Mexico to Colombia.

17. Viridicans-Group.

viridicans. **Th. viridicans** Fldr. (149 f) is above lustrous green with very broad black margins, beneath almost exactly marked and coloured as *barajo* (149 e), only the white line close before the border is absent. Colombia.

barajo. **Th. barajo** Reak. (= *desdemona* Hew.) (149 e) is above lustrous sky-blue and very much distinguished by the polished spot in the costal half of the hindwing above; the ♀ is duller and more greenish-blue with the marking shining through from beneath. The under surface is brown, each wing traversed by 4 white transverse lines converging towards the proximal angle; fringes white. From Mexico to Panama, everywhere very common.

laothoë. **Th. laothoë** Godm. & Salv. (149 g) greatly resembles the preceding, though it has broader dark distal margins and dark fringes, as well as a somewhat more greenish tinge of the upper surface, the polished spot of the hindwings being absent besides. Beneath there is little difference, at the anal angle of the hindwing more black at most. The scales of the forehead are turned upwards, in *barajo* downwards. Costa Rica, Guatemala.

oceia. **Th. oceia** Godm. & Salv. (149 g) resembles *laothoë* so much that the authors themselves thought a specific separation to be doubtful. It is above greener, the margins much narrower, the fringes white; beneath the white bands of the hindwings are narrower. Costa Rica and Panama.

theia. **Th. theia** Hew. (= *aethesa* Hew. *pro p.*) (150 c, d) we join here, though it deviates greatly. ♂ above lustrous green; ♀ somewhat bluer and duller with broad black margins. Under surface grey with black transverse lines being similarly arranged as in the preceding. In front of the border of the hindwing 3 orange-yellow spots. Apparently very rare, but it has been found from Panama to Bolivia.

erybathis. **Th. erybathis** Hew. (150 a) presumably also belongs to this group. Above almost like *barajo* (149 e), but without the polished spot and with broader margins of the wings; the tails are much broader, the whole animal very delicate, in the ♀ the marking beneath shines through above, the under surface being exactly like that of *battus* (150 a) except the anal lobe being white, not orange. Not rare in Mexico, nor in Honduras.

18. Gibberosa-Group.

gibberosa. **Th. gibberosa** Hew. (149 g ♂, not ♀). Very conspicuous by the hunch-shaped projection of the costal margin of the forewing in the ♂, which is absent in the ♀. The wings are white, with a lustrous bluish-green tinge in the basal half of the forewing and the basal half of the costa of the hindwing, the marking beneath shines through above. The ♀ is entirely white with broad black margins. Colombia, Bolivia. — f. **tomlinsoni** Drc. (149 f, g, ♂, not ♀) has been described from Peru, the whole wing being above covered by an opalescent bluish-green.

phydela. **Th. phydela** Hew. (149 f). ♂ above sky-blue, the hindwings distally white, the margins of the forewing rather broadly black, the ♀ all white; in both sexes the black transverse bands beneath shine through above. — *dealbata.* In **dealbata** *form. nov.* (149 g) the whole hindwing is blue. Both the forms fly in Brazil.

numen. **Th. numen** Drc. (149 e, f) is, according to the description; a good species, since the lower median vein of the forewing beneath is vesicularly inflated in its proximal half, like in *gibberosa*, which is not the case in *phydela* which it otherwise resembles very much. It is much larger, the forewings and the basal halves of the hindwings opalescent bluish-green, in the ♀ entirely white, also beneath nearly the same markings. Roraima (Brit. Guiana).

19. Ematheon-Group.

Th. ematheon *Cr.* (149 d, e) is an extremely rare species of which only 2 specimens have become *ematheon*. known hitherto, and most peculiarly from Surinam and Peru, so that it is certainly a very widely distributed animal. Above deep-blue, on the forewing in the disc a purple-violet reflection with a very large black discal spot; distal margin narrowly black. Beneath, the black ground exhibits white and brown irroration.

Th. busa *Godm. & Salv.* (149 d) is above somewhat similar, deep-blue, in the disc a purple reflection, *busa*. in which the large black cell-spot is situated; the margin is somewhat broader black. Beneath dark brown with silvery-grey transverse speckles being united to broad areas behind the middle. From Mexico to Costa Rica.

Th. perpenna *Godm. & Salv.* (149 e) from Panama is much smaller and of lighter colours with a *perpenna*. broad black apex of the forewing and a smaller discal spot without the spot at the cell-end.

Th. undulata *Hew.* (149 e). Above lustrous green like *viridicans* (149 f), without the scent-spot, beneath *undulata*. marked almost just like *busa*, but lighter brown. The ♀ is above a little duller and bluer with broader blackish-brown margins. Lying before me from Colombia and Brazil (Itaituba).

20. Tolmides-Group.

Th. tolmidēs *Fldr.* (149 a) is allied to the preceding group and forms the transition to the *aegides-* *tolmidēs*. group. Above lustrous blue with moderately broad black distal margins. In the black anal part of the hindwing we notice the beginnings of a blue marginal line. Beneath greyish-brown with very similar linear markings like those of the following group, in the basal part darker. The nomenclatural type occurs more to the south than the form *hyas* *Godm. & Salv.* (149 b) from Mexico, Guatemala, Costa Rica and Panama. The ♂ of it has *hyas*. above much narrower black margins and is beneath more chestnut-brown, the linear markings are less distinctly prominent.

Th. danaus *Fldr.* (149 b) likewise closely approaches to this type, though it might also better form *danaus*. a group for itself. Above more greenish-blue. Beneath blackish-grey with bluish-white linear markings: on the forewings only one oblique, bent line behind the cell, the margin somewhat darker; the proximal line of the hindwing is removed inwards in the broad subcostal area, the distal one gets jaggy towards the anal part, the space between it and the somewhat darkened margin is slightly dusted in whitish. The anal lobe is split off like in the *lisus*-group. Colombia, Bolivia, Peru.

Th. tityrus *Fldr.* (149 b) is above radiantly greenish-blue, the broad black margin sharply defined, *tityrus*. Beneath brown; on the forewing 2 white postdiscal lines, disappearing in the whitish proximal margin, the proximal one forms proximally an acute angle in the submedian area, the distal one is a little broader. Hindwing before and in the centre with 2 white lines, the latter forms at the proximal angle a distinct W, then the costal margin up to the lower median vein is followed by a coherent band of a magnificent deep carmine colour, on both sides bordered by white, next to it between the median veins a black spot; in front of the border yet a fine white line. Lying before me from Colombia, from the Rio Negro.

Th. appula *Hew.* (149 c) which we include here is apparently very rare; it is compared with *danaus appula*. by HEWITSON, but it differs greatly from all those known, exhibiting also resemblances to *phoenissa* (152 e) or *havila* (148 b). Before me is also a ♀ which is above duller blue than the ♂ which exhibits a small black scent-spot in the upper cell-corner, with broader black margins. Beneath light brown, the space between the two proximal white lines somewhat darkened, behind it extensively dusted in whitish. Colombia, Venezuela and Bolivia.

21. Aegides-Group.

Th. aegides *Fldr.* (148 h) is above blue with rather broad black margins without a sexual spot; *aegides*. in front of the border of the hindwing is, particularly distinct in an anal direction, a bluish-white line; fringes orange-brown; the ♀ is of somewhat duller colours. The under surface is cinnamon-red with 3 fine bluish-white transverse lines proceeding on the forewing from somewhat thicker and more purely white costal spots; on the hindwing, close before the border, there is a fourth, similar line; anal lobe black interspersed with cinnamon-brown scales; above it the proximal margin is somewhat sinuous and here there is a thicker white spot. Venezuela, Colombia. — form. **amplitudo** *Drc.* (149 b) has only half as broad black margins and a violet tinge in *amplitudo*. the blue; it is the form flying in Ecuador. — On the contrary, the form flying more to the north in Central America (Mexico and Guatemala), **furina** *Godm. & Salv.* (148 h), has much broader distal margins and a darker, *furina*. more blackish-brown under surface.

Th. cyda *Godm. & Salv.* (148 h) resembles *barba* (149 a) above by the very broad black distal *cyda*. margins and the lustrous blue colour; beneath it scarcely differs from *aegides*; both sexes are equally coloured. Costa Rica.

- epopea*. **Th. dignota** *sp. nov.* (153 b) differs from *aegides* (148 h) by a rather large, round, greyish-brown scent-spot at the cell-end, a very sharp apex of the forewing, below which the distal margin looks almost concave, red-brown fringes and tail; the anal lobe is likewise quite red-brown, in its centre pupilled with some greenish-silvery scales, the fringes at it partly white; the bluish-white line in front of the border is absent altogether. Beneath, on the cinnamon-brown ground-colour, are the same transverse lines, but they are fine black, strewn with silvery-grey scales and only towards the costa of the forewings somewhat broader and whiter; the third, counting from the base, is regular and sharply dentate with distally concave bows. Described according to a ♂ from Bogotá (Coll. FASSL).
- comae*. **Th. comae** *Drc.* (149 a) forms the transition to the following species by the ♂ forewing exhibiting a large discal spot of modified scales of an oval shape, which, however, stands out against the colour of the wings only in an oblique exposure to light; besides this the species resembles above *aegides* (148 h); the under surface is more blackish-brownish, the line-marking otherwise very similar, but on the forewings, subapically, are the beginnings of a 4th line and on the hindwings, between the median veins and in front of the black-pupilled anal lobe, are 2 black spots in light, reddish surroundings. Colombia (Muzo; Rio Aguaca Valley).
- ion*. **Th. ion** *Drc.* (149 a) has the same, hardly noticeable scent-spot, is somewhat lighter, more greenish-blue and has much narrower, black distal margins. Beneath like the preceding, but the ♂ has an opalescent blue discal spot of the forewing. Colombia. — From Medina (East Colombia) there is a ♂ before me (from the Coll. FASSL) which I should like to include here provisionally as a subform: **extrema** *form. nov.* (153 b). It is above still lighter, greenish silvery-blue, entirely without a black distal margin, the discal spot is above still larger and beneath the whole forewing is opalescent blue, so that there remain of the transverse lines only 3 minute white spots at the costal margin.
- barba*. **Th. barba** *Drc.* (149 a) has narrower wings than the other representatives of the group, above very broad black margins and beneath on the forewings only one bluish-white transverse line crossing the disc; on the hindwings the basal transverse line is only indicated by a costal marginal streak, the marginal line is absent altogether. Colombia (Muzo; Rio Aguaca Valley).
- auda*. **Th. auda** *Hew.* (149 b, c) is a somewhat smaller species, above more violettish-blue with broad black margins; beneath greyish-brown with quite a similar linear marking as the preceding species, but in front of the border of the hindwing are 2 undulate, parallel, light lines, between them, at the anal angle, 3 black, triangular spots being above bordered by orange-red. Occurring in Colombia and common, but it also lies before me from Lino (Panama) from the Coll. FASSL.
- chlamydem*. **Th. chlamydem** *Drc.* (149 c, d) is perhaps only a form of *auda*; above more indigo-blue with broader black margins; beneath, on both wings, the distal white transverse lines are more distinct, and on the hindwings the discal markings are doubled by proximally white dusting. Peru, at an altitude of 5 to 6000 ft.
- sala*. **Th. sala** *Hew.* (159 a). We herewith include some species exhibiting at the same time close relations with the *coelicolor*-group following later on. *Sala* is above dull violettish-blue, on the forewings with broad blackish-brown margins, on the hindwings very narrowly margined with the fringes parted by white towards the anal angle. Beneath dark brown, in the ♂-disc of the forewing with a slight steel-blue shine. The marking is similar to that of *auda* (149 b, c), but on both wings the basal transverse lines are absent, and the post-discal of the hindwing runs almost straight from the costal margin to the lower median vein. Colombia.
- maraches*. **Th. maraches** *Drc.* (159 a) is very similar, above more lustrous steel-blue, the shape of the wings as in *epopea* (157 c) and the tails as fine as they are there. Beneath not so red-brown, more blackish-brown, the lines clear and distinctly light-blue, much straighter, on the forewings at the costal margin more moved apart, continued to the proximal margin, the submarginal on the lowest subcostal vein distally obtuse-angled. On the hindwings the postdiscal begins also much further towards the base, at the anal angle there are only 2 deep brown-red spots. Colombia (Cañon del Tolima, FASSL).
- salaeides*. **Th. salaeides** *sp. nov.* (159 a) is very closely allied to *sala*, but it is above of a lustrous ultramarine-blue, the margins and apex only half as broad and jet-black, the shape like *sala*, but the tails very fine. Beneath almost just the same as *sala*, but on the forewings the postdiscal makes a deep bend towards the base, below the lower median vein; on the hindwings it begins at the costal margin more towards the base, and there is a second, dusty-white lunular line in front of the border; 3 red anal lunae. Colombia: Pacho (FASSL).
- peonida*. **Th. peonida** *sp. nov.* (159 a) likewise greatly approximates the preceding species, above brilliantly metallic sky-blue, with a broad black apex and distal margin of the forewing, a similar costal margin of the hindwing, and a narrow distal margin; in the anal lobe a short white line; the base of the fringes in that lobe also white. Beneath very much like *salaeides*, distinguished by a short metallic-blue stripe in the disc of the

hindwing near the base; only one red eye-spot between the tails, between it and the black anal spot white dusting. Colombia: Rio Aguaca Valley (FASSL).

Th. aurorina *sp. nov.* (159 a) is undoubtedly the most magnificent species of this group, above almost *aurorina*. like *aurora*, radiantly light-blue with a large blackish-brown scent-spot filling up nearly the whole cell, and a moderately broad black apex, the margins otherwise very narrow black. Beneath blackish-brown, at the proximal margin of the forewing somewhat lighter, marked like *coelicolor* (157 b), but the lines beautifully light-blue, on the forewings bent uniformly; on the hindwings, in front of the border, indistinct darker spots in the spaces between; only one red spot of the tail. Colombia: Cañon del Tolima; Quindiu Pass (FASSL).

Th. thargelia *Burm.* (159 a) is closely allied to this group, though greatly deviating. Above plainly *thargelia*. greyish-brown, the ♂ with a blue disc, on the hindwing the black marginal line is proximally whitish bordered towards the anal. Beneath just as dark greyish-brown with whitish postdiscals being proximally finely bordered by black, on the hindwings running straight from before the middle of the costal margin to the lower median vein close in front of the border, in order to form towards the inner-margin a very high, pointed W; the sub-marginals are far off from the border, broader black, proximally white. analwards there are behind it 2 large orange, black-pupilled spots. The marginal line distinct, proximally on the hindwings very fine white. Fringes whitish. Abdomen beneath ochreous-yellow. Argentina.

Th. cadmus *Fldr.* (149 c) has, like the following, a much rounder shape of the wings, above in the *cadmus*. basal half of a radiant greenish-blue, outside blackish-brown, before the anal angle with the beginnings of a blue marginal line. The ♀ is a little duller, more silvery. The under surface is red-yellow, again with the same light-blue linear markings which, however, are here much more dentate, particularly on the hindwings. Common in Panama, Colombia, Bolivia, Venezuela, Guiana.

Th. timaeus *Fldr.* (149 c) is above bluer, the apex of the forewing somewhat more pointed, the tails *timaeus*. shorter. Beneath, the forewings have only one bluish-white transverse line, and at the apex there are 1 or 2 white dots, the lines on the hindwing are not so dentate, running more uniformly. Colombia, Bolivia.

Th. petelina *Hew.* (149 d) not lying before me is placed here. Above very much like the two preceding *petelina*. ones. Beneath red-brown, on both wings a white discal streak, behind it 3 white transverse lines; on the hindwing, besides, a moon-shaped spot near the base, in the centre a light-blue macular band and behind it a broad red-brown, white-bordered band; the spot of the tail and the anal spot brown, proximally bordered by light-yellow. From Costa Rica and Panama.

22. Havila-Group.

Th. adamsi *Drc.* (148 h) is difficult to place; as it is compared with *havila* by the author, it may *adamsi*. be placed here, although it has no scent-spot and has 2 tails, for which reason it would have perhaps been better placed to the *aegides*- or *danaus*-group (p. 753). Above lustrous greenish-blue, towards the margin more purple; distal margin narrow black. Beneath chocolate-brown with bluish-white lines. Peru.

Th. havila *Hew.* (148 b) is not well recognizable from HEWITSON's figure being copied here. The *havila*. ♂ is above deep ultramarine-blue, towards the margin of a purple lustre. Scent-spot oblong, double, the part in the cell browner than the blackish part behind it; anterior angle of the hindwing particularly broad black. The under surface is greyish-brown with 3, towards the anal angle somewhat convergent lines of a blue scaled striation, those towards the margin broader and more faded; between the median veins of the hindwing a small red-yellow, black-margined eye-spot. Abdomen beneath orange-yellow. Colombia.

Th. margaritacea *sp. nov.* (153 b). Upper surface light greenish-blue, with a mother-of-pearl gloss, *margaritacea*. entirely without the black margin, only the fringes blackish grey. The brown scent-spot small, procumbent-oval, pointed at both ends, behind the cell. Hindwings remarkably long-stretched; in the specimen before me there is only one tail, but there seems to have been a short small tail also at the upper median vein. Under surface of the forewings opalescent greenish-blue with a narrow, blackish-grey costal margin and apex, the place of the scent-spot prominent as a small hunch; hindwings blackish-grey, sparsely strewn with green, in the cell and towards the proximal margin covered with long hair. A little before the middle of the costal margin, in the subcostal space, a bluish-green streak-spot; in front of the border 3 rather closely adjacent, bluish-green silvery lines, indistinct, consisting only of scattered, single scales. Anal lobe as in *danaus* (149 b), to which it may also be allied, somewhat split. 1 ♂ from Muzo, Colombia. (Coll. FASSL.)

Th. celelata *Hew.* (149 c) is likewise a species difficult to place. Above something like *cadmus* (149 c), *celelata*. beneath brown, marked like *havila* (148 b), but on each of the wings one whitish line nearer to the base; the costal margin of the forewing is strewn with white, all the white lines broad, somewhat faded and strewn with brown. Described from Brazil.

23. *Platyptera*-Group (*Micandra Schatz*).

platyptera. **Th. platyptera** *Fldr.* (153 c) according to our present conception, is not to be separated from *Thecla*, regarding the genus. In the scheme of markings beneath it offers close resemblances to *cadmus* (149 c) and may, therefore, be placed here. Above like *ion* (149 a), also with a similar large scent-spot reaching further towards the base only in the cell. Beneath the forewing is of a brilliant blue, the proximal margin whitish-grey, the costal margin and distal margin narrowly black. Hindwings without tails, black with 4 very fine dentate lines consisting of single, scattered bluish-white scales; in front of the border are somewhat larger double-spots. Colombia, Venezuela, Peru.

circinata. **Th. circinata** *Hew.* (149 d) we also place here, as it is beneath marked exactly like *timaeus* (149 c), although it looks above quite differently: deep ultramarine-blue, with a black margin occupying almost half the forewing, the untaild hindwings are only at the costal-marginal angle somewhat broader black, the distal margin being narrow. Costal margin whitish-grey, below it a large, dark blue scent-spot strewn with black. Beneath the ground-colour is blackish-grey, the lines light-blue; the forewing exhibits an opalescent blue discal spot. Colombia, Bolivia. The species at the same time shows close relations with the following group.

sapho. **Th. sapho** *Stgr.* (146 c) has been placed to *Micandra* by the author without the reasons being mentioned, but it seems much rather to be a *Theorema*. It was described from Colombia and has hitherto apparently not been found any more.

24. *Eronos*-Group.

eronos. **Th. eronos** *Drc.* (153 c) is above magnificently peacock-blue with a darker apical third of the forewing, without a scent-spot and tails; the lower median vein of the hindwing is set with long hair. Beneath, the forewing is in the disc of an extensive opalescent blue, the hindwing almost black, strewn with scales of a greenish reflection, and with 2 similar, undulated, quite indistinct transverse lines. Colombia.

trochus. **Th. trochus** *Drc.* (153 c) is very similar, but above brilliantly green and beneath on the hindwings lighter with more distinct light transverse lines and a red, black-pupilled spot between the median veins. On the forewings the opalescent-blue colour is confined to the part round the median veins behind the cell. Colombia (Pacho, Muzo, Rio Aguaca Valley).

25. *Thara*-Group.

thara. **Th. thara** *Hew.* (= *ivelia* *Gosse*) (153 c). The ♂ is above magnificently light ultramarine-blue, the ♀ somewhat more greenish with a broad black apex of the forewing. Beneath brownish-grey with 2 rows of white, proximally darker-bordered lunular spots behind the middle, both wings with a white discal streak, the hindwings towards the base below the costal margin with an additional white streak-spot; the proximal white line forms a pointed W at the proximal margin of the hindwing, the surroundings of the distal line are here more or less strewn with bluish; anal spot black, above bordered by white, between the tails a black spot bordered above by orange. Brazil (Rio, Sta. Catharina).

eunus. **Th. eunus** *G. & S.* (153 d) is coloured and marked just the same on both surfaces and has also beneath the same black scent-spot at the base of the forewing below the median, but the costal margin of the hindwing is bent more convex and on the upper surface is a lustrously polished scent-spot like in *barajo* (149 e) below the costal margin at the base of the hindwing. From Guatemala to Colombia (Muzo).

26. *Gigantea*-Group.

gigantea. **Th. gigantea** *Hew.* (153 d). I know only from HEWITSON's description and figure. Above light-blue with brownish-black veins and margins and a very large discal spot. Beneath reddish-brown with cell-spots and dentate lines which are bordered by white on the forewings only distally, on the hindwings on both sides; in front of the border is yet a brownish, proximally white-bordered macular band, and at the anal angle 2 black spots being bordered above by red-yellow. Pará.

27. *Linus*-Group (*Arawacus Kaye*).

linus. **Th. linus** *F.* (= *lincus* *Godt.*, *aetolus* *Cr.*, *amelia* *Hbst.*) (150 c) is above white with the marking showing through from beneath, a broad blackish-brown distal margin and 2 similar lines in front of the border of the hindwing. The ♂ exhibits, below and behind the cell, a large, roundish scent-spot which mostly sends forth yet a tiny spot into the lower cell-corner and which, in contrast with the following species, always ends roundish outside on the lower median vein. Beneath there are 5 black stripes being convergent towards the proximal angle on the hindwing; the proximal and distal margins are orange, the latter colour bordered by the fifth black stripe running near and parallel to the distal margin, the two next ones approximating each other. Anal angle black with 4 white dots. Colombia, Venezuela, Amazon, Bolivia.

Th. togarna Hew. (150 b, c) is very similar, mostly somewhat smaller; the very variable scent-spot *togarna*, is more triangular, on the veins, interrupting it by their light colour, it is distally produced taperingly, particularly on the lower median vein. Beneath, on the hindwings, there are only 4 black stripes not parallel to the distal margin, the orange border not defined by black, the two next stripes do not approximate each other more than the others; the anal angle is mostly much lighter in typical specimens. — **lincoides** form. nov. (150 c). I deno- *lincoides*, minate a larger, robust form resembling *linus* still more by its broader black beneath, and also above the discal spot it is larger and is almost or entirely confluent with the marginal band. This latter form flies more in Colombia and Ecuador, the type being widely distributed from Mexico to Bolivia.

Th. aethesa Hew. (150 c) is an extremely rare species from Bahia resembling *linus* almost entirely *aethesa*, in the marking beneath, but the ground of the wings above and beneath is reddish-brown instead of white.

Th. leucogyna Fldr. (150 b) resembles in the ♀ above the *linus*- and *togarna*-♀♀, but it has an orange- *leucogyna*, yellow anal spot of the hindwings; the ♂ is above dark violettish-blue. Under surface creamy-white with fine black lines, an orange anal-angle spot of the hindwings and in the ♂ with a large black scent-spot below the cell of the forewing. Colombia.

Th. phaea G. & S. (= *sito* Btlr. & Drc. nec Bsd.) (150 b) is most similar to the preceding, the *phaea*, ♂ more bluish-grey, paler, the costal margin of the hindwing, and mostly a spot between the blue and the apex of the forewing, are whitish, the ♀ usually has a broader blackish-brown distal margin and on the hindwing mostly 2 distinct dark lines in front of the border (*leucogyna* is marked either without these lines at all or only with the beginnings of them at the anal angle). Beneath in the ♂ the black scent-spot has a narrower and brown border, in the form **phaenna** Godm. & Salv. quite chestnut-red. Central America (Honduras to Panama). *phaenna*.

Th. sito Bsd. (149 h) is above bluish-grey also in the ♀, the ♂ lustrous violettish-blue, easily discernible *sito*, from the preceding by the polished scent-spot on the hindwing above near the costal margin, the one on the forewing beneath being bordered by orange-yellow approaching red-brown. Mexico to Nicaragua.

Th. melibaeus F. (= *euryides* Hbn.) (150 d) resembles the preceding above, but without the large *melibaeus*, orange-red anal spot; beneath the ground-colour is yellowish, the lines are finer and towards the costal margin they are traversed by the fine, black veins. Brazil.

Th. azaria Hew. (149 h) presumably belongs to the same group as the following, though it is above *azaria*, blackish-brown with a white, rounded median band and only little blue towards the base and in the disc of the hindwing. Beneath the black bands are much broader, more than in *battus* (150 a), entirely flown together at the base of the forewing. Patria unknown.

Th. pedusa Hew. (149 h) is above blackish-brown with a small round discal spot, the disc of the *pedusa*, hindwing blue, at the anal angle an orange spot. The under surface is blackish brown with narrow silvery-white stripes. The ♀ is above lighter and more reddish brownish-grey. Amazon.

28. Umbratus-Group.

Th. umbratus Hbn. According to HÜBNER's figure, the butterfly has about the shape of *luothoë* *umbratus*, (149 g), but it is smaller, only about half as large as *perpenna* (149 e). The wings are of a bright lustrous cyanide-blue above, the forewings with a broad, the hindwings with a narrower black margin; the scent-spot of the ♂ whitish. The under surface is dirty leaden-grey; the forewing with 2 parallel, the hindwing with 3 analwards convergent transverse stripes; before the apex of the hindwing a rusty-red, oval spot. Is stated to originate from Yucatan.

Th. parthenia Hew. (150 h) exhibits in its whole shape and scheme of markings also relations to *parthenia*, the *loxurina*-group. Above lustrous blue with an oval scent-spot and a broad black apical part of both wings. The under surface is sooty grey, on the forewing with a dark-brown, faded band behind the centre and another one in front of the border. Hindwings speckled in black, in the basal part with several dark indefinite spots, a median band being pointedly broken towards the anal angle and in front of the border a series of small brownish spots. From Mexico to Nicaragua.

Th. catadupa Hew. (153 e) is unknown to me in nature, but seems to approximate the two preceding *catadupa*, ones. Above lustrous blue with broad black margins, without a scent-spot; hindwing with a broad tail and a large anal lobe. Beneath greyish-brown, on the hindwings darker. Forewing with a broad brown band behind the centre and a narrower band in front of the border, both bordered by white on both sides; the hindwing exhibits 3 bands being equally distant from each other. Ecuador.

Th. chaluma Schs., according to the description, seems to me the least unfit to be placed here. Above *chaluma*, the basal $\frac{2}{3}$ of the forewings and the hindwings are dull violettish-blue, distally black. Hindwing with a velvety-

black marginal line, proximally tinged whitish with a long broad tail. Beneath dull greyish-brown; forewing with a broad, distally whitish-dusted median shade, a similar one in front of the border and in front of it another one interrupted by the veins. Hindwing with a broad dark-brown median shade, the broadest in the cell, strewn with some bluish-white scales, and a narrower distal shade being dentate on the veins; in front of the border a broad, brown band being analwards dusted in grey, on the border a black line. Expanse of wings: 31 mm. Sta. Catharina.

29. *Loxurina*-Group.

- loxurina*. **Th. loxurina** *Fldr.* (150 g) is an extremely variable species. In the typical form as it flies e. g. near Bogotá, but also on the Cuesta of Cillutincara in Bolivia at an altitude of 3500 m, it is above deep violettish-blue with a rather broad black apex and distal margin and a small greyish-brown scent-spot in the upper cell-corner; the costal margin and the fringes are red-brown. The ♀ is duller, more greyish-blue with a much broader apex and distal margin; the tail and anal lobe deep red-brown, strewn with whitish scales. The under surface is dark cherry-coloured, strewn with bluish-white scales, so that particularly on the hindwings towards the anal part a violettish shade is created, with a red-brown line behind the centre, forming an acute angle on the lower median vein on the hindwing; in front of the border on both wings a series of small purple-brown spots. According to the locality, the occurrence of red creates a very different appearance: On the Quindiu Pass (3800 m) in the Colombian Central Cordilleras there appears at first a red colour towards the apex of the forewing, at the costal angle of the hindwing and at the anal angle (= **quindiensis** *form. nov.* 153 e), being extended to an almost entirely red upper surface, so that there remains only a black triangular spot in the middle of the costal margin of the forewing, by which the specimens resemble almost *atymna* (150 g): **atymnides** *form. nov.* (153 e). *quindiensis*.
atymnides. Beside the typical form there is another form in Bolivia at an altitude of 3000 m: **cillutincarae** *form. nov.* (153 e) *cillutincarae*.
cillutincarae. In which most strangely the red occurs at the anal angle of the fore- and hindwings. Finally, on the Monte Socorro (West Cordilleras) at an altitude of 3500 m, the hindwings are more or less red, the forewings remain blue: **fassli** *Drc.* (= *socorrensis* *Dgn.* i. l.) (153 e). Perhaps the two last forms are to be separated as a species of their own.
fassli.
amatista. **Th. amatista** *Dogn.* (= *candor* *Drc.*) (150 h) is very similar, smaller, with a darker, duller violet above; the anal part of the hindwing is extended to a short tail, a lobe is entirely absent. Beneath the whole basal half of the forewing is greyish-brown. Peru and Colombia.
atymna. **Th. atymna** *Hew.* (150 g) is likewise similar, but without a scent-spot, the ♂ deep violettish-blue, the ♀ is brown-orange. Beneath the forewings exhibit a dark cell-streak, both wings in front of the border another dark band. Tail and anal lobe as in *loxurina*. Ecuador, Bolivia.
catrea. **Th. catrea** *Hew.* (150 g) is presumably allied, as the shape of the hindwings corresponds with *loxurina*, but they are broader. Above radiantly blue with a broad black apex, beneath deep red-brown, strewn with white scales forming on the forewings behind the cell an indistinct short transverse line, on the hindwings in the centre a rectangularly broken dentate line, behind it yet a light shade; costal angle somewhat lighter brownish; below the costal margin, before the middle, there is yet a black, bluish-white-pupilled spot. Abdomen above blue, beneath orange-brownish. Brazil (Rio Grande do Sul).
dissentanea. **Th. dissentanea** *sp. nov.* (153 e). Shape of the wings as in *amatista*. Forewing yellowish-brownish, towards the base somewhat dusted in a light lilac-blue; hindwings light lilac-blue with a narrow brownish distal margin, fringes white; in the basal area the dark under surface gleams through. Beneath the forewings are greyish-brownish in the basal two thirds, on the lower median vein distally standing forth; marginal area white, at the proximal angle more yellowish with a narrow greyish-brown border and a similar line in front of it. Hindwing in the basal half blackish-grey, strewn with yellow and with white hair, particularly towards the proximal margin; distal area white, on the lower radial extending into the cell like a tooth; distal margin with the tail and a stripe before it being distinct only at the costal angle, are of the same colour as the basal part. Described according to 2 ♂♂ from Cuzco (Peru). (Coll. FASSL).

30. *Arria*-Group.

- arria*. **Th. arria** *Hew.* (153 f). Above dull greyish-brown, beginning from the median of the forewing greyish-blue, also in the disc of the hindwing; along the upper cell-edge of the forewing a narrow, long scent-spot. Anal angle of the hindwing somewhat advanced, without a tail. Beneath greyish-brownish, densely dusted in white; forewing at the proximal margin, beginning from the median, in the basal half shining greenish-blue, behind the middle with a yellow-brownish stripe; hindwing in front and behind the middle with just the same dentate lines and discal stripe. Colombia, Ecuador, Peru.
hybla. **Th. hybla** *Drc.* (153 e, f) is larger, above with a more brilliant and more extensive greenish-blue, without a scent-spot. On the under surface the dentate lines are purple-red and the surface of the wings is sparsely strewn with red, particularly towards the base; on the forewing, in the cell, there is a greenish-blue stripe, below it is an opalescent olive colour. Described from Ecuador.

Th. adunca *sp. nov.* (153 g) lying before me only in one ♀ is undoubtedly closely allied to *hybla*, though *adunca*. it has remarkably narrow forewings with a rectangular apex and very long-stretched hindwings with a concave costal margin and a long anal part being curved inwards. Above lustrous violettish-blue, on the forewings also above the cell, the costal margin narrow, the distal margin broad black. Costal angle of the hindwing broad blackish-brown, gradually tapering to the anal apex. Beneath the forewings are brownish-grey, with red scales at the cell-end; far behind the middle a darker undulate transverse band interspersed with red scales, extending as far as the lower median vein and being distally white-scaled like the outermost marginal area in front of which there are red crescentiform spots. Hindwings of a purer grey, strewn with red scales, with two strongly dentate red transverse lines and between them a red discal streak; the distal transverse line is distally tinged in white, running from the distal third of the costal margin in a straight direction as far as down to the submedian fold close in front of the border and then bending round acute-angled to the proximal angle, as it is the case in *loxurina*. The marginal part is, particularly towards the costal margin, lighter whitish, on the ends of the veins are thick black-red dots. Monte Tolima (Colombian Central Cordilleras at an altitude of 3200 m) in the Coll. FASSL.

Th. mirma *Hew.* (153 f) differs from *arria* by the absence of the scent-spot, above in the ♂ entirely *mirma*. brown forewings which are dusted in a greenish bluish-grey in the ♀. The under surface is browner with but one brown dentate line on the hindwings, behind it brightened up by reddish-white. Colombia. Peru.

Th. tyrrius *Drc.* (153 f, g) is to be separated from the preceding by the light-brown oblong scent-spot *tyrrius*. at the cell-end; above otherwise similar. Beneath brownish-grey strewn with dark-red scales, with the same dentate line behind the middle and an obsolete row of moonspots in front of the border; in the disc of the forewing, as in the preceding, an opalescent blue stripe. Ecuador.

Th. mishma *Hew.* (153 f) has above brilliant metallic-blue wings with broad, blackish-brown distal *mishma*. margins. The under surface greatly resembles that of *arria*, more red-brown, the dentate line of the forewing begins at the costal margin with an isolated spot. Colombia.

Th. oxida *Hew.* (153 f). Wings above deep violet, only the costal margin of the hindwing of a some- *oxida*. what purer blue with a very narrow scent-scale-stripe. along the upper cell-edge of the forewing. Fringes blackish-grey. Beneath likewise marked very much like the preceding, darker brownish-grey, strewn with red, the dentate lines more interrupted, not so coherent, in the ♂ below the cell of the forewing opalescent blue. Ecuador, Peru.

Th. schausa *Jones* (153 f). The ♂ is above black, the cell and submedian area metallic purple blue, *schausa*. behind the cell with a small scent-spot, the anal angle of the hindwing tan-coloured, fringes grey. Under surface more purple-brown, thickly strewn in red with red dentate lines, a red marginal band and a tan-coloured border; the forehead is red, too. The ♀ is of a duller blue, with a broader black border. Brazil. (Castro, Sao Paulo.)

Th. aurugo *sp. nov.* (153 g) resembles *oxida* above by the deep violet colour, but it has no scent-scales *aurugo*. along the subcostal, the distal margin is narrower black, the fringes orange-brownish. On the under surface the wings are very conspicuously lemon-coloured, strewn with red scales, and with similar, though not no very dentate transverse lines. Nearly the whole proximal margin of the forewings inclusive of the lower cell-half is of an opalescent greyish-green colour, the abdomen beneath orange-brownish; the basal half of the proximal margin of the hindwing is more greyish-brown. According to 2 ♂♂ from Cuzco (Peru) from the Coll. FASSL.

Th. commodus *Fldr.* (153 g) to a certain degree approximates *hybla* and especially *adunca*. The *commodus*. shape of the hindwings like in the latter. Above lustrous greenish-blue with very broad blackish-brown margins; beginning from the distal half of the cell the blue colour warms into a deep metallic olive-green towards the apex. Beneath the scheme of markings is likewise similar; on the hindwings the two dentate lines are separated at the costal margin by a large, olive-greenish or yellowish triangular spot; the marginal area is olive-green with small, purple-brown spots in front of the border in whitish-grey rings, being proximally mounted by angular spots of the same colour. Colombia.

Th. elongata *Hew.* (150 f) is likewise another specialisation of the same group. The blackish-brown *elongata*. forewings are only below the cell strewn with metallic blue, at the cell-end is the hardly noticeable large black scent-spot. Hindwings in the inner-marginal half somewhat more extensively blue. Beneath blackish-brown, at the proximal margin and border of the forewing lighter, almost whitish, with several, irregularly undulate, dark lines. The hindwings appear marbled by densely strewn light scales and exhibit several very irregularly dentate transverse lines. Marginal line distinctly black. From Ecuador and Bolivia.

Th. bilix *sp. nov.* (153 g) approximates *mishma*. Above lustrous metallic-blue with broad black *bilix*. margins and apex, costa and fringes red-brown; hindwing with a long-extended anal angle and equally long tail on the lower median vein. Beneath greyish-brown, strewn with red, with transverse lines consisting of incoherent lunular spots, on the forewings 2 close in front of the border, on the hindwing 3 equally distant from each other; each wing exhibits red discal transverse streaks; the inner-marginal blue is absent. Described according to a ♂ from the Rio Aguaca Valley (Colombia) from the Coll. FASSL.

31. Goleta-Group.

Th. goleta *Hew.* (154 e) is immediately recognizable by the peculiar shape of the wings with the *goleta*. deep concave indenture between the median and radial veins of the forewing, and by the long-stretched anal

angle of the hindwing. Above brown; beneath dull brown, on the forewing before the apex at the costal margin a light small spot bordered on both sides by brown. Hindwings whitish, clouded in brown; a small spot at the base of the costal margin, a broader band in the centre and an irregular marginal band dark-brown. Colombia.

crambusa. **Th. crambusa** Hew. (154 f) is somewhat larger, of the same shape of the wings, but with a short small tail on the lower median vein. Brown with small black spots in the anal part of the hindwing. Fringes white, on the forewing partly brownish. Beneath very much like the preceding, somewhat more multifariously marbled with a chestnut-brown spot bordered on both sides by whitish in the middle of the proximal margin of the hindwing, between the median veins a rusty-yellow spot and near the anal angle greyish-white dusting. Brazil, Bolivia.

binangula. **Th. binangula** Schs. is unknown to me like the following, but presumably belongs here; the shape of the wings is the same as in *crambusa*. Above dark-brown with a darker spot at the cell-end and some blue at the base of the forewing; hindwing, except the broad brown costal margin, light-blue with a small black spot between the median veins. Beneath greyish-brown with a dark cell-end spot bordered on both sides by white; the whitish apex is marbled in brownish-grey and proximally bordered by a brown, distally white shade. Hindwing with a round brown, white-ringed spot at the base of the costal margin; postdiscal double, whitish, inwardly bordered at the costal margin and proximal margin by a white angular spot; distal margin darker, dusted in reddish towards the anal region. Expanse of wings: 19 mm. Peru.

bolima. **Th. bolima** Schs. is much larger, the forewings more rounded. Above similarly coloured, but with black spots in front of the distal margin of the hindwings. Also beneath very similar with distinct brown, white-ringed spots in the centre of the costal-, cell- and proximal margin. Castro (Paraná).

32. Culminicola-Group.

culminicola. **Th. culminicola** Stgr. (153 g). Above deep violet with black margins and a particularly broad apex. Fringes white-speckled. STAUDINGER, in his description, has overlooked the greyish-brown scent-spot at the upper cell-end. Beneath blackish-grey, particularly distally strewn with white, with black dentate lines. The ♀ is above extensively light bluish-grey with a lilac shine. Colombian Andes at an altitude of 3500 to 4400 m, also from Cuzco (Peru).

alatus. **Th. alatus** Drc. (153 g, h) may be a distinct species owing to the unspeckled reddish fringes. The upper surface is lighter violettish-blue with a red lustre, the scent-spot is the same. The disc of the forewing beneath orange. Described from North Peru (11 500 ft.).

anosma. **Th. anosma** sp. nov. (153 h) is above quite dark-brown without a scent-spot, only the hindwings exhibit a faint violet lustre in the disc on being obliquely exposed to the light. Fringes unspeckled, brown, hindwing with a longer small tail at the lower median vein. The monotonously greyish-brown under surface strewn with red scales, with incoherent dark lunular spots entirely resembles that of *bilix*. A ♂ from Bogotá (3000 m) from the Coll. FASSL.

33. Irus-Group (*Incisalia* Minot).

augustus. **Th. augustus** Ky. (= *augustinus* Ww.) (153 h) undoubtedly is closely allied to the preceding group. Above brown, the hindwings analwards copper-reddish. The under surface is reddish-brown, in the basal half darker with a dark dentate median band of the hindwing and lighter, proximally darker-bordered, small triangular spots in front of the more purple-brown border. Distributed in the northern and western parts of North America. Larva carmine-red, with short hair.

iroides. **Th. iroides** Bsd. is extremely allied to *augustus*, above not different, beneath the space behind the postdiscals is not lighter than the border, the markings are more indistinct, the forewings almost unmarked. Pacific States. — f. **immaculata** Cokle is an albino form: straw-coloured to canary-yellow, above and beneath without any spots. A unique specimen from Kaslo in British Columbia.

fotis. **Th. fotis** Strecker. Size and shape of *augustus* (153 h); above unicolorously dark-grey. Beneath the forewings are rather dark slate-grey; with a submarginal row of almost obsolete dark dots, a hardly distinguishable, irregular, darker line through the disc; inwardly from the latter the wing is strewn with lighter atoms. In contrast with *augustus*, the hindwing exhibits beneath near the distal margin a white line followed by a band which is composed of dispersed, black, small scales, proximally from it a series of round, white spots or dots, each of which exhibits some black atoms; proximally from it a not very distinct light, dark-tinged line. From Arizona.

hadros. **Th. hadros** Cook & Watson. ♂ above brown, ♀ bright rusty-red with a copper-lustre, towards the margin and the base somewhat clouded. Fringes one-coloured, only near the apex with a white margin. Beneath dark-brown, the hindwings towards the margins dusted in grey, the broadest at the anal angle, otherwise marked like *irus*, mostly only faintly indicated; on the hindwings in the centre of the costal margin with a white diffuse spot; on the forewings stands a whitish postdiscal. Expanse of wings: 32 to 38 mm. — Texas.

Th. irus *Goldt.* (153 h) is above unicolorously greyish-brown, beneath almost just the same as the *irus*, preceding, more blackish-brown; the transverse lines of both wings have a distal white tinge at the costal margin. In the large, more southern form **arsace** *Bsd.* there appear reddish-lustrous spots before the anal part of the hindwings. Distributed in North America. The larva lives on the plum-tree.

Th. mossi *Edw.* (= *polios* *Cook & Watson*) extremely resembles the preceding; beneath the marginal area of the forewing is not brightened up, the dark basal area of the hindwing somewhat more extensive, distally bordered by a fine white line which is often very broad so that it may grow to a band of the colour of a grey-horse of about 2 mm width; the distal part is more indistinctly marked. Widely distributed from New Jersey, New Hampshire, Nova Scotia, Colorado, Canada, Vancouver.

Th. henrici *Grote & Rob.* which was often disputed by American authors with respect of its right of being regarded as a species, differs above by broad distal margins of a copper-reddish tinge; beneath the blackish-brown basal part is sharply and very irregularly defined, often distally accompanied by a complete, white line. From Maine to West Virginia, rather rare. The larva lives just like the preceding. — f. **solatus** *Cook & Watson* from Texas has more uniformly coloured basal and marginal areas beneath, more chocolate-brown and yellowish-brown, above less coppery lustre.

Th. eryphon *Bsd.* (154 f) is above dark brown, on the hindwings in an anal direction warming into copper-brown, fringes white-speckled. Beneath red-brown, on the hindwings more lilac-brown with purple-brown dentate lines, the proximal one bordered proximally by white, the distal one distally, with similar, small marginal spots and, in front of them, pointed, proximally black triangular spots. Distinguishable from the following, very similar species by the postdiscal being almost rectilinear on the forewing. California, Colorado.

Th. niphon *Hbn.* (154 f) is above and beneath extremely similar, but on the forewings beneath, the postdiscal projects sharply outside on the lower radial vein. The larva lives on pines. Nova Scotia to Colorado.

34. *Dolylas*-Group.

Th. dolylas *Cr.* (150 e). Above pale lilac-blue with very broad blackish-brown margins, in the ♂ with a very large, deep rust-brown, black margined scent-spot in the centre of the forewing. Beneath white towards the border yellowish with several blackish and brownish-yellow transverse markings. Widely distributed; from Guiana, Colombia, Bolivia, the Amazon.

Th. spurius *Fldr.* (= *dolosa* *Stgr.*) (150 f) is above, except extensively lighter hindwings, with a broad white costal margin and quite a narrow black distal margin, almost like the preceding, but it has no small tail and the scent-spot seems to be throughout lighter brown. Colombia.

Th. hypocrita *Schs.* (153 h) has neither a tail; above the blue is somewhat more extensive, the border of the hindwing equally broad black. Beneath the proximal part of the forewing as far as the border is broad blackish-brown, the costal base whitish, somewhat clouded in brown, the hindwings more yellow, the post-discal and submarginal brown transverse lines are united analwards and terminate into the anal angle. Mexico, Costa Rica.

Th. ellida *Hew.* (150 e) resembles the preceding above, is darker lilac-blue with a broad black apex of the forewing, rusty-yellow to brown fringes and without a scent-spot; HEWITSON describes such a scent-spot, but I am unable to find it. The hindwing exhibits in front of the border, in an anal direction, 3 small black spots. Beneath the ♀ is like the preceding, the ♂, however, much more variegated by the deep red-brown of the bands and of the triangular basal spot of the hindwing. Venezuela to South Brazil.

Th. malina *Hew.* (150 e) resembles *dolylas* above, but it has quite a different scent-spot: the larger part in the cell is dark-brown, the smaller part placed obliquely above and distally from it is more greyish-brown, the whole spot is surrounded distally by greenish-grey. Beneath brownish, towards the distal margin reddish ochreous-yellow with several brown, narrow bands being convergent towards the anal end on the hindwings. Brazil, Sao Paulo.

Th. palegon *Cr.* (= *myrtillus* *Cr.*, *juicha* *Reak.*) (150 d, c) is allied to the preceding species, above silky-glossy greyish-violet with much narrower margins and only a small, but likewise double scent-spot, the ♀ dull greyish-brown. Beneath the distal margin is brighter rusty-yellow, the proximal surface dusted with violetish-grey, the bands more dentate. From Mexico to South Brazil, common.

Th. cyrriana *Hew.* (153 h) greatly resembles the preceding according to the figure and description; above the black distal margin and apex are entirely absent, the small scent-spot is red-brown, the tail much smaller. Beneath the wings are marked as in *palegon*, but quite brown, the hindwings darker clouded, without the rusty-yellow border. Described from Peru.

Th. nannidion *Burm.* is said to resemble above *Th. lausus* (154 e) in size and colour; forewings brown, hindwings light-blue like there, the under surface is said to approximate that of *palegon*, but to be lighter grey with fainter, posteriorly shortened, brown bands without the rusty-yellow marginal part. Immediately recognizable by the very long, 3rd palpal joint. Argentina (Corrientes).

jada. **Th. jada** Hew. (150 f) we include here as the nearest ally of *malina*. Above lilac-blue with a very broad apex of the forewing, a red-brown anal lobe and small tail, fringes white; at the cell-end a slightly visible black streak-spot, the scent-spot being absent; the ♀ is coloured just the same except a somewhat rounder shape of the wings. Beneath yellowish-white with olive-brownish lines, similarly marked as *malina*. Common in Mexico and Guatemala.

calesia. **Th. calesia** Hew. (150 f) resembles somewhat *ellida* (150 e), but it might more correctly be placed beside *commodus* (153 g) in the *arria*-group. Above greenish-blue with a broad black apex and margins with 2 rather long tails beside the extended anal lobe; without a scent-spot. Beneath red-brown with deep dark-brown markings which are partly finely bordered by bluish-white; in the middle of the costal margin and of the border there is one larger, light, yellowish-brown patch each. Venezuela, Ecuador, Colombia.

35. Dinus-Group.

dinus. **Th. dinus** Hew. (150 f) is known to me only from the description and figure, for which reason its position here is dubious. Shape about that of *elongata* (150 f) or *commodus* (153 g), above similar, without a scent-spot. Beneath red-brown, on the forewing with a large brown triangular spot in the middle of the costal margin, and brown spots in front of the border; hindwing clouded in a darker brown, margin more rusty-yellow, a brown spot near the costal base and two macular bands behind the middle. Surroundings of the black anal lobe dusted in white. Described according to a ♀ from Brazil.

36. Amyntor-Group.

a) tailed species.

amyntor. **Th. amyntor** Cr. (= *menalcas* Cr.) (153 i). Above deep metallic indigo-blue, towards the margin gradually warming into the moderately broad, blackish-brown margin; anal lobes red-brown. Beneath brilliantly green, the proximal margin of the forewing grey; hindwing with a rudimentary row of lunular spots behind the middle, dark cherry-red, to black, distally white-pupilled, mostly there is at the costal margin only one, and analwards 3 or 4 eye-spots; between, below and above the median veins, in front of the border, are yet 3 small cherry-red spots, the one in the middle being the largest. Forehead metallic-green. Abdomen above indigo-blue, beneath yellowish. The ♀ is in the basal half dull greyish-blue, distally blackish-brown. Mexico to Brazil, rather rare.

sicrana. **Th. sicrana** Jones (153 i). I am unable to decide whether this animal is of a different species from the preceding. The description coincides with it except the forehead being described as brown, with metallic-green scales and a white spot between the antennae. The figure exhibits the hindwings beneath marked with larger white spots nearer to the border. Castro (Paraná).

chloris. **Th. chloris** Hew. (153 i) is described according to but 1 ♀; nor do I know it; it looks above alike, but, according to the figure, it seems to have 2 longer tails and a long-stretched anal lobe; beneath the postdiscal macular series of the hindwing is entirely black, distally not bordered by white. Brazil.

herodotus. **Th. herodotus** F. (= *leucania* Hew.) (153 i) is smaller, above duller indigo-blue with quite a narrow, black margin and few scent-scales in the upper cell-corner at the rising of the uppermost radial. Beneath green, equally, but much more finely marked than *amyntor*, the white macular line is mostly more complete, forehead metallic green. From Mexico to the Amazon at altitudes of up to 3000 ft., everywhere common. — In Argentina flies: **Th. acastoides** Berg (= *acaste* Burm. nec *Prittw.*) differing by its larger size, the undulated brown marginal band of the hindwing beneath and a brown-tinged, white macular band.

fusius. **Th. fusius** Godm. & Salv. (153 i) differs merely by the brown colour of the upper surface. Mexico to Panama.

bertha. **Th. bertha** Jones (153 i). Distal margin of the hindwing more straight, not so inflated, anal lobe not developed. Above dull indigo-blue, beneath not to be mistaken for any other species by the peculiar, white-dusted median band. Paraná, Rio Grande do Sul.

pastor. **Th. pastor** Btlr. (154 a) is easily distinguishable by the uncommonly lustrous deep blue colour above, beneath by the brown lunular spots on the margin of the hindwing. The ♀♀ entirely resemble above those of the other species. Mexico to Panama.

b) untailed species.

longula. **Th. longula** Hew. (154 a) has above the same magnificent *Morpho*-blue as *pastor*, but a somewhat broader black margin and a longer extended anal angle. Beneath the green is tinged somewhat ochreous-yellowish; the macular band as in *herodotus* (153 i), only much less visible and inwardly darker shaded; between it and the border there runs a second nebulous band; at the base of the hindwing is often a brown spot of a variable size. Forehead brown, abdomen beneath yellow. The ♀ is above dull greyish-blue, with broad blackish-brown margins. From Colombia, Ecuador and Bolivia.

agricolor. **Th. agricolor** Btlr. (154 a). Shape of the wings similar to that of *bertha*; above coloured like *herodotus*, beneath differing from all the others by the hindwings being broadly marked in red-brown at the base and at the margin and being dusted in white; besides they exhibit in the centre yet a strongly undulated band. Mexico to Panama.

Th. acaste *Prittw.* (= *lycimna* *Hew.*) (154 a) entirely resembles *herodotus* (153 i) except the absence *acaste* of the tail, but on the hindwing beneath, it exhibits a complete and scarcely interrupted, fine, white transverse line, being proximally mostly tinged with cherry-red; there is often also a white discal streak. Brazil (Sao Paulo, Rio Grande do Sul, Sta. Catharina).

Th. remus *Hew.* (154 b) is above more greenish-blue; beneath the transverse band of the hindwing *remus* consists of small red-brown spots, of which only the lowest is white-pupilled; close before the border there is yet a row of small black, white-dusted spots. The ♀ is above greyish-blue, beneath more richly marked in red-brown, as far as to the costal-marginal angle of the hindwing; also on the forewing there are behind the middle of the costal margin small red-brown spots. Brazil.

37. *Dumetorum*-Group (*Callophrys* *Billb.*).

Th. dumetorum *Bsd.* (= *viridis* *Edw.*) (154 b) replaces our *Th. (Callophrys) rubi* in North America. *dumetorum*. Above blackish-brown, in the ♂ with a smooth oval spot at the cell-end, fringes whitish, at the anal angle brown. Beneath deep green except the proximal margin of the forewings being brownish-grey; the proximal margin of the forewing red-yellow; both wings are traversed by a curved band of oblong, white small spots. — The egg is deposited on the flower-buds of *Hosackia argophylla*, but the larva is not yet known. California, Rocky Mountains.

Th. affinis *Edw.* does not differ above, but beneath it is quite unmarked green. Utah. *affinis*.

Th. apama *Edw.* from Arizona is above like *dumetorum* (154 b), beneath marked almost like *castalis*; *apama*. untailed. Above blackish-brown with an oval, black stigma; beneath the forewings are yellowish-brown, in the apical area and at the costal margin golden-greenish; in the disc a transverse row of small spots consisting of black, distally white-tinged, proximally red-brownish-tinged, small streaks. On the hindwings there is a discal, somewhat irregular row of similar spots of which those in the costal half are moon-shaped; expanse of wings: 27 mm.

Th. sheridanii *Edw.* is the last species belonging to the „*Callophrys*“-group. It has hitherto been *sheridanii*. exclusively found in the Rocky Mountains.

38. *Janias*-Group.

Th. janias *Cr.* (= *romulus* *F.*, *cecina* *Hew.*) (154 b) is above magnificently deep ultramarine-blue *janias*. with black veins, a broad black apex and a narrower black distal margin. In the upper cell-corner in the apical black a dark brownish-grey scent-spot. Beneath magnificently emerald-green including the thorax, legs, forehead, palpi, borders of the eyes and shoulders. On the hindwing there is a postdiscal transverse line mostly present only analwards and forming here a W, a spot between the median veins, the tail and the white-bordered fringes velvety-black. In the ♀ being above greyish-blue to brown, on the hindwing beneath, the black transverse line is complete as far as the costal margin, also a large black anal spot. — In the form *hassan* *Stoll* (154 b) the *hassan*. black spots above are bordered by a broad orange-red. Most widely distributed from Mexico through the whole of Central America as far as Guiana, Colombia, Bolivia, the Amazon, and South East Brazil.

Th. esmeralda *Jones* (154 b) is closely allied to the preceding, but it has above much broader black *esmeralda*. margins; beneath the hindwing exhibits a fine, black, undulate postdiscal line, being the most distinct at the proximal margin. The spot between the median veins is quite orange. The ♀ is above brown with a faint lilac-grey lustre; beneath the black undulate line is more distinct, the orange spot larger, a second one is at the anal angle. Castro (Paraná).

39. *Thabena*-Group (= *Jaspis* *Kaye*).

Th. thabena *Hew.* (154 b). Above brilliant blue with a large black scent-spot in the cell of the fore- *thabena*. wing, a narrow black margin and a somewhat broader apex; beneath light-grey with 2 fine transverse lines, the proximal one inside bordered by orange, outside by white and beginning at the margin of the hindwing with a distally arranged, large black spot, strongly dentate; anal angle extensively yellow. The ♀ is above dark brown, at the anal angle of the hindwing and at the proximal margin white-spotted. Surinam to the Amazon.

Th. temesa *Hew.* (154 c) is beneath almost like *thabena*, but above very dark ultramarine-blue *temesa*. with a brown oval discal spot. Guiana to the Amazon.

Th. talayra *Hew.* (154 c) is above brilliant-blue, bordered like *thabena*, but with a small scent-scale- *talayra*. spot of the same colour at the upper cell-end. The under surface is lighter, almost white, the line-markings the same, but at the anal angle two orange-red spots. Common from Mexico to Brazil. — From Pará and Espiritu Santo the f. *castitas* *Drc.* (154 c) is described with a much duller, more greenish blue and a somewhat broader *castitas*. black margin; the under surface is darker, at the anal angle more red.

- beera*. **Th. beera** Hew. (154 c). More violettish-blue than the preceding with a broader black margin and a larger scent-spot; beneath darker grey, the line-markings the same except the costal-marginal spot of the hindwing being more streak-shaped; anal-angular spots smaller. Ecuador, Brazil.
- exiguus*. **Th. exiguus** Drc. (154 c) is marked like the preceding, but above more indigo-blue with a greenish tinge and without any scent-spot; beneath like the preceding. Surinam.
- castimonia*. **Th. castimonia** Drc. (154 c) is above as blue as *beera*, but without the scent-spot and with but quite a narrow black distal margin without getting broader at the apex and with a distinct red anal spot also above; the under surface is lighter with but little red at the anal angle of the hindwing. Colombia.
- pura*. **Th. pura** sp. nov. (154 c) is very well to be included here. Above unicolorously blackish-brown, the hindwing at the anal angle with a small yellowish spot and a short white marginal line before the otherwise black one. Beneath silvery-white with an extremely fine brownish postdiscal showing the same course as in *beera*, but being placed somewhat more into the centre of the wing; also the small spot being placed distally at the costal margin of the hindwing is very small and fine. There are no submarginals at all, only at the anal angle stands a tiny yellow spot being above bordered by black, next to it the traces of a blackish crescent. Described according to 1 ♂ from Sao Paulo.

40. Meton-Group (*Rekoa* Kaye).

- meton*. **Th. meton** Cr. (= *metus* Hbn., ♀ *augustus* F.) (150 d) on the one hand resembles *palegon*, on the other hand it forms the transition to the following group. The ♂ is above of a delicate light-lilac with a white scent-spot, the ♀ almost white. The under surface is light-yellow to rusty-yellow with similar lines as in *malina* but an eye-spot in the middle of the costal margin of the hindwing. From Mexico to Colombia and Brazil, everywhere very common.
- phrynisca*. **Th. phrynisca** Burm., perhaps a form of the preceding, is somewhat smaller, the forewings above much more extensively black, beneath at the costal margin of the hindwing there is no eye-spot. Described according to 2 ♀♀ from Argentina (Corrientes).

41. Mazurka-Group.

- atesa*. **Th. atesa** Hew. (154 d) is above only in the proximal half of the wings brilliant blue, a round brown scent-spot stands already in the apical black. Beneath light-brown, very peculiarly marked in red-brown with a large black eye-spot in the middle of the costal margin of the hindwing and a bronze-green dusting at the anal angle. Panama to the Amazon.
- mazurka*. **Th. mazurka** Hew. (154 d) is perhaps not allied at all to the preceding, it is only placed here on account of the analogy of the marking beneath. Above the blue is still more reduced in the ♂, a scent-spot is absent. Beneath the eye-like spot at the costal margin of the hindwing is much more developed and exhibits 2 blue pupils. The ♀ is above quite brown. Amazon.

42. Narbal-Group.

- narbal*. **Th. narbal** Stoll is unknown to me in nature. According to the figure and description it must be very closely allied to the following; it seems to be a little larger and has beneath at the base of the costal margin of the forewing and hindwing extensive red spots. Surinam.
- amplus*. **Th. amplus** Drc. (150 k) is above brilliant-blue with a moderately broad black distal margin and a small, blackish-grey scent-spot in the upper cell-corner. Beneath the forewings are brown, unmarked, except the narrow red base of the costal margin; the hindwing exhibits in the middle of the costal margin a black, distally white eye-spot, in front of the border a fine black, distally white undulate line, a black anal-angular spot and next to it a spot strewn with bluish-white. Venezuela, Amazon.
- ophelia*. **Th. ophelia** Hew. (150 k) is very similar, has above broader black margins and a larger scent-spot; beneath the costal-marginal eye-spot is absent, the base of the hindwing is more extensively red, a marginal spot between the median veins is black. Bolivia, Amazon.
- hypsea*. **Th. hypsea** Godm. & Salv. (150 k) differs by a decidedly greener blue above, the distal margin, particularly of the apex, is much narrower black; the scent-spot exhibits at its lower margin a narrow light-brown part. The under surface is as in *ophelia*, but the black marginal spot between the median veins is absent and replaced by only white dusting. Panama. — **stictos** Drc. (151 a) from Colombia I can only take to be a form of *hypsea* with a green upper surface, I do not find any other differences.
- athymbra*. **Th. athymbra** Hew. (150 i) is beneath exactly like *hypsea*, the bases of the wings more chestnut-brown, above the blue is reduced by the very broad black apex, the scent-spot is very large, double, proximally red-brown, distally greyish-brown. Amazon (Itaituba).
- Th. gemma** Drc. (151 a ♂; the figure (150 k) denoted as *gemma*-♀ is wrong, it represents the upper surface of the allied *rocena*) resembles the following species from which it is discernible by the upper surface

exhibiting a deeper purple-blue and an oval, somewhat smaller scent spot. Beneath the ground-colour is of a somewhat deeper tinge, the two small white spots on the forewing bordering on the basal red are absent, and the hindwings exhibit a second red spot at the inner-marginal base. Peru.

Th. minyia Hew. (150 h) is above lustrous blue, of a somewhat greenish tinge, the apical half blackish-brown, in it lies the small round greyish-brown scent-spot. The under surface is ochreous-brown, the bases of the wings red, on the forewings bordered by two, on the hindwings by one white spot, the former two distally, the latter proximally bordered by black; the forewings exhibit yet a white oblique band at the cell-end, the hindwing at the proximal margin the beginnings of a white undulate line, between it and the black anal angle there is some greenish or bluish-white dusting. French Guiana to the Amazon. *minyia.*

Th. porthura Drc. (150 h) is above deeper ultramarine blue, the scent-spot is placed in the dark purple-blue. The under surface is more ochreous-yellow on the hindwings, the forewings are without the two small white basal spots, but on the hindwing a black, bluish-white-ringed eye-spot borders on the basal red, the black, distally white postdiscal extends as far as to the centre of the wing, and mostly there is even yet a small white spot at the costal margin, the anal angle is more extensively green. Panama to Colombia. *porthura.*

Th. rocena Hew. (150 k a *gemma*-♀) has no scent-spot, but such a broad black costal margin that the deep violettish-blue remains confined to the basal inner-marginal half of the forewing. Beneath similarly marked as the preceding, but the ground more greyish-brown. Below the cell of the forewing is a large black spot; behind the cell, between the lower radial and lower median veins, there is a white arcuate line; the anal angle of the hindwing extensively strewn with metallic green, between the median veins a jet-black spot bordered above by orange. Colombia to the Amazon. *rocena.*

Th. fessa Mschlr. described only according to 1 ♀, seems to me to belong here. Above dark-brown, towards the base with a bluish-grey tinge. Under surface yellowish-brown, marked almost like *atena* (150 h), but the forewings without any marking, the hindwing with the costal-marginal eye-spot of *amplus* (150 k) and its allies, but without any basal red; farther outside there is another smaller white dot bordered distally by black; postdiscally, towards the proximal margin, a white, towards the base black undulate line, towards the margin whitish-blue dusting, at the anal angle a black spot being yellow towards the base. Surinam. Forewings 15 mm long. *fessa.*

Th. atena Hew. (150 h) is above brilliant-blue, towards the margin suffused in purple with a round, brownish-grey scent-spot in the upper cell-corner, and a broad black apex. Beneath like the preceding, but on the forewing a white oblique band at the cell-end, proximally bordered by black, forming on the lower median vein an acute angle projecting outside. The markings of the hindwings are bluish white, analwards very much metallic green dusting. Guatemala to the Amazon. *atena.*

Th. geba Hew. (150 h) resembles the preceding above, perhaps of a slightly greener tinge, beneath darker brown, the discal band of the hindwing more developed and especially behind the middle of the cell moved farther towards the base, all the markings a little more intense, the bluish-white still deeper blue. Before me from Bolivia and Colombia. *geba.*

Th. melleus Drc. (150 i) entirely resembles *atena* beneath, but above the blue is much less lustrous and strongly reduced by the apex and also the distal margin of the hindwing being much broader black. The scent-spot is the same. Colombia. *melleus.*

Th. florens Drc. (150 i) is likewise very closely allied to the preceding, on the forewings lustrous and extensively blue as *atena*, on the hindwings lighter blue. Beneath the ground-colour is darker, more leaden-coloured, towards the margin with a coppery lustre; the white line of the hindwing runs more uniformly and is less broken. Amazon (Tapajos). *florens.*

Th. ravus Drc. (150 i) is compared with *minyia* (150 h) by the author, above with a smaller, rounder scent-spot and a lighter, reduced blue. The under surface is brighter red-brown, the white spots bordering the basal-red are absent, so is the red colour on the hindwings, but the costal-marginal eye-spot is present instead. Amazon. *ravus.*

Th. color Drc. (150 i) resembles somewhat *athymbra* above, it is of a more brilliant blue than the latter, without any scent-scales, but with a dark spot in the distal half of the cell. Beneath lighter, almost without any basal red, only faintly tinged lilac-reddish, on the forewings with a postdiscal row of moon-spots, the markings only feebly expressed. Guiana. *color.*

Th. sista Hew. (151 a) initiates a special subordinate group of species resembling each other very much, with a much more slender structure and more delicate wings, partly almost diaphanous. Above brilliant blue with broad black margins and a quite uncommonly large scent-spot of a brown colour, being extended from the distal half of the cell almost to the proximal half of the radial and median veins. Beneath all these species are indiscriminately almost of the same colour and marking, grey with bluish-white transverse lines, on the hindwings broken, forming a W towards the anal part, anal margin lustrous metallic grass-green, in it two black spots bordered above by yellow, at the base of the costal margin of the hindwing an isolated white spot. Guiana, Colombia, Brazil. *sista.*

- aurora*. **Th. aurora** Drc. (151 a) is above much brighter and more extensively blue with a somewhat smaller, black scent-spot immersed in the blue; beneath lighter, more brownish, the markings finer. Brazil (Espiritu Santo, Sta. Catharina, Rio Grande do Sul).
- malvina*. **Th. malvina** Hew. (151 a) is a little larger, above duller violettish-blue with a somewhat broader, black apex than *aurora* and a large, red-brown scent-spot, beneath somewhat browner, the proximal line of the forewing very oblique and consisting of single, small spots. Brazil.
- janthina*. **Th. janthina** Hew. (151 b), with longer, almost diaphanous wings and a violet upper surface with a slight yellowish reflection, has only a small, narrow scent-spot at the lower cell-end on the median; beneath no difference. Guatemala to Brazil.
- armilla*. **Th. armilla** Drc. is coloured above like *janthina* (151 b), but the shape of the wings is that of *sista* (151 a), and the scent-spot at the lower cell-end is more prominent than in *janthina*; the under surface is darker. Rio de Janeiro.
- flosculus*. **Th. flosculus** Drc. (151 b, c) resembles *armilla* above, but the blue is more extensive, with a purple lustre and not so brilliant; the under surface is greyer, the markings more distinct, broader white. Espiritu Santo.
- cydonia*. **Th. cydonia** Drc. (151 b) has the shape of *janthina*, but quite black forewings and a somewhat broader black margin of the cornflower-coloured hindwings. Beneath there is no difference. Colombia.
- mutina*. **Th. mutina** Hew. (151 b) is beneath almost like *sista* of which it has the shape of the wings, but the anal angle of the hindwing has no green, but bluish-white dusting. The upper surface is entirely different, dark blackish-brown, on the proximal margin of the forewing, and in the larger inner-marginal half of the hindwing, it has a deep indigo-blue tinge, without a scent-spot. Guiana to the Amazon.
- mecrida*. **Th. mecrida** Hew. (151 b) has above a somewhat more extensive, more greenish blue, on the under surface there is instead of the small basal, costal-marginal spot of the hindwing a white stripe being distally bordered by blackish-brown and extending as far as the lower cell-angle. — In some cases this stripe is confluent in the middle with the postdiscal dentate-line; this is **anastomosis form. nov.** (151 b). Guiana to the Amazon.
- conoveria*. **Th. conoveria** Schs. is a little larger, above more extensively metallic-blue with a dark spot at the cell-end, but without any scent-scales. Beneath there is hardly any difference, but on the hindwings the postdiscal (median) white line runs straight from the costal margin to the lower median vein on which it is broken; then running in the shape of a W to the proximal margin. Expanse of wings: 24 mm. Petropolis.
- myrtusa*. **Th. myrtusa** Hew. (151 d) resembles the following, but on the hindwing the distal band beneath is absent, on the forewing the white costal -marginal spot is removed more towards the base, and between the red spot of the tail and the anal angle there is extensive, bluish-white dusting. Amazon.
- myrtea*. **Th. myrtea** Hew. (151 b) is very similar, the ♂ above dull violettish-blue with a broad black apex, without a scent-spot, the ♀ dull bluish-grey, distally broad blackish-brown. Beneath brownish-grey, on either wing with two white rows of lunular spots, the proximal one being proximally bordered by black, the distal row distally, the hindwings in the ♂ with a very convex costal margin which covers a red-brown scent-scale-spot on the under surface of the forewing below the median. Marginal line subtile black, proximally white; between the tails an orange-red, black-pupilled spot, a smaller one at the anal angle, between them some white dusting. Colombia, Bolivia, Amazon.
- malvania*. **Th. malvania** Hew. (151 c) is larger, more lustrous metallic blue, but only in the basal third of the forewing; the costal margin of the hindwing broadly brown, the distal margin narrowly black. Beneath it resembles the preceding, but the white costal-marginal spot of the hindwing is removed more towards the margin as the beginning of the white postdiscal, the costal margin is less convex, and the forewing is without the distal macular line. The 3 last species might also be placed in the corresponding subordinate group of the *sichaeus*-group. Amazon.
- bianca*. **Th. bianca** Mschlr., described according to a ♀ being closely allied to the preceding, has remained unknown. Above dark-brown, towards the base greyish blue, on the hindwings more extensive. Beneath greenish-grey, the postdiscal on the forewing consisting of separate, white, towards the base black, small spots, on the hindwing continued as a strongly broken stripe; submarginal, white, towards the margin black, small spots; spot of the tail oval, red, bordered by yellow; anal spot black, between both bluish-white dusting. From Surinam.

43. Polibetes-Group.

- polibetes*. **Th. polibetes** Cr. (= zoe Reak.) (152 c). This and the following species all exhibit a black or black and white costal-marginal spot near the base of the hindwing beneath. Above deep blue with a moderately broad, sharply delimited costal margin and distal margin and fine black veins and a large black median spot;

in the upper cell-corner is a round, brownish-grey scent-spot varying greatly in its colour, close below it a smaller, crescentiform, blackish-grey one and between both a reddish-brown, fine row of scales. The ♀ is more greenish-blue, with a much broader, blackish-brown border. The under surface is extremely variable, lighter or darker brown with a violet lustre, on the forewing an arcuate or straight line or row of spots, in front of the border blackish spots; on the hindwing, beside the basal dot, a curved row of spots, with a distal silvery-blue tinge, behind it a row of spots and between the tails a red, black-pupilled spot. — In *sedecia* Hew. (152 i) the line *sedecia* of the forewing is straight, distally, like all the spots anyhow, with a broader bluish-white tinge. Common from Mexico to Brazil.

Th. thyrea Hew. (152 f) is somewhat larger, the blue greatly reduced by very broad black margins, *thyrea*. without the large black median spot, the single brown scent-spot surrounded by black. Beneath almost like *polibetes* (152 c), but of a more intense violet, the proximal margin of the forewing extensively yellowish-grey, on the forewings the macular band in front of the border is absent. Abdomen beneath yellow. The ♀ is above dull greyish-brown with broad blackish-brown margins, the under surface more grey with an orange tinge. Panama to the Amazon.

Th. arindela Hew. (152 b) has above more extensive greenish-blue, so that the scent-spot is situate *arindela*. in the ground-colour. Beneath the white macular lines are more developed, on the forewing there are beside the postdiscal yet two nearer to the proximal margin. Abdomen above greenish-blue, beneath orange. Nicaragua.

Th. epytus Godm. & Salv. (152 c) resembles above more *thyrea* (152 f) by the scent-spot being situate *epytus*. in the black, beneath the forewings are without markings, the hindwings as in *orgia* (152 e) with a dark discal streak of the hindwing. Panama.

Th. stigmatos Drc. (152 b) resembles *arindela* above, but it has a more obtuse and broader black *stigmatos*. apex of the forewing; the under surface is almost like in *orgia*, but the forewings are without any markings at all. It originates from the interior of Colombia.

Th. orgia Hew. (152 e) looks above like a small *polibetes* without a black median spot, the scent-*orgia*. spot is remarkably light. The ground-colour of the under surface is more yellowish-brownish, otherwise equally marked. Common from Mexico to the Amazon.

Th. m-album Bsd. (= *psyche* Bsd.) (152 d) for which SCUDDER has established the genus *Eupsyche*, *m-album*. is more slender, otherwise above like *orgia* (152 e), but with a distinct red anal spot of the hindwing and somewhat lighter blue. Beneath also marked the same, but the postdiscals form coherent white, proximally brown-bordered lines with a distinct W at the proximal margin. The red anal-angular spot is large and sends a connecting stripe towards the red tail-spot, between both there is bluish-white dusting on a blackish-brown ground. The range of the species extends from the Southern States (New Jersey, Wisconsin) to Venezuela. — The larva lives on *Quercus* and *Astragalus*.

Th. ostia Hew. (152 d) likewise resembles above *orgia* (152 e), but it is somewhat more greenish-blue *ostia*. and has an extensive black apex of the forewing. On the under surface the white macular bands are moved much nearer to the border, and on the hindwings they run more uniformly bent, parallel to the margin; the red spots are well developed. Brazil.

Th. vibidia Hew. (= *socigena* Hew.) (152 c) greatly resembles the preceding, above darker purple-*vibidia*. blue, the scent-spot more oblong, red-brown. The under surface, particularly of the hindwings, is darker brown, and here the proximal white macular band begins at the costal margin with a distally removed spot; the red spot between the tails appears to be placed more inside. Mexico to the Amazon.

Th. hecate Godm. & Salv. (154 d) from Mexico and Nicaragua is very closely allied, deeper blue, *hecate*. with a more distinct stigma. The forewings bear a discal line beneath.

Th. hewitsoni Ky. (= *ira* Hew.) (152 d as *ira*) greatly resembles *ostia* above, but the distal margin *hewitsoni*. of the hindwings is only quite narrowly black, the scent-spot is smaller. Beneath the markings are more obsolete, the white lines finer, the forewings without any markings at all. Mexico.

Th. punctum H.-Schäff. (152 d) is smaller, more compact, with rounder hindwings, coloured like *punctum*. *m-album*, but without any red at the anal angle. Beneath coloured like *m-album*, the white macular band in front of the border of the forewing quite obsolete, on the hindwing removed very far towards the margin, the red spots intense, mostly connected. In the ♂ the white dot in the middle of the costal margin of the hindwing is very minute or it is absent altogether, in the ♀ being above dull greyish-blue it is more distinct. Guiana to the Amazon.

Th. nitor Drc. (152 h) is perhaps only an aberration of *punctum* with beneath unmarked forewings *nitor*. and almost absent submarginal spots on the hindwings, on which the proximal macular band is more distinct and more coherent. Amazon.

- fancia.* **Th. fancía Jones** (152 b) closely allied to the preceding is above brilliantly metallic-blue with a greenish lustre in the basal half. The under surface is more yellowish-grey, the submarginal macular band of the forewing is more distinct, distally broad white, reaching down as far as the lower median vein, on the hindwing the proximal macular band is placed not so near to the margin, the spot of the tail is smaller, orange. Castro (Paraná).
- echella.* **Th. echella Hew.** (152 f) is another stage of development of *polibetes* (152 c) in which there appears a broad black discal band on the fore- and hindwings; in the upper cell-corner is the small round red-brown scent-spot. The under surface is lighter reddish-brownish, the marking almost as in *vibidia* (152 c). Amazon.
- phoenissa.* **Th. phoenissa Hew.** (152 e) we include here; above like *thyrea* (152 f), somewhat duller indigo-blue with a greenish shine, the veins of the forewings broader black, the scent-spot somewhat larger. The ♀ is duller greyish-blue with a dull metallic lustre. The under surface makes the species very easily recognizable by the abundant white marking. From Nicaragua, Panama, Colombia to the Amazon.
- selica.* **Th. selica Hew.** (152 c) somewhat resembles *m-album* (152 d) beneath, but between the postdiscal lines and submarginal macular bands it has on each of the wings a straight broad band of bluish-white dusting inserted; on the hindwing the costal-marginal spot has turned a streak, and often, particularly in the ♀, there are in the basal area some more bluish-white streak-markings. Above lighter greenish-blue, with a small round brown scent-spot; the ♀ is very similar, duller, with broader margins. Colombia, Bolivia, Brazil.

44. Rustan-Group.

- rustan.* **Th. rustan Stoll** (= *macaria Sws.*) (152 a) has very close relations to the preceding group. The ♂ is above dark-brown, only in the basal inner-marginal half of the forewing it has a dull blue tinge, with red-brown fringes, on the hindwing analwards a black marginal line and white hair at the anal lobe. The scent-spot is extremely complicated: at the cell-end a dark-brown round spot, in which there is distally a light fawn-coloured sector; behind the cell a four-cornered black spot, the proximal one is yet surrounded by slate-grey. The ♀ is duller, more extensively greyish-blue. Beneath with very characteristic markings. From British Honduras, Panama to Brazil.
- polama.* **Th. polama Schs.** presumably belongs here. Above dark violettish-blue with a narrow black distal margin with a long scent-spot being parted by a violet line, the proximal half lighter, the distal half darker brown; fringes red-brown. Beneath of a silky-lustrous brown, very similarly marked to *rustan* (152 a), but the spots a little finer, not so thick and more bordered by white; abdomen with a golden yellow, black-margined ventral line. The ♂ exhibits above and beneath darker and duller colours. Petropolis in South Brazil. Expanse of wings: ♂ 35, ♀ 36 mm.
- ortygus.* **Th. ortygus Cr.** (152 a) is above lustrous lilac-blue with moderately broad black margins and only a small brown scent-spot at the upper cell-end; proximal margin and anal lobe almost white, the latter with a black spot. The under surface is very pale lilac-grey with thick black spots arranged in the same way as in *rustan*, but the forewings are without the antemarginal band; the anal angle of the hindwing is extensively greenish and strewn with bluish-white. The ♀ is above coloured the same, but it has broader brown margins. Everywhere common from Mexico to Brazil, also in Trinidad. — In the stony deserts of West Mexico (Guerrero)
- lauta.* there flies a smaller, remarkable form which I denominate: ***lauta form. nov.*** (152 a); it is above lighter lilac, with a milky tinge, beneath with much smaller and dull brown markings that are tending to form more coherent lines.

45. Jebus-Group.

- jebus.* **Th. jebus Godt.** (152 b) is quite an isolated species, above dull steel-blue, with narrow black margins, and particularly in northern specimens with a red-brown anal spot of the hindwing and a small brown scent-spot in and above the upper cell-end. The ♀ is milky greyish-blue, with broad greyish-brown margins. The peculiarly brown marbled under surface of the hindwings makes it impossible to mix it up with other species. From Mexico to South Brazil and Peru, everywhere common.

46. Brescia-Group.

- brescia.* **Th. brescia Hew.** (= *thoana Hew.*) (152 f) is so closely allied to *punctum* (152 d) and its nearest allies that it must be made optional to the individual observer whether he prefers to range *punctum* into this family or not. Above lustrous blue with moderately broad black margins and a small, round, light-brown scent-spot at the upper cell-end, anal lobe orange. The ♀ is above greyish-brown, distally broad darker brown. The under surface is greyish-brown with a lilac reflection, marked almost the same as *punctum*, on the forewings with a distinct postdiscal band. Mexico to Nicaragua.
- orses.* **Th. orses Godm. & Salv.** (152 g). Like the preceding, with a broader black apex of the forewing and beneath at the anal angle with ochreous-yellow spots, not red ones. From Guatemala.

Th. ligurina Hew. (152 e) is deep steel-blue with a purple tinge, with a small brown scent-spot *ligurina*. at the cell-end, the ♀ greyish-blue with dark-brown, broader margins. Beneath ashy-grey, forewings without any markings, hindwings marked as in the preceding species, but the proximal band at the costal margin is placed more towards the base. Mexico to Panama.

Th. chlamys Drc. (152 g). Above like the preceding, but with a red-spotted anal lobe; beneath more *chlamys*. reddish, the red spots of the hindwing less developed, and the proximal white line less sinuous. The ♂ is above brown, in the disc greyish-blue. Paraguay.

Th. lyde Godm. & Salv. (152 f) is above metallic indigo-blue, the broad black apex and the narrow *lyde*. distal margin gradually pass over to the blue colour. The scent-spot at the cell-end is rather large, brown, bordered by an elevated, metallic greenish-grey ring; the anal lobe of the hindwing without any red. The ♂ is only little duller blue. Beneath ashy-grey, marked like the preceding species. Mexico to Panama.

Th. ergina Hew. (= *ela* Hew.) (152 e) is somewhat larger, otherwise above like *lyde*, also beneath *ergina*. alike, only more faintly marked, but of a light brownish ground-colour; the red spots of the hindwings larger, their black pupil smaller. Surinam, also from Jamaica.

Th. voltinia Hew. (152 k) is still larger, above deep indigo-blue with a greenish lustre and a large, *voltinia*. roundish, brown scent-spot with a greenish slate-colour floating round it, on the anal lobe a reddish spot; beneath darker brown than *ergina*; the two submarginal macular bands are closer together. Brazil. Bolivia.

Th. buccina Drc. (152 h) differs above from the preceding by a deep steel-blue colour, similarly as *buccina*. in *ligurina*, and an entirely circular scent-spot; the ground-colour beneath is a warm red-brown, the two white lines of the hindwing are still closer together. Brazil.

Th. zebina Hew. (152 f as *zelina*) is also in the ♂ above bluish-grey with a roundish dark scent-spot *zebina*. and dark spots before the distal margin of the hindwing; anal lobe with red spots. The ♀ is above lighter, between the tails also above with a red, black-pupilled spot. Beneath light brownish-grey, on the hindwings similarly marked as in the preceding species, but the white lines are more remote from each other, the orange-red spots are very large and between them there is bluish-grey dusting; the forewings likewise exhibit 2 white, ante-marginal macular lines. Mexico to Nicaragua.

Th. guadala Schs. is allied to *brescia* (152 f) and seems also to approximate *zebina*; I only know it *guadala*. from the description: above distinguishable by the metallic steel-blue colour, the black scent-spot at the cell-end being somewhat oval, the anal lobes likewise spotted in red. The ♀ is in the basal third bluish-grey, distally blackish-brown; hindwing at the distal margin spotted in black, anal lobe red. Beneath dark grey, marked like *brescia*. Mexico (Guadalajara). Expanse of wings: ♂ 30, ♀ 28 mm.

47. Cupentus-Group.

Th. cupentus Cr. (= *annulatus* Gmel.) (154 d) has the same scent-spot as *lyde* (152 f) and its allies, *cupentus*. but it is larger here and placed nearer to the base by the very short cell. The forewings are above brownish-black, proximally strewn with metallic blue. The under surface is brown with white transverse bands and on the hindwing a white discal streak forming a sling with the proximal band; between the tails an orange-brown, black-pupilled spot. Distributed from Nicaragua to Brazil, mostly common.

Th. comana Hew. (= *peralta* Mschlr.) (154 c). The ♂ is above greyish-blue with a slight lilac lustre *comana*. and a broad black apex; scent-spot double, obliquely overlapping each other as in *thyesa* (152 g), beneath dark-brown, distally reddish-brown. The ♀ is brown, towards the base with a slight greyish-blue tinge with a red, above white-pupilled spot at the anal angle and proximally fine white, black marginal line. Beneath quite similar to *cupentus* (154 d), yellowish-brownish, on the hindwings with a lilac shine. On the forewings the proximal band extends only as far as the lower median vein and grows narrower costally; on the hindwings the red spot between the median veins is removed more inwards; all the markings are more indistinct, more blurred. Brazil.

Th. cambes Godm. & Salv. (154 e) is rather similar, above the pale lilac-blue is very much reduced, *cambes*. on the forewings confined to the basal inner-marginal part; the fringes, particularly on the hindwings, are more rusty-brownish. The lower part of the scent-spot is oval, jet-black, the upper part very small, about crescentiform, brownish-grey, both parts embedded in a greyish-blue scaled ring. Beneath very much like *comana*, easily recognizable by the broad, lilac-white dusting of the costal angle of the hindwing; on the forewings the postdiscal white band is united with the proximal submarginal band on the lower median vein. Mexico, (Jalapa), Guatemala.

Th. molena Jones (154 e). The ♂ is above subdued dark metallic blue, the distal margin and apex *molena*. of the forewing broad black; in and behind the cell is a large oval, black scent-spot, parted by the blue transverse vein; anal lobes of the hindwings red. The under surface is brown with a lilac shine on the hindwings

and in the marginal area of the forewings; the markings like in the following species, but more faded and more indistinct. The ♀ is above brown, in the basal area suffused by violettish-blue, beneath less lilac. Castro (Paraná).

lemona. **Th. lemona** Hew. (154 e), described only in the ♀, is larger, above greyish-brown, distally dark-brown. Beneath greyish-brown, on the forewings a postdiscal, straight, white band and two antimarginal rows of white lunular spots, particularly distinct towards the apex. Hindwings with a white undulate median line, at the cell-end in front of it 2 white streak-spots as in *cupentus*. Marginal area marked like on the forewings; the anal spot and a spot being pushed in more proximally between the median veins black, bordered above by red. Brazil.

lausus. **Th. lausus** Cr. (= *libanius* Cr.) (154 e) undoubtedly has close relations to *cambes*, for which reason we include it here. Above it resembles the said species, of a purer and more extensive milky lilac-blue, the scent-spot almost as it is there, but the upper brownish-grey part nearly just as large as the lower one, being deep velvety-black. The ♀ is duller and almost whitish. Beneath purple-brown with broad, purely white markings, on the hindwings arranged almost as in *cambes* with a very prominent white trapezoid-spot at the costal angle; the spot of the anal lobe is quite black. Distributed from Nicaragua to the Amazon.

48. Mycon-Group.

mycon. **Th. mycon** Godm. & Salv. (152 g). Above extremely lustrous ultramarine-blue with a very large, cinnamon-brown scent-spot filling up half the cell, and a narrow black margin. Beneath light greyish-brown with a very fine, proximally brown, distally white discal stripe being broken on the hindwing and forming a W at the proximal margin; in front of the border there are indistinct, small lunular spots, between the median veins a large red spot being proximally more yellow, distally black-pupilled; between this spot and the anal lobe being distally black, then white and proximally reddish-yellow, there is bluish-white dusting on a brown ground. The ♀ is above brown, towards the proximal margin, particularly on the hindwings, spread over by a pale blue. From Mexico to Colombia. The southern form from Brazil (Rio Grande), **murex** Drc. (152 h), is somewhat darker and duller blue with a larger scent-spot and a broad black margin, beneath lighter with a less angled discal stripe.

49. Thyesta-Group.

thyesta. **Th. thyesta** Hew. (152 g) and its nearest allies exhibit some resemblance to the *brescia*-group in the marking beneath, but the linear markings are finer and more streak-like. The shape of the wings and the upper surface is quite different: above metallic indigo-blue with a broad black apex of the forewing and costal margin of the hindwing. The scent-spot is double: the part in the cell is black, obliquely outside above it is the distal brown part which is not at all reproduced in the badly executed figure. The under surface is greyer than in the figure, the W ought to be placed nearer to the proximal angle. Colombia, Amazon.

caninius. **Th. caninius** Drc. (154 e) differs from the preceding by almost entirely blackish-brown forewings, only the proximal margin is strewn with blue, also the hindwings are opalescent blue only in the inner-marginal half. The under surface is browner, the markings fainter, placed nearer to the border and without any white dusting before the anal angle. Venezuela, Bolivia.

pharus. **Th. pharus** Drc. (152 k) is larger than *thyesta*, also the scent-spots larger and more intensely prominent; the blue has a somewhat greenish tinge and is more extensive than in *caninius*. The under surface is darker, the lines straighter. Amazon (Pará), Bolivia (Songo).

radiatio. **Th. radiatio** Drc. (152 k) has the same scent-spots, but quite black forewings, and on the hindwings also only the disc is purple-blue. The under surface is dark-brown, the forewings almost without any markings. At the anal angle the red spot is absent. Amazon.

munditia. **Th. munditia** Drc. (152 i). In this species only the distal brown part of the scent-spot is present, the black spot in the cell-end is visible in an oblique exposure to light, but it does not contain any scent-scales; it is a very small species, the blue as extensive as in *caninius*, but more slate-blue. Under surface reddish-grey, in the ♀ lighter, with the markings of *thyesta* (152 g). The ♀ is above unicolorously brown. British Guiana.

jactator. **Th. jactator** Drc. (152 i) entirely resembles *thyesta* (152 g) beneath, but it differs greatly above: on the blackish-brown forewings with a radiantly blue proximal part there is at the cell-end a rather large, deep velvety-black scent-spot; hindwings likewise blue with a black distal margin of about 1 mm width. Paraguay.

50. Avoca-Group.

avoca. **Th. avoca** Hew. (154 f) is above lustrous blue with a green reflection, dark-brown margins and a small, round, red-brown scent-spot. Beneath red-brown with a violet purple tinge, with a postdiscal white macular band and small, whitish-dusted antimarginal spots of the forewings. Hindwing in the larger anal

half lilac-white with a submarginal brown macular band and an orange spot between the median veins. In the purple-brown basal half there is a white macular band before the centre and behind it a second one being broadly dusted in grey on both sides. Amazon.

Th. olbia Hew. (154 f) has a larger, double, proximally black, distally brown scent-spot and the *olbia*. ground-colour is a purer sky-blue with a very broad blackish-brown apex. Beneath the forewings are reddish-brown-grey, towards the distal margin densely dusted in white with the same lines as the preceding, and a white discal streak; the hindwings are silvery white, densely clouded in brown, with an indistinct brown, distally white-bordered, undulate median band. Amazon. — In the form **phallica** Hew. (154 f) the white dusting beneath is almost entirely absent. *phallica*.

Th. erema Hew. (= *biston* Mschlr.) (154 f) exhibits above a somewhat more violet tinge in the *erema*. still more reduced blue and has a very complicated, uncommonly large scent-spot filling up almost the whole cell: red-brown, proximally bordered by slate-blue, distally with 2 irregular, darker brown triangles on it, the surroundings of which are, distally and towards the costal margin, again dusted in red-brown. Beneath brown with fine, white, torn markings and black spots at the anal angle and between the median veins. Guatemala, Guiana, Amazon.

Th. elsa Hew. (= *primno* Godm. & Salv.) (154 g) reminds us of the preceding, but it seems hitherto *elsa*. known only in the ♀. Above greenish-blue, with broad blackish-brown margins; beneath purple-brown, the proximal margin of the forewings whitish, otherwise marked as in *avoca* (154 f). Hindwings with irregular, fine, white markings and a white spot in the middle of the costal margin, distally broad whitish, dusted dark, between the median veins with a straw-coloured spot. Described from Panama.

Th. feretria Hew. (154 g) I do not know in nature, but it seems likewise to be allied to *erema* and *feretria*. to be described only according to 1 ♀. Above like *elsa*, beneath reddish-brown with a small white basal spot on each wing; forewing at the costal margin dusted in purple-brown with a white discal streak, a white post-discal macular band and light antemarginal band; hindwings at the base and in the centre purple-brown, with a very irregular white macular band in the middle and a light-brown antemarginal band; the anal lobe and a spot of the tail are black, the distal margin between is white. Habitat unknown.

Th. primnoza Dyar is perhaps the ♂ of *elsa*, above blackish-brown, in the basal two thirds of the *primnoza*. proximal margin as far as the lower cell-wall and in the disc of the hindwing light metallic blue, consequently about as in *erema* (154 f), with a most peculiar dark-grey scent-spot extending subcostally almost in half the length of the wings. Beneath dark grey, at the proximal margin whitish, hindwings only in the basal third grey, distally whitish, marked about as *elsa*, but the spot of the tail is above bordered by red. Expanse of wings: 30 mm. Mexico.

Th. hirsuta Prittw. is likewise unknown to me; it is described as a ♀, but according to the very *hirsuta*. peculiar scent-spot which seems to be equal to that of *primnoza*, it can only be a ♂; below it, at the cell-end there is yet a coniform black spot. Forewings blackish-brown, dusted in blue, two thirds of the hindwings blue with a dark costal margin; fringes white and grey speckled. Beneath light-grey, the forewings marked as in *elsa*; hindwings behind the postdiscal dusted in a sooty brown, the darkest at the costal margin; in this area there is yet a line formed of white crescents; at the anal lobe and between the median veins there is one orange spot each with a black pupil. Size and shape of *Th. quercus*. Brazil.

Th. megamede Prittw. may also belong into this group. Above azure, with brownish black margins, *megamede*. the discal spot light grey. Forewings beneath grey, at the border whitish, the broadest at the apex, in it an obsolete, grey macular band, farther proximally follows a brown, somewhat curved band, still farther some small white spots at the costal margin. Hindwings chestnut-brown mixed with white, at the costal margin a conspicuous white trapezoid-spot dusted in the middle by yellowish; in the centre the traces of a white, dentate line, the basal area quite chestnut-brown; at the anal angle a black spot being bordered above by white. Patria? This species may belong near *olbia* (154 f). Size and shape of *Th. ilicis*.

Th. zenaida Dyar, likewise unknown to me, is the best ranged here. The ♂ is above black, dusted *zenaida*. all over in blue except the margins, with an elliptic brown scent-spot filling up the distal half of the cell. The ♀ is dusted in a duller blue. Under surface dark brownish-grey, on the forewings a fine white, antemarginal moon-spot-line, proximally shaded by a broad dark-grey. Hindwing with a dark-grey shade at the base and in front of the margin; the centre is crossed by a white moon-spot-line being marked very irregularly at the cell-end; behind it another irregular moon-spot-line; marginal area whitish with a dark undulate line before it; between the median veins a black spot being red above. Expanse of wings: 29—31 mm. Mexico.

51. Lycabas-Group.

Th. lycabas Cr. (= *terentia* Hew.) (154 g). We unhesitatingly set down CRAMER's figure which *lycabas*. has hitherto not been noted to HEWITSON's species. The ♂ is above dark brown, suffused by a deep violet-blue

with a brownish-grey oval scent-spot, the ♀ is duller and more greenish blue with a marginal line being distally bordered by white, proximally by black, near the anal angle of the hindwing, which is long-stretched almost like a tail. The under surface has very characteristic markings similar to those of the *ledaea*-group. Panama, Colombia, Amazon.

52. Xami-Group.

- xami*. **Th. xami** *Reak.* (= *blenina* *Hew.*, *siva* *Edw.*) (154 g) is above brown, in the disc often more or less red-yellow; beneath pea-green on a red-brown ground with curved red-brown, distally broad white postdiscals, behind them distinct submarginal spots and orange anal spots. Vancouver, Arizona, California, Mexico.
- rhodope*. **Th. rhodope** *Godm. & Salv.* (154 g) is similar to *xami*, but the hindwings exhibit above a large orange anal spot and small black submarginal spots. Beneath, the postdiscal band is more strongly undulate, at the median veins broken, but not deeply angled. Mexico.
- loki*. **Th. loki** *Skinner* is above light brown with a tiny black lunular spot at the anal angle of the hindwing, being proximally somewhat lighter. Beneath light brown with a greenish tinge, marked as *xami*, but easily separable by a series of black submarginal spots, extending from the costal margin to the anal angle. California.
- spinetorum*. **Th. spinetorum** *Bsd.* (= *ninus* *Edw.*) (154 g, h). Above greyish-brown, towards the base tinged in a greenish bluish-grey; beneath dull reddish-brown, marked like *xami*. Colorado, California, Mexico.
- johnsoni*. **Th. johnsoni** *Skinner* is regarded as a doubtful form of the preceding by the author. Above reddish brown without the bluish-grey tinge, with a darker costal margin. Beneath the same, but the white postdiscals not so coherent, more like small spots, particularly on the hindwings, on which the 5th (beginning from the costal margin) is displaced, the last being longer than the others. Marginal line black, on both sides with white borders, at the anal angle terminating into a black spot; there are no orange anal spots. The smaller and darker ♂ exhibits the usual sexual spot. Length of forewings 14 to 15,3 mm. British Colombia; Seattle, Washington.
- castalis*. **Th. castalis** *Edw.* ♂ above yellowish-brown, both wings with a broad dark costal and distal margin. Stigma small, oval. Hindwing somewhat darkened in the disc; the distal tail quite short, the other long with a white apex; forewings below at the base and in the apical part of the margin green, the rest chestnut-brown, the shortened, interrupted discal band white. Hindwings beneath green with a white marginal line exhibiting 3 small, bluish-grey crescents at the anal angle, at the middle one of which there is on top a black spot. Right across the disc runs a sinuous chain of small white spots being anteriorly margined in brown. ♀ above chestnut-brown, the green beneath darkened. Expanse of wings 27 to 30 mm. Waco (Texas).
- ilavia*. **Th. ilavia** *Beutenm.* from Texas has a resemblance to *autolytus* (154 k), but it deviates by the under surface of both wings exhibiting only 1 transverse line. ♂ above brown with a large, red-yellow postdiscal spot of the forewing and a similar, though smaller spot in the anal part of the hindwing. Beneath rather light loam-coloured; on the forewing an interrupted, distally white-tinged transverse line. The dark line of the hindwing forms a W at the anal angle. At the anal angle itself a blue-scaled lunula, in front and behind this a small, black-marked, orange spot. ♀ similar. Expanse of wings 24 to 26 mm.
- nelsonii*. **Th. nelsonii** *Bsd.* (154 h) is above blackish-brown, in the disc bright red-yellow as *xami*, beneath duller reddish-brown, marked very much like the preceding species, but much more indistinct, the lines much finer, the small antemarginal spots smaller. — The form **exoleta** *Edw.* has beneath entirely obsolete transverse lines, f. **muirii** *Edw.* is smaller, with a darkened basal part of the hindwing beneath. California, Colorado.
- adenostomat*
tis. **Th. adenostomatis** *Edw.* (154 h) is the largest species in this group, above greyer with a fine, white marginal line at the anal angle of the hindwing; the under surface is whitish brownish-grey; the somewhat lighter marginal area is defined on the forewing by a whitish line, on the hindwing by dark submarginal moons. California.
- tacita*. **Th. tacita** *Edw.* Allied to the preceding, above light leaden-coloured, at the margin somewhat darker, as well as the discal spot and the veins. The tails of the hindwings very small and thin; near the anal angle of the hindwing an obsolete ochreous shade; fringes of both wings dull white. Under surface lighter; before the border a line of dark, small crescents; across the centre a curved chain of small oval spots. Hindwings marked indistinctly, at the anal angle a small black spot, as well as a bluish spot and hereafter a triangular, light yellowish, black-margined spot. Expanse of wings 24,5 mm. California (Mendocino Co.).
- saepium*. **Th. saepium** *Bsd.* (154 h). Above yellow red-brown, beneath dull reddish-brown, with the usual lines being distally distinctly tinged in white; at the anal angle of the hindwing 2 small black spots, between which there is bluish-grey dusting. Pacific States. — In Colorado there occurs **fulvescens** *Edw.* being still lighter yellowish-red.

Th. chalcis *Behr* (154 h) is somewhat smaller, darker brown, also beneath darker, with much duller *chalcis*. markings, without any white. California, Utah.

53. Grunus-Group (*Habrodias* *Scudd.*).

Th. grunus *Bsd.* (154 i) is above light orange-brown, in the disc still lighter, particularly the *grunus*. are often bright orange. The under surface is likewise reddish-brown with 2 rows of tiny, often indistinct antemarginal spots; between the median veins and at the anal angle, often also between both, small black spots with green-silvery pupils. — The bluish-green, short-haired and lighter striped larva lives on *Quercus chrysolepis*. California, Nevada.

54. Crysalus-Group (*Hypaurotis* *Scudd.*).

Th. crysalus *Edw.* (154 i) is a large species differing greatly from all the others we know. Above *crysalus*. blackish-brown, in the basal half of the forewing and subapically, as well as in the disc of the hindwing, lilac, towards the anal angle of both wings spottend in orange. Beneath greyish-brown with darker discal streaks bordered on both sides by white, and with dark, distally white-tinged, postdiscal stripes on both wings, on the hindwing also with a proximally whitish additional basal streak; blackish submarginal lunae are proximally bordered by white on both wings, on the forewings analwards distally by orange-yellow; on the hindwing there is behind them towards the anal angle an increasing bluish-silvery dusting, between the median veins and at the anal lobe orange-red, black-pupilled spots being often connected by a bridge. California, Arizona, Utah, and South Colorado. — The form *citima* *Edw.* has above no orange spots and is beneath more grey-coloured. *citima*.

55. Calanus-Group.

Th. calanus *Hbn.* (= *falacer* *Godt.*, *inorata* *Grote & Rob.*) (154 i) is above plainly dark-brown with *calanus*. an oblong-oval — twice as long as broad — lighter scent-spot in the distal half of the cell; beneath nearly just as dark brown with postdiscal and submarginal rows of darker spots, distally bordered by fine bluish-white lines and similar discal spots. Between the median veins and above them, as well as at the anal angle, there are dark-red spots, the space between them is densely strewn with bluish-white. — f. *lorata* *Grote & Rob.* is *lorata*. somewhat smaller, beneath lighter with less distinct small spots. — The larva lives on oak-trees. In the Atlantic States and the Rocky Mountains it is common.

Th. heathii *Fletch.*, described only according to 1 ♀, is unknown to me. Above like *calanus*, beneath *heathii*. fawn-coloured with pearl-grey postdiscal spots, 4 of which on the forewing are oval, bordered on both sides by a darker band, 5 of which on the hindwing are more four-cornered, bordered on both sides by a black band; marginal spots as in *calanus*, towards the anal angle likewise scarlet, between them a plainly white, not blue spot. Expanse of wings 26 mm. Manitoba (Long River).

Th. ontario *Edw.* resembles *melinus* (159 g); expanse of wings 26 mm. On both surfaces brown, the *ontario*. forewing with a large, smooth, oval scent-spot, the fringes dark, in some places white; hindwings before the anal angle with some small, reddish-yellow scales. Beneath lighter brown, the small spots of the discal row touch each other on the forewing except 2; a distal row of more obsolete spots. On the hindwing the spots of the distal row are separated, the row straight, forming a W in the anal part. In front of the border black and bluish bordered internerval spots the 4 apical ones of which are small, the 5 th and 6 th marked in orange-red. Near the base of the tail a heap of blue scales; in the anal region a red spot marked in black and white. Based upon 1 ♂ from Ontario (July).

Th. liparops *Bsd.* (= *strigosa* *Harr.*) (154 i) is above brown like the others, beneath maybe some- *liparops*. what greyer, marked just the same, but by the widening of the dark spots the fine white stripes are much more apart from each other and often very indistinct. — The larva lives polyphagously on the most different foliage-trees, on Rosaceae and Ericaceae. Distributed in the North Atlantic States and the Rocky Mountains, but nowhere common.

Th. edwardsii *Snds.* (= *fabricii* *Ky.*) (154 i) vice versa differs beneath from *calanus* by a considerable *edwardsii*. diminution of the small dark spots which are mostly all round bordered by white, so that small eyespot-rows are produced; above there is hardly any difference, perhaps the brown tinge is somewhat lighter, the scent-spot is thrice as long as broad, appearing therefore narrower. — The larva lives on oaks. In the Northern States, mostly common.

Th. wittfeldi *Edw.* (154 k) is larger than the preceding, above differing by the darker colour and a *wittfeldi*. large orange spot between the median veins and a fine bluish-white, proximally black, marginal line analwards. Beneath the white lines are more continuous, placed nearer to the border, the red anal spots larger and more intense, the space between them less blue. Florida.

- autolyceus*. **Th. autolyceus** Edw. (154 k) resembles *melinus* (159 g) above, but the orange spots are much more extensive. Beneath brown, similar to the preceding species, with dark, distally white-bordered postdiscals and black submarginal crescents which are analwards distally spotted in red. Texas, Missouri and Kansas.
- alcestitis*. **Th. alcestitis** Edw. (154 k) is above dull-brown with the usual oval scent-spot in the ♂, beneath very much like *autolyceus* with whitish discal streaks and dusted greenish-blue in the submarginal submedian area of the hindwing. Texas and Arizona.
- oslari*. **Th. oslari** Dyar is closely allied to *alcestitis*, but smaller, the upper surface greyer brown, beneath ashy-grey instead of brown, and the red markings outside the distal band are less developed. Expanse of wings 16 mm. Tucson, Arizona.
- acadica*. **Th. acadica** Edw. (= *souhegan* Whitney) (154 k). The upper surface is brownish slate-grey, towards the anal angle with small orange spots on the hindwings and an oval scent-spot. Beneath differing by black cell-end-streaks and by the postmedian and submarginal macular rows being replaced by smaller black, white-ringed spots; analwards there are small antemarginal red spots, and between the spot of the tail and the anal spot there is greenish-blue dusting. — The larva lives on willows. Northern States, Nevada, Arizona.
- californica*. **Th. californica** Edw. (= *borus* Bsd., *cygnus* Edw.) (154 k) differs from *acadica* above by its light-brown colour, also on the forewings at the proximal angle with 2 small orange spots; beneath grey, with a reddish-brown tinge, near the apex of the forewing with small reddish-yellow marginal lunulae. In the ♀ the under surface is more dirty white. California.
- ityis*. **Th. itys** Edw. (154 k) is above brown, particularly in the ♀ with a light reddish-yellow brightening towards the proximal angle. Beneath light greyish-brown, the submarginal row of spots quite obsolete on the forewings, on the hindwings there is here a complete row of black dots; at the anal angle a velvety-black spot, above it some small orange scales; between this and the orange spot of the tail a bluish spot margined in black; the postdiscals consist of minute black, white-ringed spots. Expanse of wings: 32 mm. Prescott, Arizona.
- auretorum*. **Th. auretorum** Bsd. Above brown with 1 or 2 small orange spots towards the anal angle on the hindwing, beneath likewise brown, the row of eye-spots undulate, not very distinct and placed near the border, at the anal angle with 2 tiny reddish-yellow lunulae, the anal lobe bordered by black. California.
- dryope*. **Th. dryope** Edw. (154 k) is above quite light-brown, towards the base slate-grey, at the anal angle with 2 small yellowish-red spots, the one below the median veins being pupilled in black. The under surface is whitish-grey with the usual rows of eye-spots and a small orange spot between the tails. California, Nevada, Utah.
- sylvinus*. **Th. sylvinus** Bsd. is above darker blackish-brown, otherwise very similar to the preceding. Beneath light ashy-grey with a dark cell-streak and 2 curved rows of eye-spots, the hindwings between the tails with small orange, black-pupilled spots and towards the proximal margin from them a bluish-grey spot. Common in California.
- putnami*. **Th. putnami** Edw. 30 mm. Above fawn-coloured with white fringes. Hindwings with 4 indistinct, dark small crescents and an anal spot covered with golden-yellow. Tails black, with white margins and a broad white apex. Under surface greyish-white. Forewing with a discal luna and 6 submedian, oval spots, each with a white ring; near the anal angle 4 black streaks. Hindwing with a discal luna and a row of 7 spots. Marginal markings obsolete, anal spot orange, marked in black, the 2nd and 3rd with interspersed small blue scales, the 4th black, above orange. Utah, Colorado.
- spadix*. **Th. spadix** Edw. is allied to the preceding and just as large. Above mouse-coloured with a large, chestnut-brown shade on the forewing. The band-marking beneath very much blurred, on the hindwing irregularly broken; the anal spots are dirty brown, there is not the least to be noticed of orange or blue. Expanse of wings 24.5 mm. South Carolina.
- tetra*. **Th. tetra** Behr. Above light-brown, beneath lighter; both wings with a joint, more indistinctly tortuous median row of whitish lunulae; on the hindwings small black, antemarginal crescents, anteriorly with some whitish scales. Tail-spot orange, between it and the anal angle a blue spot. Expanse of wings: 30 mm. California.

56. Behrii-Group (*Callipsyche* Scudd.).

- behrii*. **Th. behrii** Edw. (= *kali* Streck.) (154 k) somewhat resembles the subgenus *Erora* in the scheme of markings beneath. Above red-yellowish brown with a broad blackish-brown costal and distal margin. Beneath yellowish-grey with a curved, on the hindwings strongly broken, postdiscal band of black, distally white, small spots and small submarginal lunular spots, between the median veins of the hindwings with a more intense black spot behind. Pacific States, Rocky Mountains.

57. Gargara-Group.

Th. gargara Hew. (155 a) is a smaller species which is difficult to range. The ♀ is blackish-brown *gargara*, above, towards the base blue; beneath brownish-grey, the indistinct postdiscal band darker brown, the space behind more red-brown; on the hindwing there is behind the dentate, dark-brown postdiscal a broad, lilac-white band; the two small anal spots are bordered upwards by orange, then by yellow. Amazon.

58. Ocrisia-Group.

Th. ocrisia Hew. (= *peruviana* Ersch.) (152 b) is above blackish-brown, on the forewing towards *ocrisia*, the proximal margin with a slight steel-blue reflection and near the base a large, round, brown scent-spot embedded in a slate-grey circumscription like an eye. The hindwing is in a very variable extension strewn with metallic-blue, mostly only in the inner-marginal half; there are also some blue antemarginal crescentiform spots. — In case the blue disappears altogether, we have **zora** Hew. before us. — Beneath likewise blackish-brown, forewing at the proximal margin whitish-grey, at the apex yellowish-brown, marbled with very irregular and indistinct markings, between the median veins a small orange spot. Very widely distributed from Mexico through the whole of Central America as far as Peru, Bolivia, the Amazon, and Paraguay.

Th. ocrida Hew. (152 a) is above similar, the ♂ is more blue, also on the forewings, the scent-spot *ocrida*, spot proximally dark-brown, distally black; the ♀ unicolorously brown. Beneath very easily recognizable by the yellow anal angle of the hindwing, in the ♀ the whole distal margin is broad yellow. Colombia, Amazon.

Th. arpoxida sp. nov. (155 a) connects *ocrida* with *arpoxais*; shape and colouring above as in the *arpoxida*, former, cyanean-blue with a broad black apex and costal margin, also the scent-spot is the same. Beneath dark-brown, lighter marbled, like *ocrisia*, but with the silvery-blue linear markings of *arpoxais*, also parallel to the base of the costal margin there is one like it. Described according to 1 ♂ from the Rio Songo (Bolivia) from the Coll. FASSL.

59. Thales-Group.

Th. thales F. (= *thrasyllus* Hbn.) (155 a) is closely connected with the preceding group and has *thales*, the same shape of the wings. Above black, strewn with blue in a very variable extension, particularly in the shape of spots before the distal margin of the hindwings, often also at the anal angle of the forewing. The small, hardly visible scent-spot is dark-brown. Beneath purple-brown with 5 bluish-white costal-marginal spots of the forewings and fine blue linear markings, at the anal angle broadly strewn with greenish-golden. The ♀ is above unicolorously brown. Distributed from Nicaragua to South Brazil and common. — **thalesa** Hew. is *thalesa*, presumably only an insignificant form in which the costal spots beneath are more intense, and the last is situate closer to the apex.

Th. arpoxais Godm. & Salv. (= *clepsydra* Drc.) (155 a) really belongs into a group of its own, *arpoxais*, but as it greatly resembles the preceding beneath, we range it here. Above magnificently cyaneous with a broadly black apex and a large black spot filling up the distal half of the cell, the subcostal above it set with a silvery-grey scent-scale-stripe. Beneath purple-brown, at the apex of the forewing and at the anal angle of the hindwing lighter brownish with blue markings and some green dusting at the anal angle. Panama to Bolivia (Rio Songo).

60. Besidia-Group.

Th. besidia Hew. (152 h) is apparently a very rare, smaller species; the ♂ above lustrous blue, *besidia*, with a broadly black apex and a rather large, pear-shaped, dark scent-spot at the cell-end and behind it; the ♀ is above duller and lighter blue with an extensive black margin and apex. Beneath reddish-brown with a lilac reflection; there is a characteristic median band of the hindwing, being proximally broadly tinged in red (in the figure unfortunately greenish). Brazil, Colombia, Bolivia (Rio Songo, FASSL).

Th. torris Drc. (155 a) closely allied to the preceding, above more indigo-blue, darker, beneath lighter *torris*, greyish-brown without the purple tinge, both wings at the distal margins broadly whitish, the transverse bands proximally not shaded by red, but by sepia-brown; the orange spot between the tails is absent. Rio Grande.

Th. bagrada Hew. (152 k) differs from *besidia* by its duller lilac-blue colour being more confined; *bagrada*, below the brownish-grey part of the scent-spot it another black one on the base of the median veins. Beneath coloured like *besidia*; the proximally red median band of the hindwing begins at the costal margin with an isolated spot dislodged outwards and being bordered by black and white on both sides. The ♀ is above and beneath lighter. Amazon.

Th. obelus Drc. (152 k) approximates *bagrada*, is above more lustrous dark-blue with a smaller *obelus*, round single scent-spot at the cell-end, beneath darker red-brown, the median band of the hindwing more coherent and more sinuous. The ♀ is above brown, beneath somewhat paler. Brazil.

- litteratus*. **Th. litteratus** Drc. (155 a) has above quite brown forewings with a small, light, oval scent-spot; hindwings brown, in the larger proximal half metallic blue, with a red anal spot. The under surface is lighter, the markings as in *besidia*, but narrower and distally bordered by a pure white. The ♀ is on the hindwings dull greyish-blue with indistinct, small, brown marginal spots. Paraguay.
- nugar*. **Th. nugar** Schs. (155 b) is very closely allied to the preceding. Forewings brown with a small light scent-spot, hindwing in the larger proximal half metallic light lilac-blue. Beneath brownish-grey, the proximal line orange-brownish, distally white, between the radial veins dislodged outwards, the costal spot, however, only slightly so. Described from Mexico (Jalapa), but it is before me also from Colombia (Rio Aguaca Valley) and from the Songo (Bolivia) and, therefore, apparently widely distributed.
- xorema*. **Th. xorema** Schs. is likewise similar, above like *obelus* (152 k), beneath lighter; the transverse bands are dark-brown, not red, outside broadly whitish; the ♀ is above dark-brown, towards the base suffused with blue. Expanse of wings: 20 mm. Brazil.
- cauter*. **Th. cauter** Drc. (152 i). Above likewise very much like *obelus* (152 k), the blue more indigo-coloured, the distal margin of the hindwing broader black and with a very large, red anal spot. Beneath more rusty-brown, the markings very broadly tinged in red, the postdiscal band of the forewing, beginning from the lower radial vein, dislodged inwards, that of the hindwing on both sides bordered by black and then by white, the whole anal area extensively red. The ♀ is above brown with a large, orange anal spot. British Guiana, Brazil.
- lanckena*. **Th. lanckena** Schs. is allied to *bagrada* (152 k). Above unicolorously blackish-grey with a red anal spot of the hindwings. Beneath light-brown with red, distally black-, then white-bordered lines, on the hindwing at the costal margin, then between the radial veins distally expanded, otherwise like the allies. Expanse of wings: 28 mm. Peru.

61. Tiasa-Group.

- tiasa*. **Th. tiasa** Hew. (155 b). ♂ above deep purple-blue with comparatively narrow black margins and a small double scent-spot, inside black, outside greyish-brown; at the anal angle of the hindwing a red spot. Beneath brown with white lines, on the hindwings contiguous; the extensive red anal spot connected with the spot between the median veins by a red band. Amazon.
- ortalus*. **Th. ortalus** Godm. & Salv. (155 b) is very closely allied to the preceding; the ♂ is above less purple-blue; on the under surface of the hindwing the white lines diverge more from each other towards the costal margin. The ♀ is above plainly brownish-grey with a greenish reflection at the base of the wings. From Mexico.
- praxis*. **Th. praxis** Godm. & Salv. (155 b) differs from *ortalus* by the much broader blackish-brown apex of the forewing. The anal lobe is beneath black, upwards but quite slightly red, towards the proximal margin strewn with white; between it and the small red spot of the tail lies a blackish spot in the brown ground. The ♀ is above dull brownish-grey, towards the base with a slight, bluish-grey tinge. Panama to Brazil (Sta. Catharina).

62. Erix-Group.

- erix*. **Th. erix** Cr. (= *tyrrhenus* Hbn., *erissus* Hbst.) (155 b). Above magnificently ultramarine-blue with a moderately broad, black margin; the discoidal cell is very short, therefore the position of the small black scent-spot in the upper corner near the base, above at its outside it is touched by a tiny brown scent-spot at the base of the subcostal veins; at the anal angle a minute red-brown spot. Beneath coffee-brown, on the forewing with 2 antemarginal lines, the inner one of which is distally bordered by white. Hindwings darker with a bluish-white, proximally dark-tinged, postdiscal W-line and an antemarginal row of dark spots, bordered on both sides by a lighter colour and being interrupted between the median veins by a red, black-pupilled spot. In the anal lobe a red spot bordered above by black and white. Amazon.
- timoclea*. **Th. timoclea** Hew. (155 c) is considerably larger, darker indigo-blue, with a much larger, oval, blackish-brown scent-spot surrounded by slate-green scent-scales, with a broader black apex. Beneath similar to *erix*, the fine lines formed of silvery-blue scales sprinkled on it; at the base of the costal margin is a silvery-blue dot. From Ecuador.
- cetra*. **Th. cetra** sp. nov. (155 c) resembles the preceding above, but it has longer hindwings, a duller steel-blue colour and a larger, double scent-spot, the proximal half being red-brown, the distal half, being separated by the blue transverse vein, greyish-brown. Beneath very similar; on the forewings the curved proximal line is likewise bluish-white, on the hindwings the blue basal dot is absent, the postdiscal line is clearer, not composed of dispersed scales. According to a pure ♂ from Muzo (Colombia) from the Coll. FASSL.

Th. ismarus Cr. (155 c) of which we reproduce a copy of CRAMERS figure, seems to me to be closely *ismarus*, allied to *timoclea*. The same seems to me to be the case with

Th. phalantus Cr., perhaps both are the sexes of one species; at any rate neither of them has been *phalantus*, identified up to this day, for which reason we confine ourselves to this short remark; both originate from Surinam.

63. *Spurina*-Group.

Th. spurina Hew. (= *stagira* Hew., *volana* Hew., *timaea* Hew., *lydia* Ky.) (152 h, i) is above steel- *spurina*, or slate-bluish grey, with a dull greasy lustre, narrow black margins and a double scent-spot, the upper distal portion brownish-grey, the lower red-brown. Fringes blackish-grey, at the anal angle white with a black marginal line before it. The ♀ is dull greyish-brown, towards the base bluish-grey, towards the anal angle with blackish marginal spots and a reddish or bluish spot in the anal lobe. Beneath brown, the ♀ lighter. On the forewings a curved or straight row of lunular spots, brown, distally mostly whitish; on the hindwings a strongly curved, postdiscal similar one, and an antemarginal, very dull one, being lighter tinged on both sides; between the median veins a red crescent with a small, black dot; in the anal lobe a black spot with mostly some red above between it light-blue dusting. — The insignificant form **erenea** Hew. has a still narrower black distal margin *erenea*, and on the hindwings beneath a less curved median band. From Panama to Colombia and the Amazon.

Th. endera Hew. (= *thestia* Hew.) (155 c) is above greasy-lustrous greenish-blue, with a broadly *endera*, blackish-brown apex and margins. Scent-spot large, oval, brown; ♀ duller greyish-brown, towards the base bluish-grey. Beneath more intensely brown than the preceding with more distinct submarginal lines on both wings and very much larger red spots. Amazon.

Th. genena Hew. (155 c) looks almost the same above, but the scent-spot is smaller; on the hindwings *genena*, beneath, the postdiscal band makes an almost U-shaped curve, whereas in *endera* it runs almost rectilinearly to the proximal margin. Amazon.

Th. buris Drc. (155 d) differs from the preceding by its almost purely green upper surface and double *buris*, scent-spot: in the cell black, behind it brown; beneath not different. The ♀ is above brown with an orange anal spot, beneath paler than the ♂ with more red at the anal angle. Amazon.

Th. illex Schs. seems to approximate the preceding and has the same double scent-spot; above metallic *illex*, blue with a broadly black apex and a narrowly black distal margin and a red anal spot. Beneath brown with the same markings as *buris*, only somewhat more bluish instead of white. Expanse of wings: 33 mm. Colombia.

Th. caltha Drc. (154 d) is above dark-brown, towards the base suffused by purple-blue; almost *caltha*, the whole cell is occupied by a slightly conspicuous, purse-shaped scent-spot with a longitudinal opening from which whitish scent-scales spring forth. Beneath like *spurina* (152 h, i), but with more red at the anal angle. The ♀ is above quite brown with an orange anal spot. Amazon.

Th. emessa Hew. (155 d) resembles *endera* (155 c) above, but it is brighter bluish-green, the margins *emessa*, are deeper black and more sharply defined, so that the dark-brown scent-spot becomes more prominent. The ♀♀ are in all these species above equally coloured, dull brownish-grey, towards the base tinged bluish-grey. The under surface is lighter than in the others, orange-grey with the usual, little differing lines and small red anal spots. Amazon.

Th. eliatha Hew. (155 d) is above more extensively greenish-blue than *genena* (155 e) and possesses *eliatha*, a large, double scent-spot, the proximal half of which is orange-brown, the distal half greyish-brown; beneath likewise similar to the said species, but on the hindwing the lines are not so close together and the distal one consists of conical or triangular, whitish spots being distally bordered by brown. Only between the tails there is a small red spot, the anal spot is black, between both there is bluish-white dusting. Brazil.

Th. ericusa Hew. (= *voconia* Hew.) (152 g, h) is the most closely allied to the larger *spurina* (152 h) *ericusa*, and has the same greasy-lustrous, steel-grey colour, but only a small, brownish-grey scent-spot behind the cell, the proximal part has disappeared except some traces of it. Beneath somewhat lighter, with a lilac tinge, between the anal- and tail-spots dusted more bluishly, the marking the same. Colombia, Bolivia, Brazil.

Th. sycena Hew. (155 d) presumably also belongs to this group, although the ♂ is without the scent- *sycena*, spot. Above metallic blue with a black apex and a narrow distal margin. Under surface brownish-grey with the same markings; on the forewings the row of spots is almost straight, on the hindwings more strongly broken, than in the other species. Brazil.

- legythia*. **Th. legythia** Hew. (152 i) is so closely allied to *emessa* (155 d) that it may coincide with it. Above greenish-blue with a black costal margin and apex and a black scent-spot. Beneath on the hindwings the post-discal band runs somewhat differently towards the costal margin, otherwise everything is alike. Nicaragua.
- gargophia*. **Th. gargophia** Hew. (152 i) resembles the preceding, but it is above not so green, but of a purer blue, and it has a double scent-spot, proximally black, distally brownish-grey. Beneath alike. Brazil (Espiritu Santo).

64. *Sophocles*-Group.

- sophocles*. **Th. sophocles** F. (♀ = *basalides* Hbn., *wilhelmina* Ky., *sphinx* Godt., ♀ *dindymus* Ww., *virginia* Stgr. i. l.) (155 d) initiates a very characteristic group. The ♂ is above radiantly azure-blue, on the forewings, however, only in a parallel-bordered stripe between the proximal margin and the lower median vein, the rest is blackish-brown; three fourths of the cell are filled up by the deep-brown scent-spot. The under surface is whitish-grey, in the basal inner-marginal part of the forewing brownish-grey; on the forewings 2 lines composed of brownish crescentiform streaks, the proximal one very constant and characteristic by the luna between the upper radial veins receding towards the base; hindwing in the distal part almost white with a tiny orange spot between the median veins; the postdiscal strongly broken; there is mostly a third line in the basal part. Brazil.
- sospes*. **Th. sospes** sp. nov. (155 e) is very similar, above slightly duller blue, the just as broadly black apical part exhibits in the disc an indigo-blue lustre; in the upper distal cell-corner is the very small, oval, deep brown scent-spot; beneath very light brownish, of the lines only the postdiscal one is visible, being, however, also very slightly marked; the orange anal spots are both present, though small and dull. According to 1 ♂ from Colombia in my collection.
- tephraeus*. **Th. tephraeus** Hbn. (= *faventia* Hew.) (155 e) is above similar to *sophocles*, but the apex is less extensively black, so that the proximally brown, distally black scent-spot is entirely surrounded by blue. Beneath the ground-colour is light ashy-grey, in the place of the scent-spot brownish, the distal part of the hindwing very much dusted in white, the lines distally bordered by a clear white, brought nearer to the border, mostly with a fine white discal streak. The ♀ resembles the other species, it is of a duller blue, distally broader brownish-grey. Distributed from Mexico to the Amazon and everywhere common.
- leucophaeus*. **Th. leucophaeus** Hbn. (= *halala* Hew., *parvinotus* Kaye) (151 c ♀, 155 e ♂) differs above by only quite narrowly black distal margins and a smaller, more distinctly double scent-spot. Beneath grey as *tephraeus*, but the markings more like in *sophocles*, the distal margin of the hindwings mixed with white, the postdiscal line of the forewings almost straight. Brazil, Venezuela, Trinidad.
- volupia*. **Th. volupia** Hew. is above not to be distinguished from the preceding, beneath more monotonously grey, the anal lobe black, without a red border. Guatemala, Nicaragua.
- purpurea*. **Th. purpurea** Drc. (155 f). Above darker than *leucophaeus* and with a broader, black distal margin, the scent-spot still smaller and distinctly bipartite. Under surface pearl-grey without the white mixture at the distal margin, forewings quite unmarked; the postdiscal line on the hindwing separated more into single spots. Brazil (Espiritu Santo).
- hostis*. **Th. hostis** Schs. is likewise closely allied, but it has above a broader black apex and costal margin. The small double scent-spot is proximally brown, distally grey, both parts surrounded by blue, touching the black costal margin above. Beneath more brownish-grey, marked as in *leucophaeus* (154 e), the red spot of the tail much larger. Expanse of wings: 28 mm. Brazil (Novo-Friburgo).

65. *Doryasa*-Group.

- doryasa*. **Th. doryasa** Hew. (155 e) is above magnificently lustrous ultramarine blue with a sharply defined, velvety-black apex and a narrow distal margin. The larger, black part of the scent-spot is situated in the cell, the smaller, brownish-grey part behind it. The ♀ is dull blackish-brownish, on the hindwings suffused by a dark steel-blue. The under surface is brown with a fine black, distally white postdiscal line forming a W at the proximal margin. Marginal line quite obsolete, 2 red anal spots, between them bluish dusting; marginal line black, proximally intensely white. Colombia, Amazon. — **epidius** Godm. & Salv. (155 f) is slightly different, but easily separable by the almost vanished, red spot on the tail of the hindwing beneath. Panama to Colombia.
- nota*. **Th. nota** Drc. (155 f). Above not to be distinguished from the preceding, beneath more light straw-coloured with fainter and less undulate transverse lines; the antemarginal rows of moon-spots are absent altogether, the red spots have almost disappeared. Colombia (San Sebastian).
- leos*. **Th. leos** Schs. (155 f) has above a much larger black scent-spot in the cell-end, otherwise very similar to *doryasa* (155 e). Beneath darker brown and easily recognizable by the peculiarly curved postdiscal line. Costa Rica.

Th. nivepunctata Drc. (155 f). We add here 2 very different species being otherwise not related to *nivepunctata*. any other group. The species before us has above the greasy-lustrous indigo-blue of *spurina* (152 h, i), but a much broader dark apex and at the cell-end a pear-shaped, brownish scent-spot. Beneath not to be mistaken for any other species by the chocolate-coloured, white-dotted under surface. The ♀ is above duller coloured, otherwise the same. From British Guiana and Surinam.

Th. porphyreticus Drc. (155 f). Above about as *tephraeus*, but with a broader black margin and a smaller dark-brown scent-spot. Beneath brown with a violet reflection, very characteristic by the two large, white, costal-marginal spots of the hindwing. Peru (Rio Napo).

66. Syncellus-Group.

Th. syncellus Cr. (151 i, k). ♂ above magnificently lustrous blue with a moderately broad black margin and a black scent-spot behind the cell, bordered in the cell by a smaller, red-brown spot being circumscribed like an eye by slate-blue. Beneath greyish-black with a darker transverse line and silvery green dusting at the anal angle in the shape of 2 short transverse lines, the proximal one forming a W; abdomen beneath yellowish-white. The ♀ is above darker steel-blue, beneath more yellowish-brown. Everywhere extremely common from Mexico to the Amazon; northern specimens generally have a narrower black margin. — From West Mexico (Guerrero) I received a number of specimens of a smaller, much lighter form with an almost extinct scent-spot and beneath light yellowish-grey ground-colour, which I denominate **deserta** form. nov. (151 k); — *deserta*. **eribaea** Hew. (151 k) is a form with the postdiscal on the under surface being distally broadly dusted by light-blue, from the Amazon. — *bitias* Cr. is most probably a synonym of *syncellus*.

67. Hebraeus-Group.

Th. hebraeus Hew. (151 k) entirely resembles above our figure of *deserta* (151 k), but it is of a more violet colour, the scent-spot is the same, smaller than in *syncellus*, the extensive black part behind the cell is absent. Beneath brownish with undulate, black streak-markings which are well to be seen from the figure. Bahia.

Th. cimelum Gosse (151 k) is extremely similar and above not to be distinguished, the under surface, however, is much more clouded in dark and more indistinctly, more blurredly marked. Brazil to Paraguay.

68. Pelion-Group.

Th. pelion Cr. (= *simplex* Walch., ♂ *thallus* Cr., *aeolus* F.) (148 e). Above blue with a narrowly black margin and a large, black scent-spot. Beneath blackish-grey with a slight purple tinge and a broad, white band of the hindwing parted by the veins; between the median veins an antemarginal, carmine spot, at the anal angle some silvery-blue scaling. Brazil, Trinidad, Ecuador.

Th. paphiagon Fldr. (148 f). ♂ above radiantly greenish-blue with a large, black scent-spot at the cell-end and some black dusting behind it. Distal margin narrowly black. On the upper surface of the hindwing there is a pencil of black hair on the submedian. The ♀ is more green with a much broader, blackish-brown margin. Beneath brownish-grey with a whitish inner-marginal area and black veins, a small, white, costal-marginal spot of the forewing and a yellow apical spot of the hindwing, in front of the anal margin of which there are 2 red spots. Colombia, Venezuela, Peru.

Th. ochus Godm. & Salv. (148 f) resembles the preceding above, darker blue and with a much larger black discal spot below the scent-spot and a black hair-pencil at the submedian. Beneath likewise similar, the light costal marginal spot of the forewing is larger and triangular, the apical spot of the hindwing not yellow but whitish, extending subcostally as far as the base. Before the margin only one red spot, a smaller one in the anal lobe. Mexico, Guatemala, Panama, Costa Rica.

Th. boreas Fldr. (148 f) likewise belongs here; it is smaller, above similar to *paphiagon*, beneath much more variegated by more abundant yellow spotting, a red costal margin of the hindwing, and more extensively red spots between the median veins and above them. Colombia, Amazon.

69. Coelebs-Group.

Th. coelebs H.-Schöff. (= *fidena* Hew.) (155 f, g) is above lustrous steel-blue, more greenish than *spurina* (152 h, i), distally very broad blackish-brown with long hair above in the submedian space of the hindwing and a hair-pencil at the base of the subcostal, without a scent-spot. The ♀ is above duller greyish-blue. Beneath brown, the postdiscal line darker, on the hindwings distally white, beginning in the middle of the costal margin; anal lobe black, above bordered by white, between it and the large red spot of the tail blue dusting. Cuba, Hayti.

- panchaea*. **Th. panchaea** Hew. (= *scoteia* Hew.) (155 g) is above rather similar, in the ♂ bluer, the hindwings of a rounder shape. Beneath the transverse lines are fine, nearer to the margin and parallel to it, the red spot on the tail smaller. Amazon. Minas Geraes.
- pion*. **Th. pion** Godm. & Salv. (155 g) looks above like the preceding and has the same subcostal hair-pencil and the submedian hairing on the hindwings; beneath it is duller and more indistinctly marked, the small red spot quite insignificant. Perhaps it is a form of *panchaea* and its northern representative. Distributed from Mexico to Panama.
- oppia*. **Th. oppia** Godm. & Salv. (155 g) is above much more extensively blue and, on the hindwings, it has a distinct, small, red anal spot. Above the subcostal hair-pencil of the hindwing is a black scent-spot. Beneath it is much more abundantly marked in white, also before the margin. Described from Mexico.
- piplea*. **Th. piplea** Godm. & Salv. (= *subobscura* Lathy). Allied to *pion* (155 g); the ♂ with the small hair-spot on the upper surface of the hindwing near the base of the subcostal vein. But beneath the wings are of a more intense colour than in *pion*. The dark-red anal spot of the hindwing is much larger, the two transverse macular stripes nearer to each other. West Indies: St. Vincent (Grenada).
- martialis*. **Th. martialis** H.-Schüff. (155 g) on the whole resembles *coelebs* above, but it is of a duller sky-blue and immediately distinguishable by the large, indistinctly defined, discal spot. Beneath the markings are likewise very similarly arranged, but instead of the rows of moonspots there are rather broad white lines. Florida, Cuba, Jamaica.

70. Strephon-Group.

- strephon*. **Th. strephon** F. (= *sichaeus* Cr.) (151 d). Upper surface magnificently cornflower-blue with a very broad black apex with indistinctly visible scent-scales; the anal angle of the hindwing above bordered by white, in the black lobe a small red spot. Beneath brownish-grey, the proximal margin of the forewing whitish with a large, oval, brown scent-spot below the median, covered by the convex, bulging margin of the hindwing. The postdiscal lines are white, running on the forewing from the middle of the costal margin straight to the lower median vein, and from here as far as the proximal margin in the shape of a W; submarginally placed is a row of brownish moon-spots, bordered on both sides by white, between the median veins and at the anal angle interrupted by red spots. Amazon.
- cyllarus*. **Th. cyllarus** Cr. (= *strephon* Godt. nec F., *cyllarissus* Hbst.) (151 f) is above the same, only somewhat more greenish, and the angle between the median veins on the forewing is still blue, in *strephon* already situate in the apical black. Beneath much lighter, the markings duller and finer, parallel to the margin. The ♀, as almost all of this group, is above much duller and the blue more confined, the shape of the wings rounder and broader. Brazil to Peru. — **Th. deliciae** Drc. (151 i) seems to be based only upon an aberrative specimen in which all the black markings beneath are absent; taken in North Brazil.
- porphyritis*. **Th. porphyritis** Drc. (151 h) does not differ from *strephon* above and it is just as dark beneath, but the marking is parallel to the border as in *cyllarus*, the white colour very prominent, the scent-spot much smaller, nut-brown and nearer to the base; the disc exhibits a silky lustre. Brazil (Tapajoz and Para).
- perola*. **Th. perola** Hew. (151 g, h). Above like *cyllarus*, distinguished on the hindwing by the broad blackish-brown costal margin shining as if polished. Beneath the white markings are strongly developed, the postdiscal line more strongly and irregularly broken, the blackish-brown scent-spot extends as far as the median. Amazon, Bolivia.
- tyriam*. **Th. tyriam** Drc. (151 h) differs from the preceding above by the reduced blue of the forewings, which does not reach the anal angle, but is cut off by the broadly black distal margin; the costal margin of the hindwing is likewise polished. The under surface is lighter, the scent-spot smaller, lighter straw-coloured than the ground. Brazil (Pará), Bolivia.
- trebonia*. **Th. trebonia** Hew. (151 e) differs from the preceding by the large scent-spot in the distal half of the cell; the ground-colour is a lighter, greener blue. Beneath as in *perola*. Ecuador.
- uterkudante*. **Th. uterkudante** Drc. (151 e) has above the blue of *strephon* (151 d) and no scent-spot; beneath it differs from the preceding by a straw-coloured scent-spot and much broader black and white transverse lines, the proximal one of which begins at the costal margin with a large triangular spot. Colombia.
- ostrinus*. **Th. ostrinus** Drc. (151 f). Above like *strephon*, but without the red spot in the anal angle of the hindwing. The ground-colour beneath is of a decidedly greenish tinge and the scent-spot is absent altogether Cayenne.
- Th. phoster** Drc. (151 f) does not differ from *cyllarus* above. The ground-colour beneath is much darker and lustrous; the scent-spot is much larger, but it does not contrast in the colour; the postdiscal band is very prominent; the red spots are very strongly developed. Surinam, Colombia (Muzo).

Th. foyi Schs. resembles the preceding above, in the anal lobe a small orange spot. Beneath light *foyi*, greyish-brown, without a scent-spot, the markings as in *phoster* (151 f), duller, but on the forewing the submarginal line is absent, the proximal one extends only as far as the lower median vein. Described from Peru.

Th. purpurantes Drc. (151 g) is above greener blue than *foyi* and has no orange spot in the anal lobe; *purpurantes*, beneath the black and white postdiscal line is more sharply broken angularly and more prominent. The scent-spot is of a silky-lustrous straw-colour, in the centre darker. Peru.

Th. acameda Hew. (= *paulina* Stgr. i. l.) (151 f) resembles *cyllarus* above, but it has a green-reflecting *acameda*, polished costal margin of the hindwing, the costal angle itself being blue. On the under surface the basal half at the hindwings, particularly towards the costal margin, is darker brown, the scent-spot is quite light cement-coloured; the strongly broken lines are well reproduced in the figure. Amazon, Colombia, Peru.

Th. elika Hew. (151 g) has above a decidedly lighter and greener blue with a more narrowly black *elika*, distal part. The under surface is much lighter whitish-grey, the lines finer, towards the costal margin on the hindwing more divergent, the red marginal spots smaller and duller, the costal margin of the hindwing is less convex, the scent-spot hardly contrasts with the ground. Brazil.

Th. ambrax Ww. (151 f) has a still much narrower black apex and distal margin, and is immediately *ambrax*, recognizable by the large, oval, red-brown scent-spot at the upper cell-end. Beneath light ashy-grey, the large scent-spot clay-coloured, the lines as in *acameda* (151 f). Nicaragua, Panama, Colombia, Brazil.

Th. adela Stgr. (151 h) is a well characterized species, above something like *ostrinus* (151 f), the blue *adela*, rather very much confined, with a distinct red anal spot and a broad, blackish-brown costal margin. The under surface is brown, not greenish, between the postdiscal transverse line and the distal margin, in the whole length, a brownish macular line extends, bordered on both sides by whitish. The costal margin of the hindwing scarcely bulged out, the forewings without any scent-spot. Amazon District.

Th. syedra Hew. (151 e). A smaller species, above almost like *strephon* (151 d), beneath entirely light *syedra*, brownish, the ♀ somewhat darker, the lines arranged about as in *cyllarus* (151 f), the costal margin of the hindwing strongly convex, covering the yellowish, large scent-spot; on the hindwings the antemarginal, macular line begins at the costal margin with 2 isolated brown spots. Guatemala to the Amazon.

Th. enenia Hew. (155 h) is allied to the preceding; above more greenish-blue, beneath very light *enenia*, grey, towards the apex on the forewings reddish-brown, the lines very much like those in *syedra* (151 e), the marginal area of the hindwings extensively whitish, the postdiscal broadly white, the submarginal line consisting of tiny brown spots, the second of which beginning from the costal margin is the largest. Brazil.

Th. rickmani Schs. seems to belong here and to resemble *purpurantes* (151 g); on the forewings the *rickmani*, blue colour is confined to the surroundings of the submedian, the hindwings have only a narrowly black costal and distal margin; above the anal lobe in which there is no red there is a white spot. Beneath light olive-brown; on the hindwings the postdiscal line runs rectilinearly from the subcostal line to the lower radial; the anal red very broadly developed beyond the upper median vein. Colombia.

Th. imma Prittw. is a species that has hitherto not been identified, described according to a *imma*, single ♀ which may belong here, but also to the *orcynia*-group (p. 788). Size and shape of *Th. quercus* (Vol. I, t. 74 d); above blackish-brown, in the basal part of the forewing and on the hindwing extensively dull sky-blue. Beneath light ashy-grey with the 2 usual white transverse lines reaching almost the proximal margin also on the forewings and touching each other on the hindwings in cell 4; the spot on the tail is red, the anal spot black, only proximally dusted in red. Patria?

Th. metanira Hew. (151 c) also belongs yet into this group, in spite of the deviating scent-spot on *metanira*, the upper surface of the forewing which is situated in and behind the cell-end; it is dark brownish-grey, in the proximal part a jet-black pupil. Forewings above rather extensively radiantly greenish-blue. Beneath the forewings are unmarked greyish-brown, without the scent-spot, the hindwings marked as in *perola* (151 g, h), but without a convex costal margin and with very slightly developed red, in the ♀ almost entirely without any red, but instead of it more copiously dusted in greenish, so that it also resembles the *atema*-group (= *narbal*-group, p. 765, t. 150 h—k). From the Amazon to Peru.

Th. lorea Mschl. which has remained unknown to me, seems to be the most closely allied to the *lorea*, preceding, unless it coincides with it. It is described to be above azure with a broadly blackish-brown costal margin, apex and distal margin, at the end of the discocellular with a round, blackish-brown scent-spot. Beneath dark brownish-grey, the marking of the hindwings is as in the preceding, the forewings likewise as they are there, without any markings. Surinam.

Th. ericeta Hew. (= *munatia* Hew.) (151 d). Above of a magnificent radiantly blue like *strephon*, *ericeta*, with the same broadly black apex of the forewing; the costal margin of the hindwing has a polished black lustre, suffused by indigo-blue. The under surface is variable, brown or grey, the proximal white line diverges far

inside towards the costal margin as in *strephon*, also on the forewings which exhibit a whitish inner-marginal part and a large, somewhat darker brown scent-spot. Guatemala, Panama, Colombia.

pulchritudo. **Th. pulchritudo** Drc. (151 e) is allied to the preceding, above more extensively blue with a small-polished spot on the hindwing, entirely covered by the forewing; the under surface is greenish-blue, not as in the figure on which the silvery greenish-blue opalescent spot in the discocellular is neither reproduced at all, below it a large, brownish scent-spot, the lines quite similar as in *ericeta*, only towards the costal margin not so greatly divergent; the red anal spots are almost entirely absent. Amazon, Colombia (Rio Negro: Coll. FASSL).

carteia. **Th. carteia** Hew. (151 h, i) is above scarcely distinguishable from *ericeta* (151 d), the polished spot is very extensive, opalescent olive-green. Beneath brownish-grey with a large, blackish-brown, silky spot on the forewings; the costal margin of the hindwing is very strongly convex, the lines as in *ambrax* (151 f), only placed a little more towards the margin. Ecuador, Amazon.

zigira. **Th. zigira** Hew. (151 i) is much smaller than *carteia* with a more narrowly black apex of the forewing, otherwise very similar; also beneath similarly marked, but the ground of the wings is of a purer light grey, the hindwings at the distal margin more dusted in white. Amazon, Venezuela, Peru.

falerina. **Th. falerina** Hew. (151 i) we include here yet, although it makes a very different impression; much smaller, above deep violet-blue with very broad black distal margins and a brown-yellow, polished, unsealed spot at the base of the hindwing towards the costal margin. The under surface is greenish brownish-grey, the costal margin of the hindwing strongly convex, covering a lustrous, darker spot of the proximal margin of the forewing. On the hindwings the postdiscal begins with an isolated black spot, towards the base of it is a second, distally white spot. Guiana, Amazon.

71. Latagus-Group.

latagus. **Th. latagus** Godm. & Salv. (155 h) has certain relations to a part of the preceding group by the black spot of the costal margin of the hindwing above, being partly covered by the expanded proximal margin of the forewing; the ground-colour above is lustrous blue with a moderately broad black apex and a narrow distal margin, beneath brownish-grey with 4 white transverse lines before the margin of the hindwing and a red spot of the tail. Panama.

oratus. **Th. oratus** Godm. & Salv. (155 h) we append directly here; it is above silky blue, the hindwings with a yellowish-brown subcostal stigma, beneath grey with an irregular grey, proximally white bordered discal line and an indistinct, dark submarginal line bordered on both sides by white. The proximal margin of the forewing opalescent bluish-green. Mexico, Guatemala.

72. Gadira-Group.

gadira. **Th. gadira** Hew. (155 h) is without tails, above lustrous ultramarine-blue with a large, oval, brown scent-spot and a moderately broad, velvety-black margin. Beneath light brownish-grey with white lunular lines and 2 orange-red, black-pupilled anal spots. The ♀ is darker violettish-blue, particularly on the forewings very broadly bordered by blackish-brown. Guatemala to Colombia.

norax. **Th. norax** Godm. & Salv. (155 h) is smaller, lighter blue, with broader black margins and a rounder scent-spot; the under surface is somewhat lighter, striated with many white lunular lines. Guatemala to Colombia.

levis. **Th. levis** Drc. (155 h) greatly resembles *norax* above, but the scent-spot is smaller, round and black; beneath more yellowish-brown in the distal part, in the larger basal half sharply delimited darker brown; the markings on the whole similar, but not white, but brownish, the hindwing besides with an undulate, dark-brown median band. Amazon.

conchylum. **Th. conchylum** Drc. (155 i) also like *norax* with a somewhat narrower black margin; the scent-spot is much narrower and lighter. The red spots of the hindwing are almost entirely absent, and only in the dark-brown, towards the base blue-reflecting ♀ they are somewhat more visible. Brazil to Paraguay.

minthe. **Th. minthe** Godm. & Salv. (155 i) resembles *gadira*, being of a somewhat lighter, silky-lustrous blue and very easily recognizable by the under surface of the forewings which is opalescent blue in the inner-marginal half. From Mexico.

elana. **Th. elana** Hew. (152 g) resembles above *gadira* with its magnificent blue, but it has a tail and broader black margins. Beneath brownish-grey, at the proximal margin of the forewing lighter, the marking likewise resembles somewhat the said species, but it also resembles *punctum* (152 d) by a small black and white dot in the middle of the costal margin of the hindwing. Colombia to Brazil.

mulsus. **Th. mulsus** Drc. (152 d) is above deeper purple-blue than the preceding and has beneath entirely unmarked forewings, and the dot of the costal margin of the hindwing is absent, too. It likewise has a long tail. Amazon.

Th. vieca Schs., apparently described according to a ♀, larger than *gadira*, without a tail, above *vieca*. blackish-grey, in the basal inner-marginal part of the forewing lilac-grey, the hindwings white, dusted in lilac-blue with a blackish-grey costal margin and distal margin. Beneath light brown, marked like *conchylum* (155 i), in the median area broad whitish with a white costal marginal streak. Venezuela.

73. Laeta-Group (*Erora* Scudd.).

Th. laeta Edw. (= *clothilde* ♀ Edw.) (155 i) is the typical representative of a small group probably *laeta*. comprising only this one species, but varying a great deal. The name-type is distributed in North America but apparently very rare. Above brown, towards the base suffused by blue; beneath fawn-coloured with post-discal bands and such at the margin of the hindwings, composed of tiny, orange-red, distally white-bordered spots. It flies from Quebec to West Virginia and Arizona; there are no details known as to its life-history. — **quaderna** Hew. (155 i) from Mexico is above abundantly dusted in a violettish-blue, with small dark spots before *quaderna*. the distal margin of the hindwings and orange fringes. The colour beneath is of a shade like a grey-horse, distally with a greenish shine. This is probably the ♀ of **attalion** Godm. & Salv. (155 i) which is quite brown above, *attalion*. with tiny, blue, submarginal spots of the hindwings. — **aura** Godm. & Salv. (155 i) from Costa Rica and Panama *aura*. is likewise similar, but black above, the hindwings only in the centre blue without a blue submarginal; beneath the colour is more bluish-grey, without the red small submarginal spots, and the median line of the forewing is placed nearer to the distal margin.

Th. phrosine Drc. (146 e) is a peculiar small species, which perhaps belongs into this group; above *phrosine*. dark-brown, the fringes of the hindwings white. Beneath white with a faint silvery reflection, in the disc of the forewing a bluish tinge; the postdiscal band consists of single, tiny, copper-brown spots, on the hindwings there are besides minute submarginal dots. Abdomen beneath white. Peru, Bolivia.

Th. castrena Jones (156 d) differs above from *phrosine* by lilac-blue scales being strewn on the base *castrena*. of the proximal margin of the forewing and on the hindwings. The ground-colour beneath is light lilac-blue, in the ♀ more yellowish-grey with a similar marking as in the former, though more copious. Castro (Paraná).

74. Nana-Group.

Th. nana Fldr. (155 k) is a most peculiar species not to be mistaken for any other species. The shape *nana*. of the wings peculiarly high. The colour is above dull indigo-blue with a slight lilac lustre; the whole costal-marginal half of the hindwing is of a light-grey lustre and in its basal half there is a roundish scent-spot of the same colour. Beneath light bluish-green with a faint lilac shine, in the inner-marginal area of the forewings brownish-grey; on the hindwings with a fine white lunular line, towards the inner-margin proximally bordered by blackish, at the acute anal angle a small black spot; there is no tail. Forehead brown, palpi at the sides green. Colombia.

Th. facuna Hew. (156 a) is larger, of a more slender shape of the wings. Forewings above blackish- *facuna*. brown, in the basal inner-marginal part as far as the middle of the cell suffused by indigo-blue; hindwings in the disc of a violettish-blue lustre, from which the large brown scent-spot stands out in bold relief, filling up the whole basal part, inclusive of the cell; the costal margin itself is lustrous lighter brownish. The ♀ is duller and more extensively blue. Beneath emerald-green; forewings unmarked, in the inner-marginal part brown; the hindwings with an indistinct postdiscal line of blackish, distally lighter, though not white-bordered, small streak-spots. Fringes brownish, near the anal angle black, at the base white; at the tip a small black spot. Forehead, palpi and tibiae green, legs black, wreathed in white. Rio Grande.

Th. senta sp. nov. (156 a) greatly approximates the preceding, it is larger, the distal margin of the *senta*. hindwings more convex, the wings dusted in a purer blue, the hindwings much more extensively, because the distal and proximal margins are only narrowly black. The costal margin of the hindwings dark-brown, in its basal half we notice the much smaller, red-brown lustrous, though little contrasting scent-spot of an oblong shape. Beneath the green is a shade more yellow, of the postdiscal line there is only the beginning of a W left at the anal angle, behind it is a small black spot. Forehead, palpi and femur green. 1 ♂ from Colombia (Cañon del Tolima) from the Coll. FASSL.

Th. opisena Drc. (155 k) is a smaller, ultramarine species with a broadly velvety-black apex and *opisena*. distal margin. Beneath emerald-green, often only with the beginnings of a postdiscal at the proximal angle of the hindwings, which, however, may also be extended as far as the costal margin; a small spot and the fringes at the anal angle are black, occasionally with an orange-red upper tinge. Colombia.

Th. biblia Hew. (155 k). Above plainly brown, beneath of delicate bluish green, like all the following *biblia*. species with a peculiar lilac-blue shine of a silky or mother-of-pearl lustre; at the anal angle of the hindwing a tiny black spot. Amazon.

Th. ares Godm. & Salv. (155 k) greatly approximates the preceding, being above suffused with a *ares*. purple-violet; on the green under surface there is an indistinct, whitish postdiscal and also at the cell-end a streak. Forehead green. Guatemala, Amazon.

- smaragdus*. **Th. smaragdus** Drc. (155 a) exhibits above a purple-violet reflection like *ares*. Beneath the postdiscal is more distinct, also on the forewings there are traces of it; it is immediately recognizable by the white fringes beneath being velvety-black at the base. Colombia (Rio Aguaca Valley), Brazil.
- semones*. **Th. semones** Godm. & Salv. (155 k) differs from the preceding by the leaden-lustrous, indigo-coloured upper surface, black forehead and entirely unmarked green under surface. Mexico.
- subflorens*. **Th. subflorens** Schs. (156 a) resembles somewhat the preceding above, but it is strewn with a purer metallic blue, with a broadly black apex of the forewing, green forehead and beneath discal lines composed of small, high lunular spots on both wings, but on the forewings only indicated, between the median veins of the hindwings also traces of a small orange-red spot, and a light discal streak. Costa Rica to Colombia.
- camp t.* **Th. camp** Jones (156 a) is above dull blackish-blue, distally purer black, hindwings with narrowly black margins, fringes brown. Beneath very pale green, with a particularly intense lilac-blue shine. Forewings unmarked, hindwings with a greyish-white discal streak and the discal line as in *subflorens*, but distinct only towards the proximal margin; in the anal lobe a black spot bordered above and beneath by white, between the median veins an orange-red, black-ringed spot; palpi white, forehead green. Paraná.
- quassa*. **Th. quassa** sp. nov. (156 a) greatly approximates the preceding, but it is above purple-brown, the hair of the proximal margin and the fringes of the hindwings snow-white. The under surface is the same, the postdiscal band as far as the costal margin very distinct, composed of high, proximally brown, distally white, lunae, also present on the forewing near the costal margin; fringes of the hindwing also beneath white, but with a deep velvety-black basal line. The forehead is black. 1 ♂ from Sa. Catharina (Coll. WERNICKE).

75. Schausi-Group.

- schausi*. **Th. schausi** Godm. & Salv. (156 a) is the typical representative of an extremely peculiar, small and very little known group the species of which are apparently all very rare hitherto. Above metallic ultramarine-blue, at the distal margin broadly brownish-black. Beneath blackish-grey, on the hindwings with jet-black veins. The disc of the forewing metallic blue, a whitish spot at the base of the costal margin of the hindwing, at the base of which there is a small, scarlet spot surrounded by some opalescent blue scales. Mexico, Nicaragua.
- miranda*. **Th. miranda** Godm. & Salv. (156 a) resembles the preceding, the anal angle of the hindwings is somewhat more drawn forwards, the wings above more purple; beneath the apex of the forewing exhibits a yellowish-white spot, the hindwings a tripartite, subapical spot, the base of the cell and the proximal margin likewise a yellowish-white spot; the abdomen is white beneath. Amazon, São Paulo.
- crepundia*. **Th. crepundia** Drc. (156 b) is above dull olive-brown, towards the base with an indigo-blue reflection. Beneath likewise olive-brown, with a yellowish-white, brown-veined apex of both wings, the forewings in and below the cell opalescent greyish-blue; at the base of the hindwings a large red spot. Peru.
- insignis*. **Th. insignis** Godm. & Salv. (156 a). Only the ♀ is known: above blackish-brown; beneath the forewings are just the same, at the proximal margin lighter with a yellowish-white apical spot; the hindwings are orange-yellow, with broad blackish-brown veins and small brownish spots at the costal angle and between and below the median veins. The bases of all the wings spotted in orange-red. Mexico, Panama.

76. Sesara-Group.

- sesara*. **Th. sesara** Godm. & Salv. (156 a) is an isolated species which would have to be renamed, if it remains in the large collective genus, since the same authors have already before denominated a *Thecla* with the same name. Above the forewings are blackish-brown, the hindwings blue with a fine, bluish-white marginal line in the black anal part, in which there is a reddish-brown spot; a small, short tail. Beneath silky brown, in the distal part lighter and more reddish; the postdiscal blackish-brown, on the hindwings irregular; in the anal part no red spots, only 2 black dots; fringes rusty-brown. From Mexico.

77. Orobiana-Group.

- orobia*. **Th. orobia** Hew. (152 a) is above deep peacock-blue with black veins and narrowly black margins. Beneath deep purple-brown, the proximal margin of the forewing light-grey; in the lower cell-half and behind it between the median veins scales of a brilliant bluish-green; at the costal margin in the middle and before the apex one whitish blurred spot each; from the proximal one there emanates a row of white dots. Hindwings with a blue basal dot and a postdiscal row of similar dots. Anal angle dusted in golden-green. Panama, Colombia, Bolivia, Venezuela, Amazon.
- orobiana*. **Th. orobiana** Hew. (152 a) is doubtful as to its being justified to be called a species, the chief mark is the absence of the blue stripe through the disc of the forewing beneath; the other marks stated are: larger,

with a broader black margin, above and beneath absent white costal-marginal diffuse spots vary greatly, if larger series are to be looked at. It lies before me from the Amazon and Colombia.

Th. orocana Drc. (156 b), however, is undoubtedly a different species; it has above all no tail, but *orocana*. an extended, inwardly curved anal lobe of the hindwing, as some species of the *amyntor*-group (p. 762). The colour above is a lighter, radiant greenish-blue, the apex of the forewing is very broad black; whereas in *orobita* and *orobiana* the blue colour of the hindwing above the upper radial vein extends constantly in the shape of a bow into the brown costal margin, it runs here below the said vein straight on to the distal margin. Beneath there is little difference: the blue discal stripe of the forewing is absent, on the hindwings there are at the anal angle but very sparse golden-green scales. Peru; Colombia (Cañon del Tolima).

78. Hyacinthus-Group.

Th. hyacinthus Cr. (156 b) is above sky-blue with a narrow black margin; beneath the forewings *hyacinthus*. are greenish-blue with a narrow black margin and two bands before the distal margin, the hindwings exhibit a yellowish-brownish band from the middle of the proximal margin to the costal angle, broadly bordered in black, and black spots before the distal margin. West Indies.

Th. pholeus Cr. (= *philanthus* Stoll) (156 b) is a little similar, above peacock-blue, the ♀ brown; *pholeus*. on the under surface the ♂ is greenish-blue, the ♀ yellowish-grey with black bands and a yellowish-brownish stripe on the hindwings as in the preceding. — Whereas the northern specimens from Surinam and Cayenne always exhibit some small, metallic greenish-blue spots in the median black band of the hindwing, the southern specimens from Brazil and Colombia are always without them, they may therefore be denominated **meridionalis** *form. nov.* (156 b). — At both the habitats there occur small ♂♂ with a brown ground-colour above like the ♀♀: **feminalis** *form. nov.* *meridionalis*. *feminalis*.

Th. selina Hew. (156 b) cannot be justly called a distinct species, as long as a ♂ fitting to it has not *selina*. been ascertained. The ♀ does not differ from that of *pholeus* above, but beneath the forewings are unicolorously brown with 2 darker submarginal bands; on the hindwings the costal margin next to the base is broad red-brown, otherwise as in *pholeus*. The most positive assertion for the qualification of the species is the fact that in the black median band there are always greenish-blue spots which are forever absent in southern specimens of *pholeus*. Brazil, Ecuador.

Th. nautes Cr. (153 b) is larger, above darker with a small, darkbrown scent-spot and broadly darkened *nautes*. veins. The under surface is very characteristic and unmistakable. In the ♂ the proximal half of the forewing is peacock-blue, but not in the ♀ which is also above brown. Ecuador, Amazon.

Th. elis Cr. (156 c) preponderantly differs by its under surface; the forewing exhibits in the disc *elis*. 3 or 4 black, blue-pupilled eye-spots standing below each other; on the hindwing there is at the costal margin nearer to the base another black, blue-pupilled eye-spot; the yellowish-grey longitudinal stripe extends towards the costal angle, in *nautes* between the radial veins to the distal margin. Brazil.

Th. bactriana Hew. (156 c) we insert here on account of the under surface resembling somewhat *bactriana*. *pholeus*, though it is otherwise quite isolated. Above light-blue with a broadly black apex and a large, light-ringed scent-spot. Beneath yellowish-brownish with similar spots and bands as *pholeus*. Amazon.

79. Empusa-Group.

Th. empusa Hew. (= *tympania* Hew., *bethulia* Hew., *halciones* Bllr.) (156 c) is above deep blue, *empusa*. in the larger apical half black. The under surface is light grey with fine brown postdiscal lines, distally bordered by white, proximally by a very fine orange-yellow, on the hindwing beginning with an outwardly displaced streak-spot at the costa; quite indistinct, small, submarginal lunular spots are only visible on the hindwing by being on both sides dusted in white; at the anal angle there is a small black spot, being above bordered at first by white, then by orange; proximally follows a white-dusted part, then between the median veins again an orange, small spot. Distributed from Mexico to the Amazon and Bolivia.

Th. purpuriticus Drc. (156 c) is above just the same, beneath darker, on the hindwings between the *purpuriticus*. median veins before the border much more extensively dusted by orange, the submarginal shades placed nearer to the postdiscal and more proximally. Colombia.

Th. tarena Hew. (156 c) is most similar, above hardly different, but the costal margin of the hindwing *tarena*. is broadly brown. The under surface is more brown, the lines as in *empusa*, but more indistinct, the red spot of the tail placed more proximally. Guiana.

Th. gentiana Drc. (156 d) differs above from *tarena* by a very large, black, oval scent-spot being proxi- *gentiana*. mally surrounded by slate-blue scales. Beneath like the preceding, the lines still weaker and a little straighter, the red spot removed more towards the margin. Colombia.

- lemuria*. **Th. lemuria** Hew. (156 d) is considerably smaller, above deep ultramarine-blue, with an oval, dark-brown scent-spot behind the cell and a moderately broad black apex, a narrow distal margin. Beneath light brownish-grey, marked like *empusa*. Colombia, Brazil.
- collustra*. **Th. collustra** Drc. (156 d) does not differ beneath, but above it is greyish-black, of a purple lustre, without a scent-spot, the hindwing in the proximal half more indigo-blue with a small red anal spot. Trinidad.
- argerona*. **Th. argerona** Hew. (156 e) is on the forewings above only at the base and in the disc of the hindwing somewhat darker, more indigo-blue. Beneath light reddish-grey, marked like the preceding, on the forewing, only a short postdiscal extending neither to the costal margin nor to the proximal margin; on the hindwing the grey spot between the spot of the tail and the anal spot is above also bordered by red. Brazil.
- melma*. **Th. melma** Schs. (156 d) seems to belong into the same group. Above of a purer blue with a less extensive apical black than in *empusa*, beneath more olive-brownish, the lines more distinct and broader, the space between the anal spot and the spot of the tail dusted in a bluish white. Costa Rica, Panama.
- ophia*. **Th. ophia** Hew. (156 e) is above extensively blackish-brown, only towards the base and proximal margin greenish-blue with a large, dark, hardly visible discal spot without any scent-scales, the forewings entirely blue except the broad costal margin and narrow distal margin. Beneath brownish, marked like *lemuria* (156 e), but somewhat more prominent, the submarginal macular bands more distinct, also on the forewing. Amazon.
- laconia*. **Th. laconia** Hew. (156 e) looks above just the same, but it has a large, oval scent-spot. Beneath lighter, the lines finer, lighter, more strongly broken, more remote from the border. Amazon.
- cupa*. **Th. cupa** Drc. (156 e) differs from *laconia* by the blue entering into the cell of the forewing and a broader black costal margin of the hindwing; at the cell-end of the forewing lies only a small, round, indistinct scent-spot instead of the large oval one in *laconia*. The under surface is lighter, the discal bands proximally bordered by brown, on the forewing in the lower half removed more towards the margin. Rio Grande.
- gnosia*. **Th. gnosia** Hew. (156 e) probably belongs to the same group, it has a rounder shape of the wings, is smaller, above of a purer, though more subdued blue, the ♀ brownish, with violettish-blue hindwings. The under surface entirely resembles that of the preceding. Colombia, Peru, Bolivia.

80. Echion-Group.

- echion*. **Th. echion** L. (= *crolus* Cr.) (156 e, f) is a very variable species: above dull-lustrous indigo-blue with a very broad blackish-brown apex of the forewing and costal margin of the hindwing; the larger distal half of the cell is filled up with scarcely contrasting, dark-brown scent-scales of a slight steel-blue lustre. The ♀ is much duller with a white marginal line on the hindwings in the anal direction. Beneath lighter or darker brownish-grey, particularly in the ♀ often whitish-grey, in the ♂ the disc of the forewing is more brown, in some places clouded in a somewhat darker colour, the forewings with 2 lines, the hindwings with roundish, copper-coloured to light-orange spots, bordered by black, before the distal margin a dentate line, and the usual orange-red, black-pupilled, small spots. Very common from Mexico to South Brazil. — A smaller form flying in Mexico, *echiolus* form. nov. (156 f) shows the spots on the hindwings beneath more subdued, more pale-orange with a disappearing dark bordering.
- crolinus*. **Th. crolinus** Btlr. (156 f) is similar, but above much more extensively and brilliantly blue, so that the whole proximal half of the cell remains blue, behind it a four-cornered, black discal spot. Beneath not essentially different, but the spots on the hindwings are not so round, but more oblong, so that more of a transverse band is produced. Mexico to Panama.
- vomiba*. **Th. vomiba** Schs. seems to be closely allied to *crolinus*, on the forewing the blue is confined to an inner-marginal stripe, beneath it differs by a more complete additional basal of the hindwing, which is somewhat interrupted only above and below the cell. Expanse of wings: 22 mm. Petropolis in South Brazil.
- venustus*. **Th. venustus** Drc. (156 f) is above like *crolinus*, the fringes of the forewing copper-brown. Beneath darker brown, on the forewings the postdiscal band is much straighter; we do not find any real difference from *crolinus*. Described from Brazil.
- labes*. **Th. labes** Drc. (156 f) is smaller, above dull brown with a large black scent-spot, the hindwings only in the proximal half are slightly tinged in a greyish blue. Beneath there is no difference from *echion*; it is perhaps only a small form of it, from Trinidad.
- philinna*. **Th. philinna** Hew. (= *unilinea* Kaye) (156 g). Above similar to *echion*, but with quite a different scent-spot in two parts being placed almost vertically above each other: the upper part grey, the lower one brown. The under surface is likewise similar, but without the basal spots of the hindwings and extremely variable, white to brownish-grey, the spots themselves sometimes golden-yellow, sometimes copper-orange, or dul

brownish-grey, sometimes very large, sometimes very small. Just as common as *echion*. From Mexico to South Brazil. — The northernmost specimens from Mexico, *greppa* Dyar, have an almost white under surface. *greppa*.

Th. giapor Schs. (160 d). Above blue as *crolinus*, but with the double scent-spot of the preceding, *giapor*. the distal, grey portion smaller. The under surface likewise as in *crolinus*, but with a fine streak at the cell-end, the spots on the hindwings more coherent, linear, the postdiscal straight from the costal margin to the lower radial vein. São Paulo.

Th. fostera Schs. is unknown to me, but it presumably belongs here. Only the ♀ is known: above *fostera*. brown, the forewings only at the proximal margin, the hindwings more extensively dull light-blue; at the distal margin of the latter there are in the anal part 3 small red spots, above them some black ones. Beneath light-grey with a fine, red marginal line and a red streak at the cell-end; on the forewings a row of red spots from the costal margin to the lower median vein, the second spot from below inwardly displaced; on the hindwings a red cell-spot and one above it, postdiscally a row of large, red spots, forming a broken W at the proximal margin; at the border the 2 usual red spots; above the upper median vein yet a third, smaller one. On the head a red spot. São Paulo.

Th. cydrara Hew. (156 g) and its nearest allies we most appropriately combine with the *echion*-group *cydrara*. to which they exhibit many relations. Above almost like *echion*, only somewhat more metallic greenish-blue. Beneath very easily recognizable by the large, chocolate-brown, triangular spot at the costal margin of the forewing. Very common and widely distributed from Mexico to the Amazon.

Th. ufentina Hew. (156 g) is above considerably more extensively coloured in a radiant, metallic *ufentina*. greenish-blue with a scent-spot in the cell. Beneath the forewings are quite brown with a lilac reflection, the hindwings have a large, brown spot in the basal costal-marginal part. São Paulo.

Th. viceta Hew. (156 g) has almost quite brown forewings and a very small scent-spot, only the proximal margin exhibits a narrow blue tinge, the hindwings are more extensively blue. Beneath like the preceding, only the brown costal-marginal spot is larger, and at the costal-angle there is also a brown spot. Amazon (Santarem).

Th. opalia Hew. (156 g, h) is above somewhat more extensively blue than the preceding, beneath *opalia*. quite purple-brown with white macular rows. Described from the Amazon.

Th. verania Hew. (156 h) initiates another subordinate group of mostly smaller species, which is likewise closely allied to *echion*; the copper-brown basal spots of the hindwings beneath are here partly united with the proximally displaced postdiscal. *verania* is above radiantly light blue with a very narrow, black distal margin and a but slightly broader apex, without a scent-spot. On the hindwing beneath the 2 usual, orange-red anal-spots are absent. Amazon, Ecuador and Bolivia.

Th. fabulla Hew. (156 h) resembles *philinna* (156 h) above and has likewise a double scent-spot, the proximal lower part of which little contrasts with the brownish-black ground, the upper part being smaller and lighter grey. Beneath on the hindwings almost like *verania*, only darker brownish-grey, on the forewings with a straight, brown-red postdiscal band; in the anal angle we do not notice the distinct W of the said species, but only a triangular, brown-red spot; at the anal angle and between the tails 2 orange spots. Guiana, Venezuela, Amazon.

Th. dolium Hew. greatly resembles the preceding, more purple blue and duller, with an only single *dolium*. scent-spot at the cell-end-beneath lighter, the copper-red spots bordered with a more distinct white. Honduras.

Th. ceglusa Hew. (156 h) is above more extensively blue with a small, indistinct, brown scent-spot *ceglusa*. behind the cell and a small red anal spot. The under surface is very much like that of *fabulla*. Amazon.

Th. petilla Hew. (156 h) has much more extensively blackish-brown forewings which are blue only *petilla*. at the proximal margin, without a scent-spot. Hindwings lustrous greenish-blue. The under surface has a reddish or lilac tinge, the distinct, brown, submarginal, small lunular spots are on both sides bordered by white, the spots of the hindwings arranged about as in *fabulla*, but larger, the red anal spots large; on the forewing the postdiscal band is longer and more parted into small spots, the uppermost of which at the costal margin is quite isolated. Amazon.

Th. phobe Godm. & Salv. (156 h) is discernible from the preceding by the red-brown colour being *phobe*. on the hindwings much more extensive and flown together and reaching almost to the margin. Mexico, Guatemala.

Th. velina Hew. (156 i) likewise greatly resembles the preceding, but here the red-brown is still more *velina*. extensive and reaches as far as near the base of the hindwings, the ground-colour being lighter, almost whitish. Amazon.

81. Dindymus-Group.

Th. dindymus Cr. (= sphinx ♂ Godt.) (156 i) is allied to the *sophocles*-group by the under surface, *dindymus*. but above it is extensively brilliant blue, without a scent-spot, with a but little brownish-black apex. Beneath

very light whitish-grey with white, proximally grey-tinged, postdiscal dentate lines and grey submarginal lunae being on both sides bordered by white; the small orange anal spots are very small. Amazon, Bolivia, Peru.

stilbia. **Th. stilbia** Hew. (156 i) resembles the preceding above, but beneath it is easily discernible by the postdiscal band being composed of crescents and exhibiting at the costal margin a separate small spot, which is removed more towards the margin. Brazil (Espírito Santo).

villia. **Th. villia** Hew. (156 i) belongs likewise here, the ♀ above more greyish-brown, towards the base with a dull ultramarine-blue tinge; the under surface is also very similar, somewhat more brownish with a lilac shine; on the forewings the postdiscal band extends to the proximal margin, on the hindwings it runs a little more straight, and there is a whitish discal streak indicated; the orange spot of the tail is larger, pupilled with a black triangle. Honduras to the Amazon.

proba. **Th. proba** Godm. & Salv. (156 i) is above still more extensively and lighter blue than *dindymus*, beneath whitish, without any marking at all. From Panama.

lenitas. **Th. lenitas** Drc. (156 i) is above monotonously dull-brown, only at the proximal margin quite narrowly dusted with blue, the hindwings in the disc a little more extensively violettish-blue. Beneath light brownish-grey, marked like *dindymus*, but the orange anal spots are absent altogether. Brazil to Paraguay.

strenua. **Th. strenua** Hew. (156 i) may also be yet included here. It differs above from the similar preceding species by a somewhat more extensive and brighter blue colour; beneath the ground-colour is more red-brownish, the white, proximally dark-bordered lines are removed a little more inwardly, also the red spot between the median veins; between it and the small anal spot the ground is dusted in a bluish white. Brazil.

heloisa. **Th. heloisa** Mschr. is a species that has remained unknown, described according to a ♀: above brown, on the hindwings with a grey tinge, towards the base lustrous bluish-grey with a red anal spot. Beneath light greyish-yellow; the postdiscal white, proximally bordered by brown, on the forewings removed inwardly below the lower median vein, on the hindwings towards the proximal margin forming a W; a series of white submarginal lunular spots is on the forewings only visible between the radial veins, on the hindwings interrupted above the upper radial vein; the small red anal spots proximally bordered by white; between the lower radial veins the white submarginal lunae are double. Length of forewings: 16 mm. Paramaribo.

purissima. **Th. purissima** sp. nov. (156 k) is only half as large as *dindymus*, above in the ♀ very much like it, dull lustrous greyish-blue, distally broadly grey. Beneath quite snow-white with an extremely fine, blackish postdiscal running almost the same, only less curved, more parallel to the border; the submarginal lunae the same, the tiny spot of the tail orange-red, between it and the blackish anal spot a small, grey, roundish spot. 1 ♀ from Panama (Lino) from the Coll. FASSL.

82. Orcynia-Group.

orcynia. **Th. orcynia** Hew. (= *anthracia* Hew., *aunia* Hew.) (156 k) has a somewhat variably blue upper surface, sometimes more violet, sometimes more greenish-blue, and the larger apical half of the forewing black; at the anal angle of the hindwing an indistinct, small, red spot. Beneath likewise variable in a more grey or brown tinge with a mostly very clear white postdiscal being proximally tinged in a fine darker colour, forming inwardly a V on the forewing below the lower median vein, whereas on the hindwings it is displaced outwardly between the radial veins and forms a flat W at the anal angle; brownish submarginal lunae are on both sides dusted cloud-like in white, the broadest above the median veins; the orange anal spots very small; a white double streak at the cell-end may be present or absent. Very common and most widely distributed from Mexico to Venezuela, Colombia and Bolivia.

catharina. **Th. catharina** sp. nov. (156 k) is very closely allied to the preceding, but I take it to be decidedly a different species. It is above not quite as extensively dull violettish-blue, the apex very broad blackish-brown. Beneath the postdiscal line on the forewing is parallel to the distal margin and composed of flat lunae, in all the specimens seen of *orcynia* running nearer to the anal angle and much more linear; on the hindwings there is instead of the two white cell-end-streaks one dark one, the two orange-red anal spots are better developed. According to 2 fresh ♂♂ from Sa. Catharina from the Coll. WERNICKE.

ahola. **Th. ahola** Hew. (= *cordelia* Hew.) (156 k) is above decidedly more lustrous greenish-blue and beneath easily distinguishable from *orcynia* by the white, basal, transverse line on the hindwing. Mexico, Colombia, Venezuela.

marmoris. **Th. marmoris** Drc. does not differ above from *ahola*; beneath the forewings exhibit a double, white cell-end-streak, the postdiscal line is more undulate, and before the distal margin there are dark circular spots, surrounded by white, no crescents. Colombia.

Th. fidelia Hew. (156 k) is above magnificently radiant light turquoise-green, the apex of the forewing *fidelia*, not so extensively black, beneath scarcely different from *orecynia*. Venezuela, Bolivia.

Th. keila Hew. (= *parasia* Hew.) (157 a) resembles *orecynia* above, but it has a long oval scent-spot *keila*, in the cell, being very little conspicuous; the under surface is likewise similar, but the postdiscal on the hindwing is towards the costal margin much broader white, on both wings somewhat nearer to the margin. Nicaragua, Guatemala.

Th. humber Schs. is closely allied to the preceding, above metallic blue; the costal margin, apex *humber*, and distal margin about just as extensively black as in *fidelia*; without a scent-spot, with a small, red and black anal spot of the hindwing. Beneath light brownish-grey, marked like the preceding, but the postdiscal runs on the hindwings from the costal margin in a straight line to the lower radial, then only it is broken and forms a W at the proximal margin. Expanse of wings: 23 mm. Venezuela.

Th. thoria Hew. (152 e) likewise approximates *keila*, above more violettish-blue, on the forewings *thoria*, confined to a stripe parallel to the proximal margin; the scent-spot is double: in the cell black, behind it red-brown. The under surface is more reddish-brown, the cell-end-streaks are absent, on the hindwings there is often a white streak-spot in the middle of the costal margin. The ♀ is duller bluish-grey. Venezuela.

Th. bassania Hew. (157 a) entirely resembles *ahola* (156 k) above, but the red-brown anal spot is *bassania*, perhaps more strongly developed. Beneath on the darker brownish-grey ground all the transverse lines are double and consist of regular semi-bows. Mexico to Panama.

Th. gabatha Hew. (= *balius* Godm. & Salv.) (157 a) is closely allied to *keila* (156 k) and has the same *gabatha*, scent-spot, but it is considerably larger and has much longer-stretched hindwings with a large, red anal spot; the ♀ is duller and lighter blue with dark, marginal spots being partly bordered by orange-red, of the hindwings; also beneath very similar. The forehead is red. Guatemala, Brit. Honduras, Colombia.

Th. sylea Hew. (157 a) has likewise a red forehead; it is above duller blue, inclusive of the cell, as the *sylea*, scent-spot of the preceding is absent, and the shape of the wings is not so long-stretched. Beneath marked almost just the same, only the postdiscal, at the costal margin of the hindwing, is placed more towards the base and proximally tinged in red, not black. Amazon.

Th. iopas Godm. & Salv. (157 b) is placed here by the authors, but to me it seems almost to be more *iopas*, closely allied to the *galliena*-group (p. 791). Wings intensely cyanic-blue with black margins, the anal lobe with a red spot. Beneath red-brown with blackish, distally white postdiscal lines being placed very near to the border, on the hindwings broken, at the anal angle angled; the anal lobe is black, inwards with a red dot, next to it a black, white-dusted spot, and besides a black, red-bordered spot of the tail. Nicaragua.

Th. orios Godm. & Salv. (157 b) has likewise resemblances to the *keila*-group, but beneath it resembles also *iopas* and *galliena* (157 f) by the postdiscal lines of the hindwings being placed very near to the border. Above blue with a broad black apex in which the rather large scent-spot is situate; the costal margin likewise rather broad brownish-grey. The anal angle somewhat produced, the tails only indicated. Beneath reddish brownish-grey. Guatemala.

83. Coelicolor-Group.

Th. coelicolor Btlr. (= *hena* Hew.) (157 b). The upper surface of the ♂ is sky-blue, with a broad black *coelicolor*, apex, in the anal lobe a small red spot. The ♀ is dull slate-blue with a lilac lustre. Beneath greyish-brown with white, straight postdiscal lines, on the forewing below the lower median vein displaced inwardly, on the hindwing near the proximal margin forming a very high W; before the border a brownish line, being proximally sharply, distally broadly and fadedly bordered by white; 2 red anal spots, white discal stripes are particularly in the ♀ well developed, or they are absent. From Nicaragua to Panama.

Th. pactya Hew. (157 b) greatly approximates the preceding; it is above more lustrous blue, beneath *pactya*, on the hindwings the postdiscal line is displaced somewhat inwardly below the lower radial vein, its dark bordering is proximally somewhat dusted in orange-red, the submarginal lunular line is much finer and bordered more by a brownish white. Ecuador, Colombia, Bolivia.

Th. peona Hew. (157 b) is above likewise similar, but it has a small dark discal spot, beneath almost *peona*, like *coelicolor*, the postdiscal running quite straight. Bolivia.

Th. cleocha Hew. (157 b) resembles the preceding above, but it also exhibits a likeness to the *cleon-* *cleocha*, group (p. 804, t. 159 d, e); the sky-blue is not so bright; the postdiscal line of the hindwing which is displaced inwardly on the hindwing below the lower radial vein like in *pactya*, is proximally bordered by black, then very broadly by orange-brown. Colombia.

- endela*. **Th. endela** Hew. (157 b) is above much more violettish-blue, the distal margin and apex duller blackish-brown; the under surface is browner, the postdisca line of the hindwings not so rectilinear, but more irregularly broken, between two veins always displaced once distally, once proximally. Colombia, Venezuela.
- epopea*. **Th. epopea** Hew. (157 c). The upper surface is dull lustrous ultramarine-blue with a broad black apex, in the ♀ much duller. The under surface is brown, at the proximal margin of the forewing white, the lines intensely white, the proximal line about in the centre, the distal one consisting of separated, white, distally black-bordered, small spots; towards the margin a third row of small, round, white spots, on the forewing much more indistinct, the red anal spots are very large, connected by a red bridge. Ecuador, Colombia.
- upupa*. **Th. upupa** Drc. (157 c) is above of a purer and deeper blue than the preceding, of a broader, rounder shape of the wings, the apex of the forewing broader black; on the under surface the postdisca line of the hindwing runs more obliquely and is displaced far inwards below the lower median vein, on the hindwing it is quite irregularly broken; at the rise of the lower median vein there is another isolated, drop-shaped, white spot; the red anal spots are not connected. Costa Rica to Colombia (Rio Aguaca Valley in Coll. FASSL).
- epopeoides*. **Th. epopeoides** Schs. is above at the proximal margin and in the basal half dull metallic blue with a broadly black apex, the hindwings finely bordered by black. On the grey under surface the postdisca line of the forewing extends only as far as the lower median vein, on the hindwings it runs in a straight line from the costal margin to the lower median; the antemarginal line consists of fine, white, separate, small lunular spots which are distally bordered by black. Expanse of wings: 20 mm. Mexico.
- picus*. **Th. picus** Drc. (157 c) is somewhat larger than *upupa*, above dull violettish-blue with a white line before the fringes of the hindwing near the anal angle. Beneath it likewise greatly resembles the said species, but it is easily discernible by the very extensive white dusting at the distal margin of the hindwings which exhibit besides a small red spot at the costal angle. Brit. Guiana, Brazil (São Paulo, Sa. Catharina).
- aholiba*. **Th. aholiba** Hew. (= *aritides* Schs.) (157 c) is separated from the preceding species by the large brown scent-spot which the cell of the forewing exhibits within the very broad blackish-brown apical colour; only the small basal half of the proximal margin is violettish blue like the disc of the hindwing. Beneath the wings are deep purple-brown, in the distal-marginal area of the forewing lighter brown; the lines are similarly arranged as in *coelicolor*, of a bright light-blue; on the hindwings the postdisca line is outwardly displaced between the radial veins; the red spots are connected by a bridge. Colombia, Venezuela.
- alihoba*. **Th. alihoba** Stgr. (157 d) from Bolivia is presumably a good species; the co-types lying before me exhibit above a somewhat dull milky blue; beneath on the hindwings the postdisca line runs more uniformly, between it and the submarginal line there is a broad stripe of bluish-white dusting, all the lines are more pronounced.
- aphaca*. **Th. aphaca** Hew. (157 d) we range here owing to its very similar marking beneath. The ♂ is above violettish-blue with a roundish, brownish-grey scent-spot behind the cell-end and a narrow blackish-grey margin; the anal lobe is very much stretched forward inwardly, exhibiting a small black spot, and before its fringes for a short distance a white line. The ♀ is tinged in a very dull lilac-blue, outside broad brownish-grey. The under surface is brownish-grey, in the ♀ lighter with similarly arranged lines as in *coelicolor*, but they are broader white, the proximal submarginal line of the hindwing is removed more towards the base at the costal margin and the discal side of the W does not touch this submarginal line. Brazil (Rio Grande do Sul).
- phacana*. **Th. phacana** sp. nov. (157 d) is a very closely allied species. The ♀ is above light greenish-blue, broadly margined by blackish-brownish, on the hindwings analwards with 3 or 4 small blackish spots behind the whitish marginal line. Beneath almost the same colours and markings, but the two submarginal lines of the hindwings are much clearer and more remote from each other, the space between the red spot of the tail and the black spot of the anal lobe likewise exhibits an orange-red spot being beneath pupilled in black. The shape of the wings is much rounder. 2 ♀♀ from Colombia (Rio Negro and Aguaca Valley).
- gaina*. **Th. gaina** Hew. (157 d) is easily to be united with this group. Above dull greyish-brown, towards the base with a somewhat greyish-blue tinge. Hindwings before the black marginal line with a white line, particularly distinct towards the anal part and some small blackish spots. The under surface likewise entirely resembles that of *coelicolor* (157 b), but the space behind the proximal submarginal line is filled up by an orange-red band as far as the costal margin. The large spot of the tail situate in it exhibits a black triangular spot. Ecuador, Bolivia.
- teatea*. **Th. teatea** Hew. (157 d) greatly approximates the preceding; above of a delicate light-blue in the disc with a somewhat diaphanous marking beneath, which is just like in *gaina*, but the white postdisca bands are twice or thrice as broad and the orange band is not so extensive. Colombia, Amazon.
- japola*. **Th. japola** Jones (157 h) is allied to *gaina*, but above dull steel-blue, distally broad greyish-black; hindwings at the anal lobe with a red spot. Beneath just like there, the white lines proximally with a broader red-brown tinge, the orange-red band of the hindwing is absent, only the 2 orange anal spots are present. Described from Castro (Paraná).

84. *Odinus*-Group.

Th. odinus *Godm. & Salv.* (157 e) is undoubtedly closely allied to *aholiba* (157 d). Above lustrous *odinus*, sky-blue, broadly margined in brownish-black with a blue submarginal line in the anal part of the hindwing. Beneath the forewings are marked as in *aholiba*, only the postdiscal line is more undulate and in the light inner-marginal area beneath the lower median vein it turns back with a distally open, obtuse angle. The hindwings are likewise alike, but more irregularly marked, the light-blue lines thicker and more luminous; at the costal angle of the hindwing there is often some red-brown dusting. Panama to Colombia.

85. *Corolena*-Group.

Th. corolena *Hew.* (152 k) is above deep violet, with a broad black apex and distal margin and a *corolena*, small light-grey scent-spot in the cell. Beneath deep purple-brown, the forewings unmarked, the hindwings with the postdiscal and submarginal lines being brought very near to each other and very near to the border; the former consisting of white, proximally black, small streak-spots, the latter of dark lunae bordered on both sides by white dusting. Abdomen beneath yellowish white. Guiana.

Th. viola *sp. nov.* (157 e) is very similar, above deep purple-violet, so that the dark apex scarcely *viola*, contrasts with it, differing by a very large double scent-spot, the proximal portion at the cell-end deep blackish-brown, the distal part greenish slate-grey; in the anal lobe a large red spot. Beneath similarly greasy lustrous lilac-brownish-grey, marked just the same on the hindwings, but with a much smaller red spot of the tail and also on the forewings a postdiscal line forming an angle inward below the lower median vein in the lighter grey inner-marginal area. Abdomen beneath white. Amazon.

Th. guapila *Schs.* (157 e) differs above by a much purer metallic blue, a considerably smaller scent-spot *guapila*, the proximal part of which is small, black, the distal part being oval and brownish; in the anal lobe no red. Beneath slate-grey, on the forewings the postdiscal line extends only as far as the lower median vein, on the hindwings it is displaced more inward, otherwise of the same shape. Abdomen beneath yellowish-white. Costa Rica.

86. *Galliena*-Group.

Th. galliena *Hew.* (157 e) is above deep indigo-blue with moderately broad black margins and a red *galliena*, anal spot of the hindwing. Beneath dark red-brown, the postdiscal lines placed near the border, darker brown, with a fine, white, distal tinge, on the forewings, however, but very little; the submarginal line less distinct, darker brown; between the tails a deep red spot pupilled in black; between it and the black anal spot a white-dusted spot. Distinguished from the species of the preceding group merely by the absence of the scent-spot. Nicaragua to Brazil.

Th. nisaee *Godm. & Salv.* (154 e) is very similar, but above violettish purple-blue, beneath the sub- *nisaee*, marginal line of the hindwing has a whitish tinge analwards. Panama to Colombia and Bolivia.

Th. lophis *Drc.* (157 e) differs from *nisaee* by a more metallic, purer blue and a more broadly black *lophis*, apex of the forewing. Beneath easily recognizable by an orange-red spot at the costal base of the forewing. Expanse of wings: 35 mm. Colombia.

87. *Orcidia*-Group.

Th. orcidia *Hew.* (157 f). Above dull indigo-blue with a narrow black margin and a small red anal *orcidia*, spot, beneath light brown, the base, the proximal margin of the hindwing, and two broad postdiscal bands dark-brown. On both wings are indistinct double cell-end-streaks; the postdiscals are situate at the proximal edge of the brown bands, copper-red, on both sides bordered by black and on the hindwings distally yet by white; at the border are darker submarginal lunae and spots, at the anal angle 2 narrow red crescents. The width of the red postdiscal varies, it may also be absent altogether. Occurring from Mexico to Brazil.

Th. myrsina *Hew.* (157 f) is above just the same, beneath the basal spot is more sharply defined, the *myrsina*, postdiscal lies on the forewings outside the brown median band, on the hindwings inside, without the red bordering; on the forewing it is displaced far inward below the lower median vein. Nicaragua to Colombia.

Th. tabena *Godm. & Salv.* (157 f) looks beneath like *myrsina*, but above it is one-coloured brown, *tabena*, From Mexico and Guatemala.

Th. tarpa *Godm. & Salv.* (157 e) resembles *tabena* and is above brown like it, but it is considerably *tarpa*, smaller and has beneath a white discal line, also the distal margin of the forewing is whitish. Mexico.

Th. taminella *Schs.* is above one-coloured brown with an orange anal spot, beneath very much like *taminella*, *tabena*, the light band yellowish-white, the brown band behind it distally bordered by white, on the forewings

straight, on the hindwings on the lower radial vein broken, from here proximally bordered by black. Expanse of wings: 20 mm. Castro (Paraná).

canacha. **Th. canacha** Hew. (157 f) resembles *tabena* above, the ♂ is brown, the ♀ on the hindwings blue-tinged; beneath likewise very similar, the brown band on the forewing very narrow, easily recognizable by the double rows of small arcuate spots before the distal margin of the hindwing; the postdiscal lines are proximally tinged by an orange brownish. Venezuela, Colombia.

arza. **Th. arza** Hew. (157 f) is above likewise brown like the preceding, the ground-colour beneath, however, is yellowish-white, with which the broad brown bands and the basal area are sharply contrasting; in the hindwings the white, dark-tinged postdiscal line penetrates analwards into the brown band. Mexico to Panama.

paralus. **Th. paralus** Godm. & Salv. (157 f) greatly approximates *arza*, but it is smaller, and the ground-colour beneath more a dirty grey, the dark bands are removed more inward, more faded. Guatemala, Costa Rica.

calatia. **Th. calatia** Hew. (157 f) deviates from the preceding by its orange-yellow under surface; the white postdiscal line traverses the brown band on both wings; the distal margin remains one-coloured yellow. Guatemala, Nicaragua.

aunus. **Th. aunus** Cr. (157 f) we add yet to this group, though it deviates greatly. Above indigo-blue. The under surface is yellowish-white, towards the margin warming into lilac-brown; the base of both wings and a large triangular spot at the costal margin of the forewing are brown; the hindwings exhibit a double, brown discal streak, the postdiscal line is strongly broken and makes a bend inward on the forewing below the lower radial vein; small orange anal spots are merely indicated. Guiana to Brazil.

duma. **Th. duma** Hew. (157 g). We here append this quite isolated animal. Above dark-brown, with a blue tinge, beneath yellowish-white, large median spots, broad postdiscal bands, and the distal margin brown. Bogotá.

88. Maeonis-Group.

maeonis. **Th. maeonis** Godm. & Salv. (157 g) is above light-blue with a broad black apex, beneath rusty-brown and distinguished by the postdiscal being moved as far as into the middle of the wing; the lines are white, the proximal line inside, the distal one outside bordered by red-brown, at the anal angle of the hindwing by black; the anal lobe and spot of the tail black, proximally bordered by a broad red-brown, between them a black spot being inside dusted in white. Mexico, Guatemala.

89. Tema-Group.

tema. **Th. tema** Hew. (157 g). Above dark-brown, the forewing at the proximal margin and the hindwing in the disc dusted in blue. The under surface is chocolate-brown, each of the wings with 2 white transverse lines in the middle and behind it, on the forewings straight, on the hindwings broken and dentate; each wing besides with 2 indistinct, white, antemarginal lines. The hindwings have two fine tails, above them and at the anal angle the usual, small red spots. Amazon.

paron. **Th. paron** Godm. & Salv. (157 g, h) on the whole resembles the preceding, but it has only one tail and the under surface is more greenish black instead of brown. Guatemala.

heraclides. **Th. heraclides** Godm. & Salv. (157 g) greatly resembles *paron*, but above it is metallic bluish-green, with a large, dark discal spot, behind which the wings exhibit a black reflection; the shape of the wings is a little more obtuse. Costa Rica.

sergius. **Th. sergius** Godm. & Salv. is above almost the same, but the discal spot is of a radiant blue, the black distal margin broader. This species and the preceding exhibit also a resemblance to the *trochus*- and *ronos*-group (p. 756), but they greatly deviate by the tails and the scent-spots.

dodava. **Th. dodava** Hew. (157 g) we include in this group. It is above lilac with a large, black discal spot behind the cell; beneath grey with whitish discal streaks and dentate lines, in the ♂ the proximal margin of the forewing is blue. Panama.

nora. **Th. nora** Jones (157 g) is very closely allied, larger, more slender, more purple-violet, the distal margin and apex only narrowly black, the scent-spot is the same. The under surface is more blackish, the white transverse lines are more subdued, on the hindwings proximally bordered by orange, more strongly broken, above the upper median vein displaced outward, between the orange anal spot a black, white-strewn spot. Brazil (Castro; Amazon).

aepea. **Th. aepea** (157 g, h) is a small, above dull ultramarine-blue species with broad blackish-grey margins; the ♀ is duller and lighter blue, the hindwings almost entirely brownish-grey. Beneath light-grey, with clear

and sharp markings: 2 postdiscal lines on each wing, the proximal one tinged inside in brownish, the distal one outside, the proximal line on the forewing straight, on the hindwing dentately broken, the distal ones on both wings more crescentiform. Ecuador, Peru, Bolivia.

Th. muatta *Hew.* (157 h) may be inserted here. Above dull indigo-blue with broad blackish-grey margins and a fine white marginal line before the fringes of the hindwing. Beneath grey with an oblique white postdiscal line on the forewings, which makes an acute angle inward below the lower median vein and is proximally bordered by dark-grey; on the hindwings it is broken and forms a W at the proximal margin; the submarginal line consists of small brownish spots, on which we notice inside whitish crescents; 2 orange anal spots. Brazil.

Th. muattina *Schs.* differs from the preceding only by orange fringes of the forewing and an orange anal spot above. Castro (Paraná).

Th. aepeona *sp. nov.* (157 h). Very near to *aepea*, larger, above more lustrous blue with a narrow black distal margin, only the apex is a little broader black. Beneath the forewings are marked about the same, on a lighter grey ground, on the hindwings, however, the postdiscal line begins in the middle of the costal margin and runs straight to the lower median vein, in order to form a W then; the submarginal lines are more apart from each other. Peru, Colombia.

Th. renidens *sp. nov.* (157 h) greatly approximates the preceding; it is above lustrous ultramarine-blue; the very broad blackish-brown apex runs in almost the same width close behind the cell as far as the lower median vein, then on the latter along to the very narrow black distal margin, its proximal bordering exhibits an intense violet lustre; the cell, on being exposed to an oblique light, is covered with indigo-blue scales. The under surface likewise resembles the preceding, the ground-colour is just a little more brownish; on the forewings the space between the submarginal lines, particularly towards the proximal margin, is filled up by orange-brownish; on the hindwings the proximal submarginal line is more irregularly broken, between the subcostal vein and the upper radial it protrudes more inwardly. Peru (Marcapata), Bolivia.

Th. mimula *sp. nov.* (157 g) differs by its smaller size and above by its plainly brown ground-colouring; the fringes of the hindwing at the base white, distally black, close behind there is a black marginal line being proximally bordered again by white. Beneath also very much like the preceding, pale olive-brownish grey; on the forewings the postdiscal line is situate close behind the cell and extends only to the lower median vein, the proximal submarginal line is removed far inward, the distal one being sharply separated from the white marginal line by an olive-brownish line. Hindwings marked about as in the preceding, but the distal margin, particularly within the scope of the orange spots, is extensively white. Pachitea (Peru).

90. Thespia-Group.

Th. bosora *Hew.* (157 k) forms the transition from the preceding group to this group. Above dull blue, the apex and distal margin of the forewings broadly brown-black, in the disc a large, brilliant, ultramarine-blue scent-spot; the marginal line of the hindwings black, proximally white; fringes likewise white, bordered by black. Beneath brown with clear, light-blue, undulate, on the hindwings broken transverse lines and discal streaks; on the forewings the postdiscal is proximally delimited below the lower median vein and runs very obliquely towards the whitish anal angle. In the anal part and at the costal angle of the hindwings there are red-brown spots. Ecuador to the Amazon.

Th. thespia *Hew.* (157) is above magnificently *Morpho*-blue with a narrow black apex, beneath peculiarly greyish-green with about the same linear markings as *bosora*, but the white discal streaks are absent; also here a red spot is situate at the costal angle. The ♀ is above dull-blue, very broadly bordered by greyish-black, beneath lighter, the red spots at the anal angle broadly flown together. Ecuador, Amazon.

Th. photismos *Drc.* (157 h) is allied to the preceding; above brilliantly bright sky-blue, with a moderately broad black-brown margin. Under surface greenish-grey with the same linear markings as the preceding, but without the red spot of the costal angle and with broadly flown together, red spots at the anal angle of the hindwing. Ecuador (Sarayaçu).

Th. margarita *sp. nov.* (157 i) is another similar species, above at once to be distinguished by the peculiarly mother-of-pearl green colour, exactly as in *margaritacea* (153 b), with a but extremely fine black marginal line and black, on the hindwings proximally white fringes. Beneath almost like *thespia*, without the costal-angular spot of the hindwing, the postdiscal line of which runs from the middle of the costal margin almost straight through to the W. Bolivia (Rio Songo).

Th. azurinus *Btlr.* (157 i) we append here, although there are no closer affinities on account of the similar under surface. Above blue with a red-brown, oval scent-spot and a broadly black apex; beneath greyish-green with similar linear markings as the preceding, but on the forewings only 2; they are less undulate and are, particularly on the hindwings, situate nearer to the border. Costa Rica.

91. *Critola*-Group.

critola. **Th. critola** Hew. (157 i) is an entirely isolated animal. Above lustrous ultramarine-blue with narrow black margins and a large black scent-spot. Beneath grey with brown transverse dashes, behind them on the forewings with a rusty-brown band and on the hindwings a chain of light-yellow small spots bordered distally by brown; the two small anal spots are yellow bordered above by brown. Mexico.

92. *Hesperitis*-Group.

hesperitis. **Th. hesperitis** Btlr. (= *cabiria* Hew., *perdistincta* Kaye) (157 i) is above black-brown, only on the hindwings beginning from the lower radial vein towards the proximal margin there is a blue sprinkling with a red spot in the anal lobe. Beneath brown, at the proximal margin of the forewing a little lighter; on the forewings an almost straight, darker brown, distally somewhat lighter tinged postdiscal line as far as the lower median vein, before the border an indistinct, darker line. On the hindwings the postdiscal line begins with a small spot being a little distally inclined; this line is black with a distal white tinge and, towards the proximal margin, proximally sometimes strewn with orange; the angle of the W, resting on the lower median vein does not reach so far towards the margin as the anal one; anal spot black, the spot of the tail copper-red with a black triangle in it, between both white dusting on a black ground. — In more southern specimens, = **lugubris** Mschlr., the spot of the tail is more brown. Most widely distributed from Mexico to Brazil.

aruma. **Th. aruma** Hew. (157 i) looks very much like the following above, but it differs by the broader black distal margin of the hindwings. Beneath it is marked like the preceding; the red colour at the anal spots is either absent altogether or it is just as extensive as in *hesperitis*. Guiana to Brazil.

camissa. **Th. camissa** Hew. (= *vespasianus* Btlr., *chariclorus* Btlr.) (157 k) is above magnificently ultramarine-blue with a violet lustre, the apex broadly black, on the median projecting pointedly towards the base. Distal margin narrowly black, the costal area of the hindwing broadly black. The under surface olive-yellowish, lustrous; marked as in *hesperitis*, the red spot of the tail reaches as far as or almost as far as the discal side of the W. Guatemala to Peru.

simasca. **Th. simasca** sp. nov. (157 k) differs from the preceding above by the increased blue colour being situated only below the lower median vein, the inner-marginal vein remains broadly black; on the hindwings there are only towards the anal angle some violet scales. Beneath there is no difference. Colombia (Rio Negro).

gedrosia. **Th. gedrosia** Hew. (157 k) is above blackish-brown, both wings towards the base with a deep violet-blue tinge. Beneath dark-brown, marked as *hesperitis*, the black of the postdiscal line more intense, the W more uniform, distinguished by the very large, red anal spots; in the surroundings of the spot of the tail there is on both sides extensive whitish dusting. Amazon.

devia. **Th. devia** Mschlr. seems to be very closely allied to the following. On the upper surface the forewings are blackish-blue, the hindwings lighter blue. The ground-colour beneath is grey-brown, the marking as in *xeneta*, the 2 red-yellow anal spots distinct. Length of forewings: 13 mm. Surinam.

xeneta. **Th. xeneta** Hew. (157 k) is above dull greenish indigo-blue, the forewings towards the margin with a bright ultramarine-blue reflection; the under surface is sooty blackish-brown, with the same markings which are distally somewhat lighter tinged and grow somewhat more purely white only within the scope of the W; in the northern, mostly a little lighter specimens some deep red-brown becomes visible at the anal angle, disappearing entirely in the sooty-black area in more southern specimens. From Guatemala to South Brazil.

partunda. **Th. partunda** Hew. (= *origo* Godm. & Salv.) (157 k) is of a deeper, more intense blackish-brown, on the hindwings the metallic-blue spot extends close to the base. The under surface is lighter, the anal spots with a broad red margin. Panama to the Amazon.

vitruvia. **Th. vitruvia** Hew. (157 c) seems hitherto to be known typically in but one specimen. Forewings black, at the proximal margin broadly ultramarine-blue, hindwings not metallic blue, at the distal margin broadly blackish-brown like at the costal margin. Beneath like the preceding, but the spot of the tail is not red, but dark-brown. The type originates from Para. — **fortuna** Drc. is above and beneath the same, but the spot of the tail is bordered by red. Peru, Amazon. — **torqueor** Drc. is above somewhat lighter blue, this colour on the forewing reduced, beneath like *fortuna*. From Brit. Guiana. — **indigo** Drc. has above on the forewings only a narrow blue stripe at the proximal margin and is beneath coloured as *vitruvia*; this form from Brazil is considerably smaller. — **anfracta** Drc. has above one-coloured greenish-black forewings, for the rest like the type. Described from Peru.

thama. **Th. thama** Hew. (158 a) is smaller and above very lustrous metallic-blue, more greenish than *xeneta*, the costal margin of all the wings very broad, the distal margin narrowly black. Beneath somewhat lighter than the said species, about as *partunda* with bright red spots, also the W is beneath filled up with red and proximally bordered the same. Panama to Colombia.

Th. atrox *Btlr.* is above smoky-brown with a purple reflection, beneath grey-brown with a cell-end- *atrox*, streak and very similarly marked to *thama* (158 a), the W beneath filled up with red, but proximally not bordered by red. Guiana to the Amazon.

Th. capeta *Hew.* (158 a) we include here owing to the under surface being marked the same. Above *capeta*, duller blackish-brown, the hindwings exhibit in the proximal-marginal half towards the margin a large, lilac-blue spot, in the anal lobe a small red spot. Beneath exactly as *hesperitis* (157 i), only of a somewhat more lustrous, olive-yellowish tinge. Nicaragua, Colombia.

Th. netesca *sp. nov.* (158 a) greatly approximates *xeneta* (157 k), but above on both wings it is dull *netesca*, steel-blue, with narrow blackish-brown margins. Beneath slightly lighter blackish-brown, the postdiscal line on the hindwing more irregularly broken, the submarginal lines much nearer to the margin, the small anal spots bordered by deep red-brown. Guiana to South Peru.

Th. vesper *Drc.* (158 a) is above deep metallic blue with rather broad black margins and behind the *vesper*, cell of the forewing a black spot being connected with the costal margin; in some specimens the cell itself is also black. Beneath very similarly marked to *thama*, but the ground-colour is a light ashy grey; on the hindwings the postdiscal line is more angularly broken, not with such pointed angles as there; the anal spots are lighter orange. Peru and Bolivia.

Th. zurkvitzi *Schs.* may yet be appended here. Above quite brown with a red anal spot of the hindwing *zurkvitzi*, and a white marginal line analwards. Beneath lighter brown with a blackish marginal line; the postdiscal line on the forewing is reddish-brown, distally black, then white-bordered, beneath the lower median vein displaced inward, on the hindwings proximally brighter and broader red, running as in *hesperitis* (157 i); the submarginal lunae darker brownish, on the hindwings bordered by whitish; the anal spots large, red; also above the spot of the tail some red. Expanse of wings: 25 mm. São Paulo.

93. Centoripa-Group.

Th. centoripa *Hew.* (= *hahneli* *Stgr.*) (158 a) looks above almost like *xeneta* (157 k), but the hindwings *centoripa*, are more extensively blue. Beneath similarly blackish-brown, but very peculiarly marked: the postdiscal line on the hindwing placed quite into the centre, beginning at the costal margin with a large black spot and containing the light discal streak in the middle of it; the W at the proximal angle distally bordered by white; the anal spots in the darkened distal margin are black. Colombia, Peru, Amazon.

94. Cecrops-Group (*Calycopis* *Scudd.*).

Th. cecrops *F.* (= *poeas* *Hbn.*, *beon* *Godt.*) (158 b) is the northern representative of a difficultly *cecrops*, separable group of small species of which a very great number is described that are surely partly coincident as synonyms. The present species is either above quite dark-brown, or on the forewings towards the base and on the hindwings in the inner-marginal half suffused with blue, in the ♀ more intensely. The hindwings exhibit towards the proximal angle a fine black marginal line being proximally bordered by blue-white, and a small red anal spot. The under surface is light-brown, the costal base of the forewing orange; both wings exhibit fine, double, orange-red discal streaks, on the hindwings more distinct, both with broad, orange-red discal bands on the forewings almost straight as far as the lower median vein, on the hindwings straight as far as the lower radial vein, then broken and forming a W at the proximal angle, distally finely tinged in black, then white. Distally follows the subterminal formed of blackish crescents, between the lower radial and the lower median vein more intensely black, placed nearer to the postdiscal line, distally filled up with 2 orange crescents which exhibit towards the margin high black triangular spots; then follows analwards a black spot densely strewn with blue-white; the anal lobe itself is above bordered first by white, then by orange; a fine black marginal line, proximally tinged in white. Everywhere common in the Southern States, West Virginia, Kentucky and Indiana. — **beon** *Cr.* (= *isobea* *Btlr.*, *bactra* *Hew.*, *caulonia* *Hew.*, *vibulena* *Hew.*, *belleria* *Hew.*, *jeneirica* *Fldr.*) *beon*, (158 b) is distributed in the whole of Central and South America to South East Brazil and mostly common. This form is above deeper blackish-brown, the hindwings in the ♂ more extensively and more metallic blue in a rather variable extent; in the ♀ the blue is mostly duller and lighter and is to be found also on the basal inner-marginal half of the forewing. The ground-colour beneath is generally darker brown, the postdiscal lines very much narrower red and much deeper, almost scarlet-red, the black filling up of the two red spots of the tail is much more reduced and does not reach as far as the marginal line, the space between them and the anal spot is not so extensive and not so blue, but more strewn with greyish-white.

Th. amplia *Hew.* (158 b) is above very similar, the blue is particularly in the ♀ somewhat more whitish, *amplia*, not so ultramarine-blue; beneath darker brown, on the forewings the proximal orange bordering of the post-discal line is absent, on the hindwings the orange marginal lunae are proximally bright ochreous yellow or

straw-coloured, the one above the upper median vein is but slightly indicated, its black pupil is absent. Guatemala, Nicaragua, Colombia, Guiana.

- nortia*. **Th. nortia** *Godm. & Salv.* (158 b). Both sexes are above more extensively and more deeply blue than *beon*, in the anal lobe is a small red spot. The under surface is more grey, the postdiscal line only towards the proximal angle of the hindwing proximally bordered by red-yellow, the submarginal lines are on both sides more distinctly bordered by white. From Guatemala.
- guzanta*. **Th. guzanta** *Schs.* is above brown, with a red anal spot of the hindwing; beneath the postdiscal lines are so broadly tinged in red as in *cecrops* (158 b), particularly on the hindwings; the cell-endstreak is only a light streak, not red and double; the moonspotted submarginal line is distally tinged in red which grows more intense between the median veins and is black-pupilled. Expanse of wings: 22 mm. Mexico (Jalapa).
- geminata*. **Th. geminata** *sp. nov.* (158 b) is very much like the preceding and distinguished by very intense, double, red discal streaks beneath; the submarginal line is distally dusted in orange also on the forewings, on the hindwings very broad and forms a continuous red band from the costal angle to the anal lobe. Rio Songo (Bolivia).
- suda*. **Th. suda** *sp. nov.* (158 b) is beneath scarcely different, the tinge is a little more olive, on the forewing there is a red-yellow marginal line, also on the hindwing it is somewhat red-yellow at the ends of the veins and the base of the fringes; above the forewings are black, at the proximal margin a metallic blue stripe; the hindwings are metallic sky-blue, at the distal margin and costal margin narrowly black, before the black marginal line with narrow, black, small spots. Rio Songo (Bolivia).
- lorina*. **Th. lorina** *Hew.* (158 c). Of this pretty species only 2 ♀♀ seem to have become known hitherto. Above dark-brown, both wings towards the base sky-blue. Beneath grey with similar markings as the preceding, but on the forewing the postdiscal line is regularly undulate and running through as far as the proximal margin, making a deep bow inward below the lower median vein; there is no discal streak at all; on the hindwing the submarginal line is red-brown, on both sides bordered by white; the two red spots of the tail and the anal spot are connected by a red bridge. Probably from Venezuela.
- cyanus*. **Th. cyanus** *sp. nov.* (158 c) is above brilliant light-blue with a broad black costal and distal margin, the hindwings are quite narrowly bordered by black, only at the apex a little broader; between the tails, before the border, a black dot; beneath hardly different from *suda*, only of a somewhat lighter and more yellowish tinge. Bolivia.
- talama*. **Th. talama** *Schs.* is quite a little species which may belong here. Forewings black, hindwings of a dark-blue tinge with a white marginal line analwards. Beneath light greyish-brown with dark, distally light-bordered cellular streaks; the postdiscal line dark-brown, distally whitish, on the hindwings proximally dark-red; darker brown submarginal shades are proximally bordered by whitish; the spot of the tail red with a little black pupil close at the border, and some red above the upper median vein. Expanse of wings: 17 mm. Petropolis in South Brazil.
- hosmeri*. **Th. hosmeri** *Weeks* is very incompletely described, but it may belong here. Above black with a slate-coloured reflection. Beneath brownish slate-coloured; the postdiscal lines red, distally white; the anal spot and two spots of the tail red. Expanse of wings: 23 mm. Venezuela (Suapure).

95. Endymion-Group.

- endymion*. **Th. endymion** *Cr.* (= *tyrtacus F.*, *xenophon Don.*, *hugon Godt.*) (158 c) is easily recognizable by the orange-ochreous colouring of the upper surface, only the costal margin of the forewings is broader dark-brown, the distal margin very narrow; the black marginal line of the hindwings is towards the proximal angle proximally bordered by white. Beneath brownish-grey, in the inner-marginal area of the forewing with an orange reflection with similar, but somewhat less broken postdiscal lines than in *beon* (158 b); the submarginal line carried out on both wings is a somewhat undulate brown line turning black analwards on the hindwings and being distally tinged in a broad orange as far as the lower radial vein. Colombia.
- cyphara*. **Th. cyphara** *Hew.* (158 c) is above very similar, but the costal part of the forewings almost as far as down to the lower median vein is brown, not so sharply defined as in *endymion*, but gradually warming into the orange. Beneath, the basal part of the wings as far as the postdiscal lines is somewhat darker brownish-grey than the marginal part; the spot of the tail is higher, broader red, with a thicker black pupil, the anal spot is also thicker black, the space between both not spanned by red. From Mexico to Venezuela, nowhere common.
- denarius*. **Th. denarius** *Btlr.* (= *calena Hew.*) (158 c) is likewise not dissimilar, but the orange colour is confined to the area between the median veins of the forewing; hindwings quite brown with a small orange anal spot. Beneath almost the same as *cyphara*, only darker, the postdiscal band less bordered by orange. Mexico to Panama.
- Th. sethon** *Godm. & Salv.* (158 c) is closely allied to the preceding, but the orange-copper spot is absent altogether, the costal margin of the forewing is rather darkened; the under surface is more red-brown, the postdiscal line more distinctly proximally bordered by red. Mexico to Costa Rica.

Th. plusios *Godm. & Salv.* is a somewhat doubtful species which neither fits entirely to *denarius*, nor *plusios*, to *sethon* (158 c); it differs from the former by its more red-brown wings and not darkened discal area. Mexico to Panama.

Th. perisus *Drc.* (158 c) is above monotonously dull brown with a small orange anal spot of the hindwing, *perisus*, beneath much lighter brown than *denarius*, equally marked, only the postdiscal band of the forewing is parallel to the distal margin, in *denarius* somewhat obliquely placed to it. Venezuela.

Th. joya *Dogn.* (= *callao Drc.*) (158 c) is above dark copper-brown, with a brown costal margin, *joya*, apex and distal margin, on the hindwings towards the proximal margin densely yellowish-haired. Beneath dark brown-grey, in the basal part, especially of the hindwing, darker than outside; the postdiscal lines rusty brown, distally tinged light-grey, the submarginal line composed of light-grey crescents, otherwise like *cyphara*. Peru.

Th. rugatus *Drc.* (158 d) greatly approximates *denarius* and *sethon*. Above dull olive-brown, the *rugatus*, hindwing towards the proximal margin with copper-coloured hair and a small orange anal spot. Beneath uniformly light olive-brown, the postdiscal line almost straight, broad dark-orange, distally bordered by black, then sharply by white; small, submarginal, dark nebulous spots, the spot of the tail large and of a brilliant orange. Abdomen beneath white. The ♀ is above and beneath lighter. Peru.

Th. nubilum *Drc.* is closely allied to *sethon* (158 c). Above blackish-brown with a small orange anal *nubilum*, spot. Beneath greyer, the postdiscal lines narrower, straighter and nearer to the distal margin. Castro (Paraná).

Th. fernanda *Jones* is above just the same, beneath yellowish grey-brown, the postdiscal line on the *fernanda*, forewing straighter, on the hindwing less sharply angled with a distally displaced costal-marginal spot; there are no discal streaks. Expanse of wings: 29 mm. Paraná.

Th. tirrhaea *Mschlr.* is unknown to me; size of *acaciae* (Vol. I, t. 73 b), hindwings rather long-stretched; *tirrhaea*, above plainly dark-brown, beneath lighter brown; the postdiscal line on the forewing straight, dark-brown, on the hindwing more dissolved into spots, towards the proximal margin angularly broken and distally bordered by white; double, darker brown, small submarginal spots; the spot of the tail large, oval, black, proximally edged by red-yellow, distally by white, between it and the black anal spot white dusting. Length of forewings: 13,9 mm. Surinam.

96. *Clarina*-Group.

Th. clarina *Hew.* (158 d) is above blackish-brown, at the costal margin of the hindwing brilliant *Morpho-clarina*, blue. Beneath reddish-brown, the postdiscal line is almost straightly carried through as far as the W and on the hindwing on both sides bordered by orange; the anal lobe with a small black spot, the spot of the tail orange, pupilled in black. Mexico to Panama.

Th. tamos *Godm. & Salv.* (158 d) is duller coloured, the blue which is much darker, is situate at the *tamos*, proximal margin, not at the costal margin. The under surface is very characteristic by the very much broadened postdiscal band of the hindwing, the submarginal band consists of white, distally black-bordered crescents and touches the discal side of the W on the lower median vein, it is, between the radial veins, placed nearer to the distal margin. Costa Rica, Panama.

Th. matho *Godm. & Salv.* (158 d) is not different above, beneath the white band of the hindwing is *matho*, only half as broad, the submarginal line uniformly undulate, not moonspotted. Brit. Guiana to Bolivia (Rio Songo).

Th. clarissa *sp. nov.* (158 d) we include here as the nearest ally. Above there are resemblances to *clarissa*, *tarania* (p. 810, t. 160 c, d), dull brown with a broad orange band in the anal part of the hindwing as far as beyond the lower radial vein. Beneath light-brown with white, proximally orange-bordered postdiscal lines, on the hindwings straight as far as the submedian, then in a plain, right-angled curve to the proximal margin; a broad, orange antemarginal band proximally undulately bordered by blackish. 1 ♂ from São Paulo.

97. *Calus*-Group.

Th. calus *Godt.* (158 d) is the only representative, distributed from Guatemala to the Amazon. Above *calus*, radiantly *Morpho*-blue with a very broad blackish-brown costal margin, apex and distal margin, the costal margin of the hindwing whitish, the distal margin narrowly black, only 1 tail. Beneath it is easily recognized by the triangular, dark-brown costal-marginal spot on the ochreous-brown ground. The ♀ is smaller, much duller, only in the disc of the hindwing light violet-blue, in the basal inner-marginal part of the forewing only somewhat tinged in light greenish bluish-grey.

98. *Demonassa*-Group.

Th. demonassa *Hew.* (158 d) looks above like *atrius* (158 c), beneath it reminds us of *calatia* (157 f), *demonassa*, but it has only one tail; the broad, red-brown discal bands are distally bordered by black and white lines, proximally only on the hindwing by the short cellular streak. From Mexico to the Amazon.

buphonia. **Th. buphonia** *Hew.* (158 e) is above plainly brown, beneath like the preceding, but behind the brown band of the forewing, in the anal part, there is a broad grey area, in the preceding not. Colombia, Amazon.

99. Atrius-Group.

atrius. **Th. atrius** *H.-Schäff.* (= *clitumnus* *Btlr.*) (158 e) has black forewings and radiantly ultramarine-blue hindwings with a black proximal margin and a very narrow distal margin increasing somewhat in width analwards. Beneath ochreous-brown with a faint silky lustre, marked about as the *hesperitis*-group (p. 794), but the postdiscal band of the hindwing is placed more towards the base at the costal margin. The ♀ is above dull blackish-brown, in the disc of the hindwing dark blue. From Guatemala to the Amazon, in the southern districts of the range common, to the north rarer.

mimas. **Th. mimas** *Godm. & Salv.* (158 e) is very similar, but the forewings are, from the cell to the proximal margin, likewise radiantly blue as the hindwings. From Panama to the Amazon, rare.

calor. **Th. calor** *Drc.* (158 e) is very closely allied to *atrius*, the forewings are dull greyish-brown, not black, also the hindwings much duller lilac-blue, at the costal margin whitish; nor is the proximal margin blackish-grey, but yellowish-white, like the abdomen. Beneath the same, only the discal bands are proximally broadly bordered by vermilion. Brazil.

petaurister. **Th. petaurister** *Drc.* differs from the preceding like *mimas* does from *atrius*, i. e. the inner-marginal part of the forewing is, as far as up to the cell, of the same dull blue as the hindwings. Brit. Guiana.

cos. **Th. cos** *Drc.* (158 e) has black, somewhat olive-tinged forewings and dark-blue hindwings being here, in contrast with the allies, broadly bordered in black at the costal, distal and proximal margin, and in the anal lobe a small red spot. Beneath like *atrius*. Guiana, Brazil.

100. Acis-Group.

acis. **Th. acis** *Drury* (= *mars* *F.*) (158 e) is above dark-brown, beneath very characteristic by the broad white bands of the hindwing, which meet between the median veins and are here interrupted by a large orange spot; at the base of the hindwing there are yet two tiny white spots below each other. South Florida, Antilles.

favonius. **Th. favonius** *Sm. & Abb.* (158 e) we include here owing to its external resemblance. The brown upper surface exhibits in the upper cell-end a small, oval, light scent-spot and analwards on the hindwings and between the median veins of the forewings orange spots. Beneath similarly marked as *acis*, but instead of the broad white bands there are narrow moonspot-rows. Almost the whole submarginal space is occupied by orange spots, between the spot of the tail and the anal lobe there is a long spot dusted in blue-white; the small basal spot of the hindwing may turn into a long streak. — The larva lives on oaks. Gulf-States as far as up to South Carolina.

101. Damon-Group (*Mitoura* *Scudd.*).

damon. **Th. damon** *Cr.* (= *gryneus* *Hbn.*, *damastus* *Godt.*, *smilacis* *Bsd.*, *auburniana* *Harr.*) (158 f) is above brown with an oval, brown-grey scent-spot in the upper cell-corner, the f. *discoidalis* *Skinner* has an ochreous-yellow to red-yellow disc of all the wings. Beneath green, at the proximal margin of the forewing reddish-brown, with white, on the hindwings very sinuously curved postdiscal lines, proximally broadly tinged in cinnamon-brown, and a short, similar basal transverse line; behind the white marginal line there are brown, small submarginal spots being dusted in greyish-white at the anal angle, between the median veins behind them an orange-yellow small spot being bordered above by black. — The larva lives on *Juniperus virginiana*. In 2 or 3 generations in the eastern United States.

102. Simaethis-Group.

simaethis. **Th. simaethis** *Drury* (= *sarita* *Skinner*, *lycus* *Hbn.*) (158 f) is above lustrous violet with a brown costal and distal margin, the anal lobe of the hindwing, being rather much drawn out, is rusty-brown. The ♀ is blackish-brown, towards the base with a bluish-grey tinge. The under surface is light green, in the inner-marginal part of the forewings grey with silvery white, transverse lines being proximally more broadly, distally more narrowly bordered by red-brown. The distal margin of the hindwing is, on the red-brown ground, densely dusted in white and exhibits before the anal angle 2 or 3 silvery spots. Most widely distributed from Texas to South Brazil, also in the Antilles.

moesites. **Th. moesites** *H.-Schäff.* is half as large as *simaethis*, above brighter dark-blue; beneath the red-brown postdiscal stripe is tinged white only on the hindwings in the inner-marginal part, and the whole distal part as far as to it is violetish-grey, towards the base cinnamon-brown, towards the costal margin silvery-blue with 3 black spots in the anal part. Cuba.

telea. **Th. telea** *Hew.* (158 f) is considerably smaller, above very similar, but the ♀ is more extensively and more purely blue. Beneath the silvery-white discal bands are reduced to small indistinct spots, only at the

anal angle distinct as a high W; also the red-brown colour of the distal margin is confined to the anal half, slightly dusted in white and decorated with increased silvery spots. Still farther distributed than the preceding, from Mexico to Paraguay.

Th. crethona *Hew.* (158 f) is considerably larger than *telea*, above indigo-blue with narrow black margins; *crethona*, the under surface is very similar, at the anal angle of the hindwing more extensively cherry-red, upwards bordered by the distinct, silvery W. Cuba, Jamaica.

103. Badeta-Group.

Th. badeta *Hew.* (158 f) is a species not yet sufficiently known among which there may be 2 or more *badeta*, that are closely allied. The ♂ is above dark violet-blue with a purple reflection, the costal margin and apex broader, the distal margin very narrow greyish-brown, the hindwings in 2 ♂♂ before me from the Coll. SEITZ exhibit 1 small tail. DRUCE is of the opinion that the ♂♂ are untailed and only the ♀♀ tailed; more ♂♂ seem not to be known at present. The ♀♀ are above brown, according to the original description „sometimes“ blue-tinged (= f. *melba* *Hew.*). 5 specimens before me are above all intensely blue, in the whole inner-marginal *melba*, half of the forewing and in the disc of the hindwing, only a sixth is quite brown, without any blue at all. Beneath bright light-green, the postdiscal blackish, distally white, extending on the forewing as far as the lower median vein, almost straight, on the hindwing angularly broken, at the anal angle forming a flat W. The anal spot black, above white, then orange-bordered, the spot of the tail thick orange-red, black-pupilled, between both another tiny orange spot, sometimes all the 3 spots are broadly connected. The marginal line in the anal half black, proximally white, otherwise together with the fringes reddish-brown. Guiana, Colombia, Brazil.

Th. carla *Schs.* seems to be closely allied. Above dark violet-blue with a broadly blackish-brown *carla*, apex and costal margin. Beneath brilliant green with red-brown fringes, the forewings without markings; on the hindwings the postdiscal is reddish-brown and the spot of the tail is only a small red dot; the hindwings themselves are uniformly rounded and without a tail. Expanse of wings: 19 mm. Colombia.

Th. gabina *Godm. & Salv.* (158 f) is above blackish-brown, at the base of the forewings and in the disc of *gabina*, the hindwings dull lilac-blue. Hindwings with short tails. Beneath green, forewings unmarked, at the proximal margin grey. Hindwings with a fine black, distally white postdiscal being more arcuately undulated, not acute-angularly broken. Spot of the tail small, red, black-pupilled; anal spot black, between both another small black spot; palpi and forehead green. Mexico to the Amazon.

Th. myron *Godm. & Salv.* is very similar; the hindwings, being blue in the disc, have no whitish sub- *myron*, marginal line, and beneath, the anal angle is proximally bordered by red. Costa Rica and Panama.

Th. oleris *Drc.* (158 g) differs above by brown, olive-tinged wings. On the under surface, the forewings *oleris*, are unmarked as in *gabina*, at the proximal margin grey; the hindwings exhibit a light discal streak, the postdiscal as in *gabina*, but feebler, the spot of the tail is absent altogether and at the anal angle there is a small black dot being bordered above by yellow. Palpi grey, with black hair, the terminal joint black, at the apex white; forehead brown with a small green dot between the eyes. Paraguay.

Th. lampetia *Godm. & Salv.* has above in the inner-marginal half of the fore- and hindwing a much *lampetia*, brighter blue. Beneath the transverse lines are blacker, the red submarginal spots proximally broadly bordered by black. Costa Rica.

Th. caespes *Drc.* (158 g) is allied to the preceding, above almost the same; head, collar, and costal *caespes*, base of the forewing metallic bronze-green, fringes copper-brown. Beneath dull bronze-green, marked as *lampetia*, the proximal margin of the forewing dull copper-coloured. Bolivia.

Th. aguaca *sp. nov.* (158 f) is above blackish-brown as *oleris*; beneath more bluish greyish-green, *aguaca*, the unmarked forewings at the proximal margin brownish-grey. Hindwings as in *oleris* with a light cell-end-streak and a very arcuate postdiscal being broad and distinct proximally black, distally white; at the anal angle are 3 purple-red, small spots surrounded and strewn with black, upwards bordered by light bluish; above the upper median vein and between the radial veins are at the margin yet 2 small white spots. Fringes dull bronze-green, at the anal angle white, distally black, in front of them a black, white-tinged marginal line. Forehead and palpi as in *oleris*. Colombia (Rio Aguaca Valley).

Th. crispisulcans *sp. nov.* (158 g) is very similar, above blackish-brown, towards the base with a *crispisulcans*, bluish-grey reflection. Beneath somewhat lighter, more yellowish green, the postdiscal similar, but consisting of much more curved bows, below the lower median vein and below the lower and above the upper radial veins receding very far towards the base; on the hindwing there is a complete row of bronze-brown, small submarginal spots, running through as far as the costal margin, the spots being on both sides bordered by whitish; the spot of the tail orange, black-pupilled. Sa. Catharina. Type in the Coll. WERNICKE.

nitetis. **Th. nitetis** Godm. & Salv. (158 g) we append here yet, although it belongs farther in front, owing to its habitus and scheme of markings. Above brown, in the ♀ towards the base and in the disc of the hindwing dull blue. Beneath peculiarly greyish-green; the postdiscal on the forewing little distinct, but carried out as far as the proximal margin, proximally displaced below the lower median vein and on the submedian fold proximally angularly broken; on the hindwings more strongly broken with a high W at the proximal angle, inside tinged in red-yellow; at the anal angle 3 or 4 red-yellow spots, the one between the tails black-pupilled. Mexico, Colombia, Brazil.

104. *Vesulus*-Group.

vesulus. **Th. vesulus** Cr. (158 g) is above blackish-brown with lighter fringes being on the hindwing towards the anal angle white. Beneath of a silky lustre yellowish brownish-grey with almost the same marking as in the *cecrops*-group (p. 795); the characteristic difference is noticed in the marginal line of the hindwing being black, proximally white and at the ends of the veins regularly sending forth black small triangles inside, so that the white bordering grows undulate and the red spots assume an oval shape being rounded towards the margin. In the present species the postdiscal begins at the costal margin with an isolated, distally displaced spot; the red spots of the tail are double, black, distally pupilled in brown; the submarginal space above them almost unmarked. Guiana to the Amazon.

malta. **Th. malta** Schs. (158 g) is a little larger, above the same, with darker, reddish fringes; beneath browner, not lustrous, the discal streaks more distinct, distally lighter tinged; the postdiscal of the hindwing proximally more broadly bordered by red, at the costal margin rising in a line, the uppermost spot not distally displaced; the submarginal consisting of distinct, darker brown crescents; the red spots of the tail double, but the upper one only half developed, only the one between the median veins black-pupilled. Colombia, Bolivia, Peru.

anthora. **Th. anthora** Hew. (158 g). Above likewise brownish-black with a reddish spot in the anal lobe, beneath darker brownish-grey than the preceding, marked the same as *vesulus*, but the costal-marginal spot of the discal of the hindwing scarcely distally displaced; the submarginal of the hindwing less distinct than in *malta* the red spots of the tail double, both black-pupilled. Guiana to the Amazon.

pennatus. **Th. pennatus** Drc. is allied to the preceding. On the upper surface the proximal margin of the forewing is quite narrow, also the disc of the hindwing dull-lustrous indigo-blue. Beneath the ground-colour is duller, the postdiscal bands narrower, placed more inward, and on the hindwings proximally not bordered by red; there is only one red spot of the tail between the median veins and the triangular, otherwise red filling of the middle angle of the W is replaced here by black colour. The ♀ is above quite dull brown. Amazon.

cerata. **Th. cerata** Hew. (158 g) is easily distinguishable from the others by the dull-lustrous indigo-blue colour of the upper surface, almost without any black margin at all. Beneath the most similar to *vesulus*, still lighter and also lustrous; the submarginal space is not blank as it is there, but feebly marked, close in front of the margin the submarginal crescents are yet filled up by darker small spots. From Guatemala to the Amazon; in the north rarer than in the south. — **palumbes** Drc. is apparently based only on aberrative specimens which are beneath without any postdiscal bands at all. From Cayenne.

pisis. **Th. pisis** Godm. & Salv. (158 d) differs from *cerata* by much darker, purple-black colour above, and more ochreous-yellow colour beneath. Guatemala, Nicaragua, Panama.

pisidula. **Th. pisidula** Drc. (158 h) is above dark indigo-blue with indistinctly defined, narrow, black margins. Beneath darker than *pisis* and of a more olive tinge; on the hindwings there is only between the median veins a dull red spot which is very much smaller; the submarginal line is very distinctly marked on both wings. Brazil (Rio Grande, Sa. Catharina).

tanais. **Th. tanais** Godm. & Salv. (158 h) exactly resembles *pisidula*, but beneath there is instead of the red spot of the tail a second, bluish-grey, oval spot, ringed somewhat lighter blue, and the fine, black, marginal small triangles are more prominent. Panama, Colombia (Rio Dagua).

instita. **Th. instita** Drc. is above plainly dark-brown, beneath marked exactly like *pisidula*, only somewhat darker. Brazil.

puppius. **Th. puppius** Godm. & Salv. is above likewise deep blackish-brown, the wings shorter, the apex more pointed. Beneath marked like *pisis* and *cerata*, but the ground-colour is dirty brown, without a yellow tinge. British Guiana.

meleager. **Th. meleager** Drc. is perhaps only a southern local form of *pisis*; above just as purple-black, but beneath dark greenish-grey, the red spots darker and smaller, their black pupils larger and deeper black. Surinam.

cissusa. **Th. cissusa** Hew. (158 h) is smaller, above blackish-brown, at the costal and proximal margin of the hindwing blue with a blue-white marginal line and small blackish spots before it. Beneath like *vesulus*. Guiana, Amazon, Bolivia.

Th. trebula Hew. (158 h). Forewings above brown-black, hindwings of a brilliant blue with moderately broad black costal and distal margins. Beneath marked as *vesulus* (158 g) on a purely olive-yellow, lustrous ground. From Mexico to Colombia and the Amazon.

Th. orcilla Hew. (158 h). The ♂ is above brown, the ♀ at the proximal margin of the forewing, and on the hindwing of a brilliant azure colour, in the anal direction with a bluish-white subterminal line and small black spots before it. (HEWITSON mixed up the sexes!) On the underside the colour is lustrous light reddish-brown, marked as *vesulus*, but the postdiscal bands are proximally broader orange-red. Ecuador, Colombia, Bolivia.

Th. gizela Hew. (158 i) is above indigo-black, like *pisidula* (158 h), beneath reddish grey-brown with a brown cell-end streak and markings, as in *orcilla*, likewise with postdiscal bands broadly bordered with red. Bolivia.

Th. panamensis sp. nov. (158 i) is the most similar to *pisidula* (158 h), but it is above of a light greenish steel-blue, with a strong lustre, black margins of the same extent as in *pisidula*; the ♀ is of a duller grey-blue. Beneath more purely grey, with a slight lustre, the linear marking stronger, particularly the white bordering more pronounced, the submarginal lunae more distinct, the red spot of the tail very large, so is the light-blue spot beside it. Panama.

Th. pupilla sp. nov. (158 i) is above black-brown, towards the base with a slight blue-grey tint, on the hindwing with a large red anal spot being bordered at first by black, then by white; beneath brown-grey, the lines like in the preceding, but finer; the submarginal lunae almost extinct, from the upper median vein to the proximal margin distinct as an entirely straight black line being removed far inward and touching the dents of the postdiscal band. The red spot of the tail and the anal spot extremely large, connected by a broad red bridge, the black pupil of the spot of the tail very small, strigiform. Guiana to Colombia and Bolivia.

Th. gentilla Schs. is above dull grey-blue, not metallic, with a fine black distal margin. Beneath light grey-brown, marked like *pisidula*, but with whitish cell-end streaks; the W is filled up with black towards the border, both the anal spots connected by a red bridge, the spot of the tail very large black, containing only a small red crescent, the anal spot quite black. Expanse of wings: 20 mm. Petropolis in South Brazil.

Th. aprica Mschlr. may probably belong hereto. The black-brown forewings are of a violet-blue gloss along the proximal margin, the hindwings in the disc; at the anal angle there is a red spot. Beneath dark yellowish-grey, the markings as usually; the postdiscal band of the hindwing proximally black, distally white, without any orange-red; the submarginal band is a whitish dentate line being dark towards the border; between the median veins a large red spot with a black pupil; the grey spot before the anal angle is bordered towards the base by an arcuate red spot, the lower filling of the middle sides of the W being black. Paramaribo.

105. Teucris-Group.

Th. teucris Hew. (158 i). Above dark-brown, at the anal angle of the hindwing a white subterminal line and two minute white spots. Beneath grey, towards the border somewhat browner; the postdiscal band composed of white small spots being proximally bordered with brown, like the submarginal bands. At the costal and anal angles of the hindwing broad carmine spots. Amazon.

Th. milto Godm. & Salv. (158 i) is similar, but above tinted blue, the hindwings dusted with blue. Beneath the postdiscal band is placed much nearer to the border, while on the forewing it is more indistinct. Panama.

Th. tegula Hew. (158 i) is more grey-brown than *teucris* and exhibits a quite uncommonly large, dark brown scent-spot in the cell. Beneath very much like *teucris*, recognizable by a small white spot in the middle of the costal margin of the hindwing. Amazon.

Th. casmilla Hew. (158 i, k) has the same enormous scent-spot as the preceding, being continued for some distance behind the cell, on the forewing with an indigo-blue tint, and the hindwing in the proximal-marginal half strewn with a dull blue, so that the veins, a cell-end streak and small submarginal spots remain black. Beneath light olive-brown, with very much duller markings, the white having almost disappeared; between the two submarginal bands there is some light blue dusting. Brazil (Rio Grande, Sa. Catharina).

106. Ledaea-Group.

Th. ledaea Hew. (158 l) is above dark-brown, in the proximal half of the forewing and on the hindwing except the costal margin and apex grey-blue; the anal spot being bordered with white and two small spots of the tail black-brown. Beneath yellowish-brown with similarly shaped postdiscal bands as in the *vesulus*-group, at the anal angle extensively orange-yellow, the anal spot and the spot on the tail black, the space between brown, dusted with white. Amazon.

caesaries. **Th. caesaries** *Drc.* (158 l) is smaller, above indigo-blue with a broad black apex; beneath more steel-grey, the yellow anal area more extensive, the postdiscal bands removed more inward, proximally and in the angle of the W also distally bordered with orange-reddish; a double cell-streak. This species is undoubtedly only a modification of the *vesulus*-group. British Guiana, Colombia.

107. Mantica-Group.

mantica. **Th. mantica** *Drc.* (158 l) is an isolated species. Above dark brown, at the proximal margin, and in the disc of the hindwing dull grey-blue with a large oval, dull black scent-spot in the cell, bordered with a silky grey; anal lobe spotted orange-red. The ♀ is above much less blue. Beneath light brown, the postdiscal band composed of small separate black spots being distally white, the second of the topmost spots of the hindwing removed far inward; a submarginal broad red band. Brazil (Chapada Campo).

108. Celmus-Group.

celmus. **Th. celmus** *Cr.* (= *echion* var. *Godt.*, *pereza* *Btlr.*) (158 l) is a small delicate species, above with a violet lustrous light blue, with a broad brownish-grey costal margin, apex and distal margin, on the hindwings only very narrowly bordered with white fringes and a white marginal line at the anal angle. Beneath white, the postdiscal band orange brownish, distally bordered with brown, on the forewing coherent, on the hindwing broken up into 5 spots; at the base of the costal margin another 6th spot. The submarginal band is composed of brown crescentiform streaks, being on the forewing more coherent than on the hindwing, here at the anal angle with a small yellow spot, between the median veins a somewhat larger black-pupilled spot. The ♀ is above of a plain brown colour. Distributed from Mexico as far as South Brazil.

lollia. **Th. lollia** *Godm. & Salv.* (158 l) is above deep violettish blue, with a somewhat more narrowly black apex and costal margin, beneath more grey-white, whereby the submarginal band is proximally bordered with a brighter white, the markings otherwise very similar except the absence of the basal spot on the hindwing. Mexico to Costa Rica.

seudiga. **Th. seudiga** *Hew.* (158 l) differs by a still narrower black apex and distal margin, of the costal margin only the base is black, the other part of it like the wing deep ultramarine. The under surface is of a still darker ashy grey, at the cell-end a black fine streak-spot, otherwise marked as *lollia*, the discal bands and spots, however, of a deeper copper-red. Brazil, Bolivia.

jambe. **Th. jambe** *Godm. & Salv.* (158 l) has above a much broader black-brown apex and costal margin than the preceding, something like in *celmus*, so that the cell grows dark, too. Beneath marked and coloured like *seudiga*; the dark submarginal area grows broader, so that two undulate white lunular lines become more prominent on each side of it.

lucagus. **Th. lucagus** *Godm. & Salv.* (158 l) is likewise similar, above more extensively blue as far as the costal margin. Beneath the ground-colour is somewhat more brownish, the dark submarginal band is situate nearer to the border, the red anal spots greatly reduced. Mexico.

asa. **Th. asa** *Hew.* (158 k) is above of the same blue as *celmus* (158 k), but in the whole distal half of the forewing black-brown, in the centre of a darker lustre and with a dark brown scent-spot in the middle of the cell; beneath like *jambe*, the proximal white submarginal series of lunae on the hindwing above the upper and beneath the lower radial vein protruding far inward. Amazon, Colombia.

carnica. **Th. carnica** *Hew.* (158 k) is beneath coloured and marked like *asa*, the proximal submarginal band, however, runs much more regularly. Above deep violet-blue with very narrow black margins. The diminutive animal is smaller on the whole, only northern specimens are somewhat larger and have broader wings. Mexico to the Amazon.

emendatus. **Th. emendatus** *Drc.* (158 k) is allied to the preceding, above lighter and more brilliant blue, the apex of the forewing broader and more uniformly black, the costal margin and apex of the hindwing, however, narrower than in *carnica*. Beneath like *carnica*, but the white submarginal lunae are more prominent. Bolivia.

calchinia. **Th. calchinia** *Hew.* (158 k). Above blue with a broad black-brown apex and costal margin of the forewing. Beneath whitish, similarly marked as the preceding, with fine cell-end streaks and on the hindwing a somewhat more coherent postdiscal band; the submarginal bands are composed of dull grey-brown lunular lines; at the anal angle 2 minute orange-yellow spots. Amazon.

hyccara. **Th. hyccara** *Hew.* (158 k) is above very similar, at the anal angle of the hindwing the minute black spots of *calchinia* are absent. Beneath light grey-brownish; on the forewings the postdiscal band which runs straight and equally broad to the proximal margin, is distally bordered with white, while in *calchinia* it is bent somewhat outward and behind the cell broader than at the costal margin. The ♀ is above brown. Amazon.

uzza. **Th. uzza** *Hew.* (158 k) is above lighter blue, beneath distinguishable by 2 or 3 small basal brown punctiform spots on the hindwings, and extensive red-brownish, small submarginal spots being distally bordered with white. Brazil.

Th. dicaea *Hew.* (= *farmina* *Schs.*) (159 b) is above more extensively blue than the preceding, the *dicaea*. costal margin remains blue. Beneath darker grey without the cell-end streaks; the postdiscal bands dark red, distally bordered with black, then with black, on the hindwings broken up into spots, between the radial veins removed outward. Brazil (Paraná).

Th. dicina *sp. nov.* (159 b) differs above by the deep violet colour and a square black scent-spot in *dicina*. the cell-end, the apex and distal margin narrowly black-brown. Beneath like *dicaea*, but with a much darker, almost blackish-grey ground-colour; both wings exhibit white cell-streaks being on both sides bordered with black. Colombia.

109. Celida-Group.

Th. celida *Luc.* (159 b) is above opalescent sky-blue, the broad apex and a fine marginal line on the *celida*. hindwing black-brown, a rather large scent-spot behind the cell black. Beneath brownish-grey with fine irregularly undulate transverse lines behind the middle, on the hindwings also before the middle, and with fine discal streaks; before the border a fine lunular line, between the tails an orange spot, the anal-angular spot black, strewn with blue. Cuba.

Th. tera *Hew.* (159 b) is closely allied, with broader wings, above more violet; the under surface is *tera*. white, the lines similar, but the basal one is absent on the hindwing, the postdiscal band is proximally bordered with reddish-yellow, the discal streaks are double, at the anal angle there is another small orange spot. Panama, Colombia, Peru.

Th. celona *Hew.* (159 b) is much smaller, of a more radiant blue and more narrowly bordered with *celona*. black, so that the black scent-spot stands out isolated in the blue area. Beneath very much like *tera*, the postdiscal band more coherent. Brazil.

Th. chilica *Schs.*, being unknown to me, is described as follows: forewing blackish, cell and inner- *chilica*. marginal area metallic blue with a large black round scent-spot behind the cell; hindwing metallic blue, costal margin and proximal margin grey, analwards a white marginal line. Beneath whitish with dark cell-streaks, the postdiscal band undulate, red-brown, on the hindwing broken up into spots, distally bordered with black, and with a distinct W towards the proximal margin; small subterminal brown lunae are interrupted between the tails by an ochreous-yellow spot pupilled in black. Expanse of wings: 19 mm. Castro (Paraná).

110. Alda-Group.

Th. alda *Hew.* (159 b). Upper surface violettish-blue, with a small round dark brown scent-spot *alda*. behind the cell and a broad black-brown costal and distal margin. Beneath light reddish-brown with fine cell-end streaks; the postdiscal band similar as in the *celmus*-group, but coherent also on the hindwings, here also with some small basal spots, the one at the costal margin being the largest; the ♀ is above brown. Amazon.

Th. hesychia *Godm. & Salv.* (159 c) is allied, above of a puer violet, beneath without the basal spots *hesychia*. of the hindwing. Costa Rica.

Th. hicetas *Godm. & Salv.* (159 c) is above much darker purple violet, the scent-spot deep velvety *hicetas*. black. Beneath dark brown-grey, on the forewing in the middle of the cell with a dark brown transverse streak, at the cell-end a double streak filled up with whitish; the hindwing exhibits 3 dark basal spots; distal margin with whitish and dark clouds. Mexico.

Th. pactus *Godm. & Salv.* (159 c) greatly resembles *hicetas*, the wings are more purple, beneath the *pactus*. discal lines much broader, scarcely bordered with brown; towards the border there are more intense whitish and dark clouds.

111. Phrutus-Group.

Th. phrutus *Hbn.* (= *fidentia* *Hew.*) (159 c). Forewing brown with a large darker scent-spot; in the *phrutus*. ♂ in the larger, proximal half of the hindwing blue, metallic, in the ♀ the whole hindwing and an inner-marginal stripe of the forewing is duller and more whitish lilac-blue with 2 small black spots at the anal angle; beneath variable, brown, in the distal third whitish, particularly on the hindwing strewn over with carmine, with 2 dentate red lines and a similar cell-streak. Guiana, Amazon, South Peru.

Th. inoa *G. & S.* (159 c) is similar, but above almost white, and beneath the red clouding of *inoa*. the border is absent. Mexico.

Th. zilda *Hew.* (159 c) is above like *phrutus*, the blue lighter and more reduced. Beneath the hind- *zilda*. wings are more extensively whitish and the 2 red dentate lines combined into a middle line; the red strewing of the marginal area is absent. Panama. Costa Rica, Colombia, Brazil.

Th. cruenta *Gosse* is larger than *phrutus*, above very similar, the hindwings more violet in the *cruenta*. disc; fringes brown; the underside is much lighter brown, the red strewing of the margin not so intense, the marking otherwise almost the same. Brazil.

- vena.* **Th. vena** *Drc.* (159 d) differs from the preceding by orange-red fringes, beneath by a straighter post-discal band of the forewing. North West Peru.
- sanguinalis.* **Th. sanguinalis** *Burm.* is above quite grey-brown, similar to the following, without any tails with a slightly extended anal angle of the hindwing and whitish-dotted fringes; the under surface is whitish, with brown clouds and with small spots and bands of carmine. Argentina, Paraguay.
- gamma.* **Th. gamma** *Druce* (159 d) is similarly dull grey-brown, at the proximal margin of the forewing and in the larger proximal half of the hindwing dull grey-blue with orange-red fringes. Beneath brown, in the marginal area of the forewing whitish, strewn with carmine, with a white discal streak; the hindwings exhibit a white median band and at the costal base a small spot bordered with red, in the shape of a γ ; marginal half likewise strewn with red. Argentina.
- megacles.* **Th. megacles** *Cr.* (= *adria* *Hew.*) (159 d). Above black-brown with a small darker scent-spot; the proximal margin of the hindwing is white, so is a marginal line before the anal region. In the ♀ the proximal margin of the forewing and the whole hindwing are of a pure white, the marking beneath showing slightly through. Beneath white, the forewing in the middle clouded brown-grey, with carmine markings like in *zilda* (159 c), but besides with 4 red, small basal spots on the hindwing. Venezuela, Surinam, Amazon.
- coronta.* **Th. coronta** *Hew.* (159 d) is a very much larger species. Above black-brown with a large black scent-spot in the cell, white at the proximal margin of the forewing and in the disc of the hindwing there is a dull blue. Beneath brownish-grey, at the basal half darker, at the costal angle of the hindwing whitish. Both wings exhibit red discal streaks, behind them a band of interrupted, small red spots, distally bordered with white, on the hindwing besides with 5 or 6 small red basal spots; small brown submarginal spots are on both sides bordered with white; anal spots orange. Mexico to Guiana.
- maevia.* **Th. maevia** *Godm. & Salv.* (159 c) is very similar, much smaller, of a duller bluish-grey, the abdomen above reddish-yellow. Beneath dark grey, uniformly strewn with a light grey, otherwise almost the same markings. Mexico to Costa Rica.

112. Una-Group.

- una.* **Th. una** *Hew.* (= *lenis* *Capr.*) (159 d). Above grey-brown, in the ♂ with a narrow bluish inner-marginal stripe of the forewing and a white inner-marginal half of the hindwing, with a white marginal line and a black spot at the anal angle, the forewings exhibit an indistinctly darker cell-spot, the ♀ is on the forewing more extensively bluish as far as up to the cell or even into it; hindwing all white with a brownish-grey costal margin and small black spots in front of the anal margin. Beneath white, the scheme of markings similar to *hicetas* (159 c), but the small spots are composed of brown double streaks which are mostly filled up with some brownish. Brazil, Colombia, Venezuela.
- furcifer.* **Th. furcifer** *Drc.* is closely allied and above just the same, on the hindwings only coloured somewhat more greyish-blue. Beneath light grey, with bands and spots bordered with white and arranged like in *una*, which, however, are but slightly darker than the ground. The small, red-yellow anal spots are absent altogether. Espiritu Santo.
- scopas.* **Th. scopas** *Godm. & Salv.* (159 d). Above coloured like *una*, beneath chalky-white with irregular, light orange macular bands, being doubly bordered with black like in *una*. The distal margin and submarginal lunae darker brownish-grey, the two anal spots rather large, red-yellow, with black pupils. Mexico, Nicaragua.

113. Cleon-Group.

- cleon.* **Th. cleon** *F.* (= *ecbatana* *Hew.*) (159 d). Forewing above dark brown, in the basal half of the proximal margin light violet-blue like the hindwing, with white hair on the proximal margin. Beneath light brown, in the basal area mostly intensely darkened and clouded in grey; both wings exhibit dark cell-end streaks distally bordered by a light tinge. Postdiscal bands broad, dark red-brown, on both sides bordered with blackish, behind it bordered with whitish, projecting below the costal margin on the hindwing, receding in the angle of the lower radial vein and distally mostly with intensely brown-grey clouds. The orange-red anal spots distinct, between them a spot strewn with white. The underside is rather variable in the colour and width of the postdiscal bands. Trinidad, Amazon, Brazil.
- picientia.* **Th. picientia** *Hew.* (= *rubifer* *Drc.*) (159 e) is above unicolorously brown with a reddish spot in the anal lobe. Beneath very much like *cleon*, the ♂ likewise darkened in the basal part, particularly on the hindwing. The postdiscal band of the hindwing is particularly in the ♀ very broad, in the ♂ narrower and distally clouded much more intensely, almost in a blackish brown; the submarginal markings are the same. In the ♂ the hindhead and forehead, as well as the extreme costal base of the forewing are red. The type came from Tapajos, the ♂ having been denoted as *rubifer* in case of specific difference originates from Bogotá, before me there is a couple from the Museu Paulista.
- socia.* **Th. socia** *Hew.* (159 c) is larger than *cleon*, above coloured the same, but besides with a small grey scent-spot at the cell-end. Beneath similarly marked as in the preceding, the postdiscal band of the hindwing projecting almost quadrangulantly between the upper radial veins; the marginal area is profusely strewn with whitish, at the costal angle there is a small red spot. Brazil.
- madie.* **Th. madie** *Weeks* is said to resemble *cleon* (159 d); above the same, only more mouse-coloured, instead of dark brown. Beneath light mouse-coloured, likewise with a lighter marginal area and similar post-

disal bands, running retilinearly on the hindwing from the costal margin to the lower median vein. Expanse of wings: 27 mm. Described from Venezuela (Suapure).

Th. mathewi Hew. (159 e) does not differ above from *cleon*, while the ground-colour beneath is lighter, *mathewi*. less clouded towards the margin, the postdisal bands being much finer and more regular. Mexico to Panama.

Th. verbenaca Drc. (159 e) is above darker and more extensively blue, inclusive of the cell of *verbenaca*. the forewing, with a black spot behind it; anal lobe orange. Beneath dull lustrous greenish-grey, the postdisal band on the forewing only little visible and on the hindwing very fine and narrow, only analwards proximally with some reddish scales, beginning at the costal margin with a distally removed spot; the red anal spots very large. Brazil.

Th. sesara Godm. & Salv. is allied to *mathewi* (159 e) and has the same markings beneath, but above it *sesara*. is entirely brownish-black, not blue, the hindwing with 3 dark submarginal spots at the anal angle. Colombia.

Th. normahal Schs. (159 e) likewise differs little from *mathewi*; above the forewings are quite *normahal*. brown, only at the proximal margin with some lilac-white hairs, the hindwings being haired lilac-white only in the proximal halves; in front of the black marginal line there is a lilac-white line. On the under surface the postdisal band on the forewing extends only to the lower median vein and is not distally bordered by white. Expanse of wings: 21 mm. Peru.

Th. chonida Hew. (159 e) differs above by its dull grey-brown colour being more blue-grey in the inner *chonida*. space, and a very large black discal spot, the hindwing being white in the anal half, with small, black ante-marginal spots, the spot between the tails and the anal lobe being bordered with orange. Beneath lighter than *mathewi*, the postdisal band on the hindwing straighter and not so much curved to the proximal margin. Mexico.

Th. leda Edw. is above black-brown, the forewing in the basal half of the proximal margin and the *leda*. hindwing at the apex blue-grey; at the anal angle two black-brown spots, and in the middle of the forewing a black discal spot; beneath grey, similarly marked as *mathewi*, the postdisal bands proximally bordered with red-yellow, distally with white, on the hindwings more strongly undulate; the submarginal band dark, on both sides bordered with white, with two red-yellow, black-pupilled anal spots. Arizona, Mexico.

Th. clytie Edw. (159 e) is above whitish lilac-blue with a broad black apex and small black anal spots *clytie*. of the hindwing; beneath white, marked very much like *leda*, but the lines much finer and feebler, without any orange. Texas, Arizona.

Th. ines Edw. (159 e) greatly resembles *clytie*, but it is smaller, the forewing somewhat more *ines*. extensively blue, the hindwing with a blackish costal region, beneath slate-coloured with more numerous transverse lines and small orange anal spots, and a darker median shade of the hindwing. Arizona.

Th. avalona Wright (159 f) seems to be allied to *ines*; above brown-grey, towards the base a little *avalona*. more bluish, small dark marginal spots on the hindwing are proximally bordered with a lighter tinge. Beneath more of the colour of a grey horse with a very indistinct marking. California.

Th. cinniana Hew. (159 f). Forewing black-brown, hindwing dull blue, in the ♂ with a dark costal *cinniana*. area; at the anal angle two small black spots. Beneath light brownish-grey, the postdisal bands proximally broadly bordered with red, the spots of the tails double like in the *vesulus*-group (p. 800), connected with the red anal spot by a red bridge proximally to the white-dusted spot. Amazon.

Th. plumans Drc. may be only a local race of the preceding, the blue having almost disappeared *plumans*. above and being noticeable only at the anal margin of the hindwing. Brazil (Chapada Campo).

114. Azia-Group.

Th. azia Hew. (= *nipona* Hew.) (159 f) and its allies are characterized by having only 1 little tail *azia*. at the lower median vein and by a dark scent-spot in the cell of the forewing. Above brown, at the proximal margin of the hindwing in the ♀ narrowly bluish-white with dark, small marginal spots in the anal part. Beneath light grey, marked very much like *dicaea* (159 b) the fine orange-red postdisal band of the hindwing projecting distally at the costal margin and between the radial veins. The 2 red anal spots are large. Mexico to Brazil and Paraguay.

Th. centuncula sp. nov. (159 f) is somewhat smaller, above the same; beneath the ground-colour *centuncula*. is of a carmine or lilac tinge, the postdisal band is much finer, carmine, on the hindwing broken up into spots and much more strongly interrupted, projecting the farthest towards the base between the median veins and below the subcostal vein, the farthest towards the margin between the lower radials; the sharply defined, brown-grey submarginal lunae almost form right angles and are on both sides bordered by lilac-white; the marginal line is scarlet on both wings, the fringes white, on the forewings somewhat brownish. The small anal spots are reduced, the spot of the tail is only a minute red dot. Forehead, hindhead, and costal base of the forewing brownish-red. 1 ♀ from São Paulo.

Th. volumen Drc. is above uniformly dull brown with a small red spot in the anal lobe, beneath *volumen*. coloured and marked as *picientia* (159 e), but it has only one small tail. Brazil (Rio; Chapada Campo). Expanse of wings: 18 mm.

- vidulus*. **Th. vidulus** Drc. The forewings are above dull black, the hindwings light blue, warming towards the base into black like at the costal margin and apex. Beneath like *cinniana* (159 f), but the ground-colour is darker and the red band of the hindwing much broader, in front of it two parallel red discal streaks. Expanse of wings: 34 mm, thus very large. Ecuador.
- rufofusca*. **Th. rufofusca** Hew. (= *lucaris* Weeks) (159 f) is above brown, in the ♂ with an indistinct, large, dark discal spot; before the anal margin of the hindwing a black line being proximally white, before it 3 or 4 small black spots, 2 or 3 of which are inwardly spotted orange. Beneath light grey, marked very much like *azia*, but the postdiscal band has regular orange demi-arcs; the anal spots are minute, orange. Mexico to Brazil, also in the West Indies.

115. Badaca-Group.

- badaca*. **Th. badaca** Hew. (= *collucia* Hew.) (159 f) is above black-brown, in the ♀ towards the base tinted grey-blue. Beneath reddish brown-grey, the postdiscal bands brown, particularly on the hindwings bordered proximally with red, distally with white; the dark, undulate submarginal band is on both sides bordered with a light colour, between it and the postdiscal band on the hindwing dark clouds; the two red anal spots are large. Panama, Brazil, Colombia.
- ceromia*. **Th. ceromia** Hew. (= *suada* Hew.) (159 g) is above the same, beneath more red-brown, the postdiscal bands are proximally not bordered with red or orange, the dark clouds beyond them are absent on the hindwing. Amazon, Bolivia.
- opacitas*. **Th. opacitas** Drc. is closely allied to *ceromia*, above in the disc with a slight copper lustre; beneath the same, but the black anal spots are more prominent, and the postdiscal band is proximally somewhat orange. Forehead, collar, and costal base of the forewing copper-red. Mexico.
- canus*. **Th. canus** Drc. (159 g) has above in the disc a still more pronounced copper lustre; beneath lighter, with a more olive tinge, the postdiscal band of the hindwing broader light orange, the red spot of the tail smaller and crescentiform; easily distinguishable from the preceding species with black palpi by the palpi being almost entirely white. Mexico to the Amazon.
- nubes*. **Th. nubes** Drc. is smaller, the shape of the hindwing not so long-stretched, shorter and rounder; the ground-colour is above blacker, in the disc with a coppery lustre, beneath more olive, the postdiscal bands placed nearer to the margin. Trinidad.
- sangala*. **Th. sangala** Hew. (= *autoclea* Hew.) (159 g). Above like *ceromia*, in both sexes brown, beneath brown, the postdiscal bands of a bright orange-red, distally bordered sharply with white, particularly broad in the ♀, at the costal margin of the forewing with a spot being distally removed and bordered also proximally with brown and then somewhat with whitish; the anal spots are large, of a bright red, the submarginal spots rusty-brownish, towards the costal angle sometimes orange, distinctly bordered with grey-white on both sides. Nicaragua, Venezuela to Bolivia.
- politus*. **Th. politus** Drc. (159 g) is above coloured like *sangala*, but the ♀ dull lavender-blue on the hindwings and narrowly also at the proximal margin of the forewing. Beneath like *sangala*, but the red spot of the tail is removed nearer to the distal margin. Widely distributed in Guatemala, Guiana, Colombia, Amazon, Trinidad.
- syllis*. **Th. syllis** G. & S. (159 g) is closely allied to *ceromia*, but the hindwings are above scaled in blue, and beneath the postdiscal band is broadly bordered with red; the red spot of the tail is proximally bordered with an ochreous yellow, extended as far as the anal angle. Mexico, Guatemala, Nicaragua, Colombia, Amazon.
- amphrade*. **Th. amphrade** Schs. (159 g) of which only the ♀ is known hitherto looks above like *politus*, only darker slate-blue, on the forewing as far as up to the cell; beneath the postdiscal band is proximally dark brown, not orange, on the forewing very indistinct, on the hindwing it runs from the costal margin straight to the lower radial; the spot on the tail and the anal spot are very indistinct reddish. Costa Rica.

116. Melinus-Group. (*Uranotes* Scudd.)

- melinus*. **Th. melinus** Hbn. (= *hyperici* Bsd., *favonius* Bsd., *humuli* Harris, *pan* Harris, *silenus* Dbl., *pudica* Edw.) (159 g). Above brown, the hindwing at the anal angle with a double, blue-white marginal line, between, beginning from the median veins, with small black veins, the uppermost proximally orange-red, like the anal lobe. Beneath light grey, the postdiscal band shaped very much like in *mathevi* (159 e), but finer and at the anal angle with two large orange spots. North America to Venezuela. — **sabinus** Fldr. is probably only the southern form of the preceding, with more extensive and more intensely red anal spots beneath, touching the postdiscal band; the species, however, is on the whole very variable. From Colombia and Brazil.
- valentina*. **Th. valentina** Berg differs from *melinus* by more irregular rusty-brown postdiscal bands being on the hindwing interrupted in some places, beginning much farther distally at the costal margin, and by a red-brown, not black marginal line; on the hindwing there are two very distinct rows of white submarginal lunae. From Argentina.

Th. promissa *Mschlr.* seems to me to belong here. Above brown, at the proximal margin of the forewing and on the hindwing, except the costal part, whitish grey, between the median veins and at the anal angle with orange spots; beneath marked like *valentina*, the ground-colour is described to be yellowish white-grey, the postdiscal band is proximally not bordered with orange. Paramaribo.

117. *Bebrycia*-Group.

Th. bebrycia *Hew.* (159 h) is above blackish-brown, with a large black cell-spot, on the hindwing with a black spot of the tail, being bordered with orange. Beneath grey-brown, on the hindwing with a lilac shine, the postdiscal band black-brown, proximally bordered with red, distally with a pure white; on the hindwing the costal-marginal spot and the spots between the radial veins are projecting farther towards the margin. Mexico, Guatemala.

Th. serapio *Godm. & Salv.* (159 g, h) differs by the violet-blue colour along the proximal margin of the forewing and in the inner-marginal half and along the distal margin of the hindwing; beneath the postdiscal band is in the middle jet-black, proximally red-brown, distally white. Mexico, Panama.

Th. azuba *Hew.* (159 h). Above grey-brown, on the forewing with a large black discal spot, the hindwing in the larger proximal half dull violet-blue with a black spot between the median veins. Beneath like *serapio*, but the postdiscal band on the hindwing is more broken up into spots and of a lighter orange. Brazil (Rio Grande, São Paulo).

Th. tella *Schs.* probably belongs here; above black-brown, the hindwing below the lower median vein dusted with blue. Beneath brown-grey, the postdiscal band reddish brown, distally white, on the forewing as far as the lower median vein, then removed more inward, on the hindwing irregularly broken; before the border there are large submarginal brown spots, being partly surrounded by black; at the anal angle a small black spot. Novo Friburgo.

Th. lemnos *Drc.* is closely allied to *serapio* (159 g, h); on the hindwing the blue is more extensive, so that the whole cell is blue; beneath the postmedian bands are more irregular and finer, more like lines. Inner Colombia.

Th. echinita *Schs.* is above dull blue-grey, the apex of the forewing and the distal margin blackish, on the hindwing towards the anal region a white line, in front of which there are triangular black spots. Beneath grey, the postdiscal band red-brown, distally white, below the lower median vein proximally angled, on the hindwing irregular; small submarginal lunular spots, distally dusted with a reddish brown, the most densely between the median veins and here pupilled black. Mexico.

Th. thenca *Mschlr.* (160 d) may yet be placed here. Above brown with a greyish tinge, the marginal line dark brown, on the hindwing analwards bordered with white. Beneath light grey-brownish; the postdiscal band is dark brown, distally white, on the forewing undulate, removed somewhat more towards the margin from the costal margin to the lower radial, on the hindwing always projecting in one cell, receding somewhat in the next; the submarginal band is grey-brown, curved, towards the base obsoletely whitish; between the median veins and at the anal angle an orange spot with a triangular black pupil. Length of forewings: 13 mm. Surinam.

118. *Oreala*-Group.

Th. oreala *Hew.* (159 h) is a very variable insect, particularly as to its size. The ♂ is above violet-blue, the apex of the forewing and costal margin of the hindwing black-brown with a large black scent-spot in and behind the cell, in the basal part of the cell there are before it brown scales. Beneath brown-grey, towards the apex on the forewing and hindwing more extensively dusted white, with series of orange-brownish spots being at first encircled by black then by white, also in the basal part of the hindwing; submarginal brownish lunar streaks and the usual orange anal spots. The ♀ is of a duller and more reduced blue, with black small marginal spots on the upperside of the hindwing. From Brazil.

Th. lucena *Hew.* (159 h) is somewhat smaller, the blue on the hindwing confined to a narrow inner-marginal stripe; the hindwing exhibits also in the ♂ black marginal spots. Beneath scarcely different. Venezuela.

Th. canitus *Drc.* (159 i) is much smaller, above black-brown, the hindwing in the larger proximal half dull violet with two small black marginal spots; the under surface is marked almost like in *oreala*. Paraguay.

119. *Basalides*-Group.

Th. basalides *Hbn.* (= *ziba* *Hew.*) (159 i) is above black-brown, with a large black discal spot, and uncommonly variable with respect to the extension of the blue colour: mostly two very narrow stripes along the median and submedian on the forewing and in the disc of the hindwing, so that the cell is yet blue, whereas the space between the radial veins is black; all the blue colour, however, may also be absent altogether; before the distal margin of the hindwing there are black spots, the largest of which is between the median veins; if the blue is absent, mostly 1 or 2 of them are above bordered with orange. Beneath very much like *serapio* (159 h),

but besides with 2 or 3 small red basal spots on the hindwing; the postdiscal band is here broken up into small spots. The ♀ is all brown, on the hindwing with bluish-white, small submarginal lunae, being partly double behind the orange spot. Most widely distributed and mostly common, from Mexico to South East Brazil.

arola. **Th. arola** Hew. (159 i) is above blackish-brown, in the basal half of the proximal margin of the forewing and on the hindwing dull lilac-blue with two small black spots before the anal margin. Beneath similar, distinguished by cell-end streaks, the postdiscal band being placed more proximally, the two uppermost small spots of which are placed still farther towards the base in the hindwing, and by 4 larger basal spots. Brazil.

cardus. **Th. cardus** Hew. (159 i, k) is above of a duller colouring and smaller than *arola*, while it differs beneath by its white ground-colour; the macular markings being arranged similarly as in *arola* are light brownish, distally bordered at first by brown then by white; the ♀ is more brownish beneath, and above plainly brown, only faintly tinged blue with 3 small white spots at the distal margin of the hindwing. Brazil.

tigonia. **Th. tigonia** Schs. resembles *basalides* (159 i). Above brown, on the forewings with two narrow, parallel blue stripes at the proximal margin, and in the proximal half of the hindwing dull blue with black marginal spots, the one between the median veins being above bordered with red. Underneath it differs by plain whitish submarginal small lunae without a darker filling. Peru.

120. Albata-Group.

albata. **Th. albata** Fldr. (159 k) is above grey-brown, with a pale blue tinge at the base of the forewing, the hindwing white, somewhat grey towards the base with minute black antemarginal spots. Beneath white, in the basal half pale grey, on the forewing the bordering between the median veins projects towards the margin while on the hindwing it is irregular. Indistinct double antemarginal rows of lunae. Panama, Colombia, Venezuela.

sedecia. **Th. sedecia** Hew. (159 k) is very similar, without any blue at the base of the forewing, with a black distal margin of the hindwing. Beneath the bordering of the grey basal part runs straighter, and at the cell-end there is a white streak; the anal spots are more broadly bordered with red. Mexico, Guatemala.

121. Yojoa-Group.

yojoa. **Th. yojoa** Reak. (= *daraba* Hew., *beroea* Hew.) (159 k). ♂ above brown with a large black scent-spot in the cell and 3 small black spots before the anal margin of the hindwing, fringes whitish. The ♀ has broader wings and a duller colouring, the hindwings are whitish towards the distal margin. Beneath light brownish grey with white cell-streaks and a reddish, distally white postdiscal band being on the hindwing distally removed between the radial veins, proximally below the lower median vein; in the whitish marginal part there are double rows of brownish spots, which are bordered with orange between the median veins and at the anal angle; the hindwing exhibits in the basal part besides a whitish diffuse spot. Widely distributed from Mexico to the Amazon.

alea. **Th. alea** Godm. & Salv. (159 k) is similar, but the hindwings are blue at the distal margin with black submarginal spots. On the under surface the white cell-streaks are absent, the spot of the tail is proximally bordered with reddish-brown. Mexico.

mulucha. **Th. mulucha** Hew. (159 l) is very similar, above like *yojoa*, beneath browner, at the apex of the forewing, in the discal area and at the border of the hindwing white, the postdiscal bands much more strongly broken and composed of small lunar spots, very variable in the intensity of the markings. Guatemala to the Amazon.

thordesa. **Th. thordesa** Hew. (159 l) is considerably larger, beneath almost the same, but above the ♂ is of a lustrous blue with brown margins and an oval red-brown discal spot. The proximal margin of the forewing beneath is faintly tinged blue, the anal spots above bordered with red. Venezuela.

faunalia. **Th. faunalia** Hew. (= *deborrei* Capr.) (159 l). Upper surface brown, in the ♂ with a dark cell-spot, on the hindwing with an analwards white marginal line and 2 or 3 minute black spots before it. Beneath the forewings are light reddish-brown, at the apex whitish with a double row of submarginal spots, in front of which there are 6 dark brown small spots bordered distally by white, proximally somewhat by reddish. Hindwings marked not unlike *mulucha*, but much more irregular and more spotted, with a small black spot on the tail. Amazon, Bolivia. — **dion** Schaller is a species not to be identified, perhaps allied to *faunalia*.

hygela. **Th. hygela** Hew. (159 l) is above deep purple violet with black-brown margins and an almost square black scent-spot at the cell-end; the ♀ is dull brown with a white marginal line in the anal part of the hindwing. Beneath the hindwings resemble those of *faunalia*, though they are still more irregular and more spotted, the forewings are whitish, irregularly clouded brown with large dark brown spots in the middle of the cell and behind it. Brazil, Colombia, Bolivia.

Th. crossaea Hew. (159 l) likewise approximates *faunalia*. Above brown, hindwing towards the *crossaea*. base strewn with blue, before the anal margin with small black spots. Beneath marked similarly to the said species: forewings reddish-brown, at the apex white, clouded brown with 6 dark, distally white spots in front of it. Hindwings whitish, clouded brown, with 4 large dark brown basal spots, cell-streak and interrupted postdiscal macular band like there. Patria not stated.

Th. legota Hew. (159 l) is above brown, at the proximal margin of the forewing and in the larger *legota*. proximal part of the hindwing dull violet-blue. Beneath marked almost like *crossaea*, the forewing with a red-brown cell-end streak and a postdiscal band composed of black double streaks, inside filled up with reddish-brown and outside bordered with white; at the base of the hindwing only 2 spots. Bolivia.

Th. veterator Drc. (159 l) is above dull black-brown, in the basal inner-marginal half of the forewing, *veterator*. and on the hindwing light lilac-blue; scent-spot large, dull, in the distal half of the cell. Beneath marked similarly to *yojoa*, but the ground-colour is much duller brownish without the white admixture, the white cell-streaks and the white shade in the basal area are absent. Paraguay.

122. Bubastus-Group.

Th. bubastus Cr. (= *salona* Hew.) (145 h) is above brown with an indistinct dark brown discal spot *bubastus*. and dark spot at the anal angle of the tailless hindwing. Beneath light reddish-brown, on the hindwing towards the base grey; on both wings with large conical, distally white spots at the border; the postdiscal bands are composed of black-brown small spots being distally bordered with white, and are on the forewing placed very near to the distal margin; in the basal area of the hindwing two spots, the spot of the tail above bordered with red. This tailless form flies in Guiana, Venezuela, Amazon, Brazil, Paraguay, St. Vincent, Dominica, Grenada. — For the tailed form: **eurytulus** Hbn. (= *cybira* Hew., *modesta* Mayn., *ocellifera* Grt., *istapa* Reak., *columella* *eurytulus*. F.) (145 h), occurring in the southern states of North America, in Mexico, Guatemala, Costa Rica, Panama, and in Hayti, Cuba, Jamaica and the Bahamas, a special genus was established: *Callicista* Grote.

Th. sapota Hew. (145 h) entirely resembles above the tailless *bubastus*, beneath it is likewise similar, *sapota*. the ground-colour somewhat darker, the spots being all smaller, more in the shape of streaks, and on the hindwings the basal spots are absent. Peru.

Th. arcula Drc. (145 h) somewhat resembles *sapota* and is tailless, too, but it has quite a different, *arcula*. large, dark scent-spot almost filling up the cell; the hindwing is in the anal half dark violet-blue, which colour extends along the distal margin up to the costal angle. The underside is similar to that of *sapota*, but it is darker purple-brown with white cell-end streaks and a straighter, more coherent postdiscal line and two larger orange anal spots. Paraguay and Argentina.

Th. argona Hew. (= *rana* Schs.) (145 h). Above like *eurytulus* with a smaller scent-spot in the cell; *argona*. at the anal angle of the hindwing there are three larger black-brown spots which are surrounded with grey-blue in the ♂ only traceably in the ♀ much more extensively. Beneath somewhat lighter and browner, the spots rounder, distally bordered with white, on the hindwings proximally with orange; the broad, white submarginal dusting is absent, the anal spots are more orange-red. Brazil, Argentina, Paraguay.

Th. ligia Hew. (145 h) resembles the preceding above in the ♂, but it has some light violettish blue *ligia*. at the proximal margin of the hindwing; the ♀ has more extensively light blue hindwings, and also in the basal half of the proximal margin on the forewing blue dusting. Beneath brownish-grey with cell-end streaks, beneath similar to *eurytulus*, the wings in the distal parts very much clouded brown and dusted white with an orange spot on the tail and a black anal spot. Colombia.

Th. limenia Hew. (145 i). Above similar to the preceding, beneath easily discernible by the postdiscal *limenia*. band of the hindwing losing itself into a line in the anal half and forming a V; the red anal spots, particularly the spot on the tail very large, orange-red and connected by a red bridge above the blue-dusted interspace. Cuba, Jamaica, San Domingo.

Th. angelia Hew. (145 i) is very closely allied to *limenia* and differs above by the red-brown disc in *angelia*. the ♂, beneath by the absence of the basal spots on the hindwing. Cuba, Jamaica.

Th. dominicana Lathy is probably only a modified insular form of the preceding; above the coppery *dominicana*. spot is confined to the basal half of the proximal margin of the forewing, and to traces on the disc of the hindwing; beneath there is a complete postdiscal transverse line which is bordered on the hindwing proximally with red from the upper median vein to the costal margin. Expanse of wings: 23—31 mm. Dominica.

123. *Thius*-Group.

- cestri*. **Th. cestri** *Reak.* (145 i) is characterized by the forewing being somewhat angular on the lower radial vein, the hindwing tailless, with a somewhat protracted anal angle. Above brown with a large black discal spot at the cell-end of the forewing; the hindwing towards the base with blue-grey hair, and between the median veins a small black marginal spot. Fringes white, on the forewing speckled darker. On the under surface the forewing is brown with a whitish apex, the hindwing in the discal area and at the margin whitish with irregular macular stripes and a black small spot between the median veins before the border. In the ♀ the hindwings are above extensively blue. Mexico to Costa Rica.
- cydia*. **Th. cydia** *Hew.* (145 i) is smaller, the ♂ above also blue like the ♀, the latter exhibiting above in the costal part of the hindwing at the apex a large square brown-grey spot. Beneath there is little difference. Brazil, Colombia, Paraguay.
- davara*. **Th. davara** *Hew.* (145 i) does not differ above from *cydia*, it therefore has blue on the hindwings also in the ♂, beneath the hindwings are more whitish, the spots at the base of the hindwing are partly confluent with those of the postdiscal band, on the rusty-yellow forewing the postdiscal band is more coherent. Brazil (São Paulo).
- thius*. **Th. thius** *Hbn.* (= *agra* *Hew.*, *bazochii* *Godt.*, *infrequens* *Weeks*) (145 i, k). Forewings like in the preceding, but less angled, the hindwing except the costal-marginal part quite light lilac-blue, the black marginal spots extremely small. Beneath also marked like the preceding species, the marking, however, is partly covered by brown colour, consisting of a large triangular spot at the costal angle of the hindwing, a similar one in the basal part of the proximal margin, and a small one at the base of the costal margin above it; from the base a light stripe runs along the lower radial vein through the cell to the margin. Brazil, Colombia.

124. *Americensis*-Group.

- americensis*. **Th. americensis** *Blch.* (145 i) is above plainly brown, with whitish grey fringes, without a tail. Beneath light brown, on the forewing with 5 small black postdiscal spots, the hindwing with 2 basal spots and a postdiscal, irregularly curved row of spots, which is analwards proximally somewhat orange; small submarginal brownish spots, at the anal angle and between the median veins spotted orange. Chile.
- tucumana*. **Th. tucumana** *Drc.* (145 k) greatly approximates the preceding, above with some lilac-blue on the hindwing and 3 small black anal spots, beneath just like *americensis*, but at the costal margin of the forewing and across the whole hindwing thickly strewn with grey and brown, so that the markings grow indistinct. Argentina.
- bicolor*. **Th. bicolor** *Phil.* (= *quadrimaculata* *Hew.*) (145 k) is easily discernible above from *americensis* by the large orange discal spots on both wings. Beneath the ground-colour is greyer, in the disc of the forewing likewise orange, otherwise marked like *americensis*. Chile.
- heodes*. **Th. heodes** *Drc.* (145 k) differs from the preceding species by the basal area being dusted with a peculiarly lustrous grey-white on the upper surface of both wings and also at the proximal margin of the forewing; the orange spot of the hindwing is reduced in the ♂, while in the ♀ it is absent altogether. Beneath light brown, strewn with white, marked like *bicolor*, but the postdiscal bands placed nearer to the margin. The ♀ is lighter and almost without any marking. The ♂ is without the dark discal spot exhibited by the preceding species above. Described from North Peru.
- tegaia*. **Th. tegaia** *Hew.* (145 k) we append yet here. Above brown with an orange spot at the anal angle of the forewing and at the border of the hindwing, which is narrower in the ♀; the ♂ exhibits an oval, dark brown scent-spot bordered with a still darker colour. Beneath grey-brown, with dark cell-end streaks and with postdiscal bands composed of black, white-ringed spots, running parallel to the margin; beyond them similar submarginal rows of spots, on both wings analwards distally bordered with orange. From British Guiana and Brazil.
- atrana*. **Th. atrana** *Schs.* (145 k) being allied to the following species may be placed here as a transition. Above brown with a broad red-yellow marginal band of the hindwing. Beneath light grey-brown, on the forewing with three small brown, distally white postdiscal spots; hindwing with a postdiscal row of black lunular spots, being proximally bordered with vermilion, distally with white; black submarginal lunae bordered proximally with white border on a broad vermilion marginal band which projects towards the margin on the ends of the veins and extends from the anal angle to the middle radial; behind there are yet brown marginal lunae and a black marginal line. Expanse of wings: 21 mm. Brazil (Paraná).
- tarania*. **Th. tarania** *Hew.* (145 k, l), a well-known common species, differs in the ♂ at once by the black-brown scent-spot in the cell of the forewing; the orange colour on the hindwing is confined to three small coherent spots at the anal angle, in the cell-spaces between proximally dusted whitish, distally spotted black; the red marginal band of the hindwing beneath, however, extends farther than to the middle radial, mostly even beyond the upper radial. Brazil.

Th. titus *F.* (= *mopsus* *Hbn.*) (145 l) for which the subgenus *Strymon* *Hbn.* could be used is *titus*. above plainly grey-brown, in the ♀ occasionally with traces of red anal spots of the hindwing. Beneath likewise dark brown with a broad red marginal band of the hindwing and smaller, separated spots on the forewings. The larva lives on cherries and plums. In North America widely distributed from Maine to Georgia.

125. Dumenilii-Group. (*Polyniphes* *Kaye.*)

Th. dumenilii *Godt.* (= *argiva* *Hew.*) (145 l) is above white, the apex and costal margin broadly sepia- *dumenilii*. coloured, in the ♂ with a black scent-spot in the cell-end. The ♀ is dusted grey-brownish towards the base, on the hindwing with a fine black marginal line and small black spots before it. Beneath white with reddish-brown transverse lines, a small black, white-ringed costal eye-spot on the hindwing and high submarginal lunae which are pupilled in brownish, between the median veins in black. The ♂ is beneath sometimes without any marking. — In f. **obscura** *Stgr.* the ♀♀ are above monotonously dark brown-grey, whereas the darker ♂ is bluish *obscura*. on the light inner-marginal area of the forewing. Beneath grey-brown with very distinct markings, particularly the distal-marginal eye-spots almost black. Venezuela, Colombia.

Th. tadita *Hew.* (145 l) has a more pointed shape of wings and the white parts above are dull sky-blue; *tadita*. beneath brown-grey, otherwise marked like the preceding. Brazil.

Th. datitia *Jones* (145 l) is very near to the preceding, but it has two tails, and a narrow black border *datitia*. of the hindwings above. Beneath the hindwing exhibits a marginal row of black-pupilled, brown lunae. Paraná.

Th. euptychia *spec. nov.* (145 l) has the shape of *tadita*, but it is all brown with a black scent-spot, *euptychia*. on the hindwing analwards a white border-line and between the median veins a small black spot bordered proximally with a light colour. Beneath the disc of the forewing is rusty yellow, distally brown-grey, the hindwing brown-grey, with the same marking as in the preceding, the costal-marginal eye-spot very large, jet-black, white-ringed, also the spot between the median veins and one above it jet-black, upwards with a golden yellow ring. Described according to a ♂ from the Museu Paulista from South Brazil.

5. Genus: **Theclopsis** *G. & S.*

Differs from the preceding genus by the quinquepartite and unmerged tarsus with claws. The two subcostal veins rise widely separated the 2nd somewhat before the cell-end; the cell itself is uncommonly long with a large scent-spot.

Th. eryx *Cr.* (= *lydus* *Hbn.*, *ingae* *Sepp.*, *lebena* *Hew.*) (145 g) is above metallic ultramarine blue *eryx*. with a black-brown apical half, and a large black discal spot. Beneath lustrous grey-green with brown, distally white postdiscal rows of spots, arranged like in the *vesulus*-group, and with indistinct, small, brown submarginal spots; anal spots red, between them whitish dusting; at the proximal margin of the forewing there is a large black velvety spot partly covered by the costal margin of the hindwing. The ♀ is above dark brown with a dull green-blue disc of the hindwing; beneath more grey-brown with more distinct and brighter markings. Southern specimens have above a more extensive blue and beneath broader red spots. Guiana, Brazil, Ecuador, Peru, and Bolivia.

Th. curtira *Schs.* (145 g) differs little from the preceding. On the upper surface the apex and distal *curtira*. margin, particularly of the hindwing, are broader black, the scent-spot somewhat smaller, more red-brown. Beneath the ground-colour is of a purer grey, only with a slight green lustre, the small submarginal spots form more distinct triangles, proximally bordered with white, the anal spots more orange. Described from Venezuela.

Th. demea *Hew.* (145 g) is easily separated by the absence of the scent-spot and by the black distal *demea*. margin being only very narrow; beneath darker, more blackish, with the same markings, but without the black inner-marginal spot of the forewing. Nicaragua, Colombia.

Th. caeus *G. & S.* (145 g) greatly resembles *demea*, but it has a small crescentiform, brown scent- *caeus*. spot, and beneath the inner-marginal area of the forewing exhibits an intense green lustre; the latter may, according to DRUCE, also be absent in specimens from Colombia and Venezuela; described from Panama.

6. Genus: **Lamprospilus** *Hbn.*

Closely allied to the genus *Thecla* and separated only by few exterior marks, the head and thorax being comparatively very stout, the one species exhibiting small hyaline spots, the other species whitish, thinly scaled, band-like spots on both the wings. The generic separation is scarcely justified.

genius. **L. genius** *Hbn.* (145 f, g) is above brown-black, in the disc with a bluish-grey lustre, on the forewing between and above the median veins with 2 small hyaline spots of a blue opalescence on being exposed to the light laterally; the hindwing exhibits a large opalescent hyaline spot in the cell, below and behind it 2 very small ones. The under surface is bone-coloured, the hyaline spots are of a more intensely blue lustre than above; the basal areas on both wings and a triangular costal-marginal spot on the forewing are dark brown; the post-discal band with a sharp W at the proximal margin; the anal spots and those on the tails reddish-yellow, pupilled black. Surinam to Brazil.

nicetus. **L. nicetus** *Fldr.* (145 g) is more slender, the spots of a dull white, only little transparent, more band-like. Beneath dark brown with white transverse lines, the one on the hindwing very broad, similar as in *Th. teatae*, the orange anal markings very extensive. From Colombia.

II. Group: Chrysophanini.

7. Genus: **Chrysophanus** *Dbl.*

The nearctic flame-coloured lepidoptera do not differ essentially from the palearctic forms: we also find here nearly uniformly large, above golden-red or purple-violet species. The undersides likewise exhibit designs of markings and colourings entirely analogous to the well-known species of the eastern fauna. The biological conditions are also conforming to it, the habits of the larva living on *Rumex* etc. A characteristic mark for the separation of the group from the *Theclini* is the 3-branched subcostal, which they share with the *Lycaenini*.

Otherwise the venation exhibits few differences; on the forewing the discocellular is almost quite absent. On the hindwing the anal angle is mostly somewhat pointedly protracted, and the hindwing is often extended at the lower median vein into a small short tail. As to the habits compare what has been said in the Palearctic Part Vol. I., p. 281.

This genus has likewise been divided by SCUDDER into a number of other genera which, however, are only to be regarded as subdivisions, their names being, therefore, only shortly mentioned.

1. Subgenus: **Tharsalea** *Scudd.*

arota. **Ch. arota** *Bsd.* (145 a). The ♂ is above purple with a violet lustre and small diaphanous spots beneath, the ♀ yellow-red, spotted black with darkened basal halves and margins. The underside is light grey, in the ♀ on the disc of the forewing yellow-reddish; the hindwing exhibits beside the spots a fine black, postdiscal, dentate line, behind it a broad, whitish submarginal band. California. — The larva divergently lives on *Ribes*.

virginiensis. **Ch. virginiensis** *Edw.* (145 a) is on an average somewhat larger, above almost the same, beneath darker grey, more coarsely spotted, and with distinct white submarginal lunae. California, Nevada and Colorado.

hermes. **Ch. hermes** *Edw.* Here also the ♂ is above light red-yellow, at the costal margin and border and at the base brown with the same spots as the preceding, the hindwing much darker, with a long pointed tail; the ♀ has somewhat more distinct markings. Beneath the ground-colour of the forewings is more tawny, at the border grey, the hindwings also in the basal area grey, similarly spotted as the preceding. Expanse of wings: 22 to 27 mm. California, Nevada.

del Sud. **Ch. del Sud** *Wright* (145 b) seems to me to be the best founded upon an aberrative specimen which may well be numbered among this subgenus. The animal resembles the ♀ of *arota*, but the forewings are without the spots in the distal half of the submedian area, and the apex is broadly darkened. Beneath the hindwings are monotonously yellow, almost without spots. California.

2. Subgenus: **Gaeides** *Scudd.*

xanthoides. **Ch. xanthoides** *Bsd.* (145 a) is one of the largest species, above likewise purple-brown, in the ♀ more or less light yellow-red, in both sexes with an orange distal margin of the hindwing, in which there are black spots. The under surface is very pale yellowish-grey, distally white, with the usual black spots being white-ringed on the hindwings; those at the border are analwards proximally bordered by orange lunar lines. The species only flies in California.

dione. **Ch. dione** *Scudd.* (145 b) looks very much like *thoë* (145 c). Above more purely grey-brown with a faint violet lustre, the forewing with 2 black spots in the cell, the hindwing with an orange marginal band. Also the underside is very similarly coloured and marked, but the spots of the hindwings are differently arranged and the forewings likewise grey. The size is larger than in *thoë*. Iowa.

Ch. editha *Mead* (145 b) is smaller than *xanthoides* with somewhat less pointed wings, otherwise above *editha*, very much alike. The under surface is grey with an ochreous-yellow tint increasing towards the margin; the spots are black only on the forewings, on the hindwings ochreous-grey, finely ringed black. Nevada.

Ch. gorgon *Bsd.* (145 b, c). Upper surface lighter purple red with an intense blue-violet lustre, in *gorgon*, the ♀ much more extensively yellow-red. The under surface is yellow white, between the two submarginal rows of spots there is a complete row of orange lunae on the hindwings. The species is so far known only from California and Nevada.

3. Subgenus: *Chrysophanus* *Hbn.*

Ch. thoë *Bsd.* (145 c) has purple-brown forewings with a violet reflection and brown hindwings *thoë*, with an orange marginal band; the ♀ entirely resembles our *virgaureae*. Beneath the forewings are red-yellow in the disc, grey at the apex, the hindwings blue-grey with a red marginal band with the usual small black spots. Distributed and common in the Atlantic States and Colorado. The larva lives on *Rumex*.

4. Subgenus: *Epidemia* *Scudd.*

Ch. mariposa *Reak.* (= *nivalis* *Bsd.*) (145 c). The ♂ is above purple-brown with a violet reflection, *mariposa*, the ♀ extensively yellow-red with the usual small spots. Beneath the forewings are dull yellow-red, the hindwings ashy-grey. This little species is known from California and the Rocky Mountains.

Ch. zeroë *Bsd.* (= *ianthe* *Edw.*) (145 d) greatly resembles the preceding, but it is larger, more *zeroë*, slender, and the wings are more pointed, the ♂ exhibits a more distinct red-yellow marginal band on the hindwing, the black spots, particularly in the ♀, are clearer and more distinct. The under surface is of a duller colouring, the hindwing almost unspotted. California, Colorado.

Ch. helloides *Bsd.* (= *castro* *Reak.*) (145 d) likewise resembles the two preceding species, it is above *helloides*, more brightly coloured and more intensely spotted, and in the ♀ in the basal parts of both wings, particularly of the hindwings, darkened by brown. The under surface is like in *mariposa*, the hindwings of a more reddish tinge. California, Rocky Mountains.

Ch. dorcas *Ky.* (145 d) is smaller than the preceding, the ♂ above deeper violettish-purple, the *dorcas*, ♀ almost entirely darkened by brown. The under surface is almost monotonously yellow-red-brown. Distributed in Arctic America. — The form: *florus* *Edw.*, described from the Red Deer River, is larger with a much broader *florus*, black marginal band almost reaching the discal, zig-zag shaped macular series; the under surface is more light brown.

Ch. epixanthe *Bsd.* (145 e) is the smallest species, above darker, with a faint violet lustre and but *epixanthe*, few small orange spots, at the anal angle of the hindwing; the ♀ is above dull grey-brown. Beneath the wings are of a lighter grey, towards the base more blue-grey with the usual spots. From the northern Atlantic States.

5. Subgenus: *Heodes* *Dalm.*

Ch. hypophlaeas *Bsd.* (= *phlaeas* *Bsd.* & *Lec.*, *americana* *d'Urb.*, *fasciata* *Streck.*, *fulliolus* *Hulst*) *hypo-* *phlaeas*, (145 c) is the North American representative of our common *phlaeas* from which it differs above by the more fiery golden red colour, and by the greyer under surface of the hindwings and more prominent black spots. Everywhere common in North America, only in the Gulf States it is absent. The larva lives on *Rumex* as with us.

Ch. arethusa *Dod.* is closely allied to the preceding; forewings in the ♂ more pointed, the yellow-red *arethusa*, colour above more reduced; on the dark brownish hindwings 2 postmedian rows of spots and the black discal spot are more prominent. Beneath the forewings are of a purer yellow, the spots distinctly light-ringed; the grey hindwings exhibit beside the rows of small black dots an orange-red submarginal line. Expanse of wings: ♂ 30 to 35 mm, ♀ 29 to 33 mm. Rocky Mountains (Calgary).

6. Subgenus: *Chalceria* *Scudd.*

Ch. cupreus *Edw.* (145 e) is above red-golden with a narrow black margin, and in the ♂ with spots *cupreus*, beneath shining through, which in the ♀ appear also above distinctly black. The under surface is light grey-yellow, in the disc of the forewing red-yellow, of the same colour is a marginal band of the hindwing. California, Oregon.

Ch. snowi *Edw.* (145 e) is somewhat larger, above with somewhat broader black margins and also *snowi*, in the ♂ with more distinct, small black spots. The hindwings are beneath more dirty grey. Rocky Mountains.

Ch. rubidus *Edw.* (145 f) entirely resembles *cupreus* above, but it is considerably larger, the ♀ is duller *rubidus*, and more yellow. The under surface is light grey, almost white, the hindwings almost without any spots, while in the form *sirius* *Edw.* (144 n) they exhibit the usual spots like in the other species. Occurring in the Rocky *sirius*, Mountains and Oregon.

7. Subgenus: **Iophanus** *nov.**pyrrhias.*

Ch. pyrrhias *G. & S.* (145 f) is an entirely deviating animal which ought to form a special genus but in the structure it entirely corresponds with *virginiensis*. Above purple with black veins, the hindwings with red submarginal lunae and a violet antemarginal line. Beneath rosy-brown, with an ochreous disc of the forewing and three transverse lines and cell-end streaks. Hitherto only found in Guatemala at altitudes of 6 to 7000 feet, flying close to the soil and fond of resting on pig's droppings.

8. Genus: **Feniseca** *Grt.*

The only genus being quite uncommon to the American fauna, by reason of its structure and biological behaviour, shows unmistakable alliances to the Indo-Australian *Gerydinae*. The body is relatively stout, the wings longer and narrower than usually; the antennae are short and stout with a non-deposited club. Palpi comparatively long, with a long pointed terminal joint. On the forewing the lowest subcostal vein is short-petioled with the upper radial, otherwise there are no differences from the preceding genus. The life-history of this peculiar animal is well known.

The egg is hemispherical, more flat than high, covered with numerous fine longitudinal and transverse ribs enclosing polygonal cell-spaces. The larva looks like a short slug and is covered with many bristly hairs to which the crusts and exudations of the aphids forming the food of the larva adhere. The brown pupa on its dorsal side shows an exact imitation of the shape of a monkey's face with the eyes, nose and mouth as elevations and cavities.

tarquinius.

P. tarquinius *F.* (= *crataegi* *Bsd.*, *porsenna* *Scudd.*) (145 f) is above lustreless yellow-brown with a black-brown costal margin and distal margin and some small spots which vary greatly in extent or may be absent altogether. Beneath the colouring is lighter, at the costal margin and on the hindwings more cinnamon-brown, strewn with lilac-white and marked with numerous darker, whitish-ringed spots. Common in the Atlantic States from Nova Scotia to Carolina.

III. Group: **Lycaenini.**9. Genus: **Lycaena** *F.*

Characteristic is the course of the uppermost subcostal vein which is separated from the costal vein; the lowest subcostal vein is one-partite. Palpi scaled, the two first joints covered with short, dense, bristly hairs. Comp. for further particulars Vol. I, p. 298.

1. Subgenus: **Satyrium** *Scudd.**fuliginosa.*

L. fuliginosa *Edw.* (= *suasa* *Bsd.*) (144 a) is above monotonously dark grey-brown in both sexes. Beneath it resembles the European *semiargus* (Vol. I, p. 119, t. 82 e), lighter brown-grey than above, towards the base, preponderantly on the hindwings, with a bluish tint and a curved row of black, white-ringed post-discal eye-spots, similar discal spots and more indistinct submarginal lunae. California, Utah, Nevada.

2. Subgenus: **Cupido** *Schrank.**heteronea.*

L. heteronea *Bsd.* (144 a) is in the ♂ above light blue with lighter veins and a fine black border, the ♀ is brown with diaphanous spots on the under surface. The latter is almost white with large, jet-black postdiscal spots on the forewings; on the hindwings they are quite light brownish; on both wings they recede towards the base between the median veins. Colorado to California.

clara.

L. clara *Edw.* (144 a) greatly approximates the preceding, and is smaller on an average, the ♀ above extensively dusted light blue, with distinctly diaphanous spots on the under surface which is somewhat duller, more brownish, with several spots in the basal area also of the forewing. Sonora, California.

lycea.

L. lycea *Edw.* (= *rapahoe* *Reak.*) (144 a). Likewise very similar to *heteronea*, the ♂ with a more broadly smoky border of the wings; beneath somewhat darker, the forewings without any basal eye-spots, the series of eye-spots on the hindwings clearer, fine black, white-ringed. Distributed in the Rocky Mountains.

fulla.

L. fulla *Edw.* (= *fuliginosa* *Streck. nec Edw.*) (144 a, b) is smaller than the preceding, the ♂ above of a purer blue; the under surface is light grey with rows of very similar, white-ringed eye-spots, like *lycea*, but the postdiscal row is less curved; at the cell-end of the hindwing there is a white spot. Pacific States.

L. icarioides Bsd. (= *pardalis* Behr, *erymus* Bsd., *mintha* Edw.) (144 b) extremely resembles *fulla*, *icarioides*. above blue, towards the border somewhat darker; the under surface is more grey-brown, in the ♀ still darker; in the basal area slightly dusted with blue, with a large, reniform discal spot which is obsolete on the hindwing; the postdiscal row of eye-spots of the forewing is a straight line between the proximal margin and the upper median vein, by which it differs from most of the other species; submarginally only one row of brownish punctiform spots, the fine black marginal line, being present otherwise, is absent here altogether. Rather rare in South California. — f. **maricopa** Reak. is above brown with a violet lustre and obsolete roundish spots at the *maricopa*. border of the hindwing, beneath dark ashy-brown towards the base.

L. daedalus Behr (144 b) is smaller, of a deeper and purer blue with broader black margins, the *daedalus*. is brown with red-yellow marginal bands which may attain a very considerable width. Beneath darker brown-grey with the usual rows of eye-spots which are just as well developed on the hindwings as on the forewings; the submarginal rows are double, on the hindwings in the middle more or less spotted orange. Common in South California.

L. hilda Grinnell is very near to *daedalus*, above lustrous deep blue with a broader black border *hilda*. and a black reniform discal spot; at the anal angle of the hindwing some black spots; fringes snow-white. Under surface on an ashy-grey ground marked thickly and sharply prominent, the postdiscal band forming an angular semi-circle; at the anal angle of the hindwing there are only 3 small orange spots. The ♀ is above brown with narrower orange marginal bands. Expanse of wings: 25 to 32 mm. From San Bernardino (California).

L. saepiolus Bsd. (= *achaja* Behr, *rufescens* Bsd.) (144 b). The ♂ has above a green lustre, a lighter *saepiolus*. blue and a more broadly smoky border and apex, the ♀ is tinged green-blue towards the base with orange marginal lunae on the hindwing. The under surface is lighter, more brownish, marked like *daedalus*, but on an average with smaller spots, at the border the orange colour is mostly absent. Pacific States, Rocky Mountains.

L. amica Edw. (= *orbitulus* Scudd. nec *Prun.*) (144 b) is above more silvery blue, at the margin *amica*. brownish with a narrow straight discal streak of the forewing and white fringes. The under surface is lustrous grey-white with rows of small spots; on the hindwing the postdiscal band runs almost straight, the small brownish submarginal lunae are sometimes obsolete. From the Mackenzie River. Expanse of wings: 27 mm.

L. pembina Edw. is closely allied to *pheres* (144 c), of a darker violet-blue, with the discal streak *pembina*. of the preceding, the ♀ brown, towards the base bluish. The under surface is light brown-grey, towards the base dusted blackish with the same arrangement of spots as in the following species, but on the hindwing with more distinct submarginal dark dots ending in the anal angle with a dark diffuse spot; also in the costal-marginal area there are two black, white-ringed, small spots. British North America (Lake Winnipeg).

L. pheres Bsd. (144 c) is larger, lighter blue than *pembina*, without the discal streak. The under *pheres*. surface is characterized by the white diffuse spots on the light brownish-grey surface of the hindwing; — the f. **evius** Bsd. is an alpine form from the Rocky Mountains. — Pacific States. *evius*.

L. phileros Bsd. (= *helios* Edw.) is in its exterior very much like *icarioides* (144 b); it is smaller, *phileros*. above more violet-blue, beneath of a purer ashy-grey; the white discal spot of the hindwing has the shape of a heart like in the European *icarus*. The ♀ is brown, with a blue-violet tinge towards the base and with small, obsolete, red-yellow marginal spots of the hindwing. California, Arizona.

L. ardea Edw. The ♂ is above violet-blue to grey-blue with a very narrow dark marginal band in *ardea*. the forewing and a dark marginal line in the hindwing, as well as white fringes. Under surface fawn-coloured the base of the hindwing bluish. The forewing exhibits a large, reniform, black, white-bordered discal spot, an incomplete postdiscal row of 4 spots and traces of a submarginal row of small brown lunae; on the transverse vein of the hindwing a large white diffuse spot, the postdiscal spots are absent altogether. Expanse of wing : 24 mm. Nevada.

L. kodiak Edw. (144 c) is a smaller species, the ♂ above dark blue, with a very narrow black *kodiak*. border, the ♀ of a plain dark brown. Beneath the forewings are grey-brown with the usual though small eye-spots; the hindwings are extensively tinged greenish, likewise with minute eye-spots; the proximal submarginal row consists of small angular spots in the openings of which the distal punctiform spots are placed. Known only from Alaska.

L. mela Streck. is another species having been inserted in this subgenus. It has not become known *mela*. to us, and its diagnose in the supplement of a North American special work is not available for us at present. It is said to occur in Colorado and British Colombia.

3. Subgenus: **Nomiades** Hbn.

L. xerxes Bsd. (144 c). The ♂ is above dusted with dark blue; also the ♀, but less, on the under surface *xerxes*. very easily recognizable by the large white spots which may occasionally be very finely pupilled black. From California.

antiacis. **L. antiacis** Bsd. (= *polyphemus* Bsd., *orcus* Edw.) (144 c) is in the ♂ quite light violet-blue with a narrow black border, the ♀ dull brown-grey, with a blue tinge towards the base, beneath light grey, on the hindwings somewhat more brownish; the spots show the same arrangement as in *xerxes*, but they are thickly pupilled black, particularly on the forewings; there are no submarginal spots at all. California, Nevada, and Arizona. — The form: *mertila* Edw. (144 d) has less thickly black-pupilled spots and more intensely greenish bases of the hindwings, whereby it comes nearer to *xerxes*. — f. *behrii* Edw. (144 c) is distinguished by its much darker grey-brown under surface.

couperii. **L. couperii** Grt. (= *pembina* Streck, nec Edw., *afra* Edw.) (144 d) is perhaps only a northern form of the preceding from New Foundland and Labrador; above almost the same, beneath dark brown-grey, the spots arranged the same, but nearly all white, only slightly black-pupilled, particularly on the hindwing. Fringes grey-brown, in *antiacis* white.

lygdamas. **L. lygdamas** Dbl. (144 d) is considerably smaller, above much lighter silvery blue, in the ♀ darker, towards the margin smoky, with a dark cell-spot. The under surface is light brown with thick, black, white-ringed spots arranged like in the preceding species and a pair of small spots in the middle of the cell on the forewing. Sonora, Atlantic States. — The form: *oro* Scudd. (144 d) is larger, beneath quite light grey, without a brown tint, towards the base somewhat bluish. It flies in Colorado, California and New Mexico.

4. Subgenus: **Phaedrotes** Scudd.

sagittigera. **L. sagittigera** Fldr. (= *catalina* Reak., *lorquinii* Behr, *rahae* Bsd., *viaca* Edw., *daunia* Edw.) (144 d) is a most variable species, mostly rather light blue, towards the margin more or less dark smoky with white-speckled fringes. Beneath grey-brown, dusted with a chalky white alternating more or less conspicuously particularly on the hindwing in the cell and before the submarginal spots. In the Rocky Mountains and California.

speciosa. **L. speciosa** Edw. (144 d) is a very small species, of a delicate light blue, in the ♀ broadly bordered with a brownish grey. Beneath so very much strewn with white that almost only the inner-marginal half of the forewing remains brown; the spots of the hindwing are very small, the submarginal spots are almost entirely absent. From South California.

5. Subgenus: **Philotes** Scudd.

sonorensis. **L. sonorensis** Fldr. (= *regia* Bsd.) (144 e) is unmistakable by the red-spotted, silvery blue forewings. Distributed from California to North Mexico.

6. Subgenus: **Agriades** Hbn.

podarce. **L. podarce** Fldr. (= *tehama* Reak., *cilla* Behr, *nestos* Bsd., *orbitulus* Streck.) (144 e). The ♂ is above grey-blue, towards the margin darkened, and in the disc lighter, here with dark cell-streaks, before the border of the hindwing with darker, small lunae. The under surface is dull grey-brown with the usual small eye-spots and a large white cell-spot of the hindwing. In the darker ♀ the cell-spot of the forewing is above surrounded by reddish-yellow. At loftier altitudes of California, Nevada and Colorado.

aquilo. **L. aquilo** Bsd. (= *franklinii* Curtis) (144 e) replaces the eastern *orbitulus* in Arctic America, like the following does in less northern latitudes. Very small and dark blue-grey, particularly also the under surface very dark brown with large white, only feebly and finely black-pupilled spots.

rustica. **L. rustica** Edw. (144 f) is almost the same species as the preceding, and according to COURVOISIER, the name has to replace the palaearctic denomination of *orbitulus* Prun.; by one third larger, and lighter blue than *aquilo*, beneath light grey with purely white spots. From Colorado and British America.

7. Subgenus: **Rusticus** Hbn.

enoptes. **L. enoptes** Bsd. (144 e). Above blue, the ♀ brown, more or less suffused with blue, with or without an orange marginal band of the hindwing. The fringes white-speckled. The under surface is light blue-grey with the usual spots, between the submarginal spots of the hindwing small orange spots. Pacific States.

glauccon. **L. glauccon** Edw. (144 f) has a somewhat broader black border of the wings than *enoptes*, and on the hindwings there appear above dark marginal lunae. The under surface resembles that of the preceding, and is perhaps on an average more strongly spotted black. Colorado, California.

battoides. **L. battoides** Behr (144 f) is of a more delicate and lighter blue than the preceding, with a distinctly diaphanous orange marginal band of the hindwing and before it small dark crescentiform spots. Beneath brown-grey with much larger, more square spots arranged in the same way as in *enoptes*. California, Arizona, Colorado.

L. shasta *Edw.* (= *zelmira* *Fldr.*, *calchas* *Behr*, *nivium* *Bsd.*, *lupini* *Behr*; *minnehaha* *Scudd.*) (144 f). *shasta*. Above violet-blue, in the ♀ extensively brown, with dark submarginal lunae, very distinct black cell-streaks, and in the ♀ with small orange marginal spots behind them. Beneath dirty grey with the usual rows of spots and small orange marginal spots; the distal submarginal row of spots is proximally silvery blue-green. Pacific States and Rocky Mountains.

L. melissa *Edw.* (144 f) is on an average larger than the preceding, in the brown ♀ above with broad orange marginal bands, behind which there are black marginal spots. Beneath light brownish grey with oblong orange marginal spots on both wings. From the Rocky Mountains.

L. scudderi *Edw.* (144 f). The ♂ does not differ above from *melissa*, the ♀ is darker, the orange marginal bands reduced to narrow, small crescentiform spots on the hindwings, the under surface is whiter, the eye-spots, orange marginal spots and small metallic spots all very much smaller. The larva lives on Lupini and other Papilionaceae. Atlantic States, common.

L. lotis *Lintn.* (144 f) is larger, the ♂ violet-blue with a very narrow black border, the ♀ above unicolorously brown, beneath as light as the preceding, perhaps a shade more brownish, with particularly reduced submarginal spots without any orange between. From California.

L. acmon *Dbl. & Hew.* (= *antaegon* *Bsd.*) (144 g). Very easily recognizable by the broad orange marginal band of the hindwing in which there are black submarginal spots, both in the brown ♀ being dusted blue towards the base, and in the lilac-blue ♂. Beneath marked like *melissa*, only of a somewhat lighter tinge and with a coherent orange band between the submarginal rows of spots. Pacific States and Rocky Mountains, to the south as far as Mexico, where it flies in the surroundings of the capital. — In the form **emigdionis** *Grinnell* (= *melimona* *Wright*) (144 g) the orange bands of the hindwings are above still broader and proximally faded. — subsp. **monticola** *Clem.* is above more silvery blue, beneath marked with thicker spots on an ashy-grey ground strewn with bluish. The ♀ is above strewn with a much brighter blue as far as almost to the border, the red band of the hindwing occupies almost one third of the hindwing; the under surface is more brownish. From Pasadena (California). — f. **neurona** *Skinner*, described only according to female specimens, resembles typical *acmon* from which it differs above by orange ribs terminating broader into the margin, also the costal margin is sometimes orange. From San Bernardino (California). — f. **chlorina** *Skinner* (144 g) I can likewise only take to be an aberrative ♀ of *acmon*, with a much broader orange border of the hindwing, which, however, does not appear proximally faded as in *emigdionis*, but distinct. California.

L. aster *Edw.* (144 g, h) is smaller than the preceding, above light blue like *enoptes*, the ♀ dull blue-grey, instead of the orange marginal band there are faint blue small lunae bordering on the black marginal spots. Beneath very light, the spots small, the submarginal spots more or less obsolete without any orange between. Known only from New Foundland.

L. yukona *Holl.* has remained unknown to me, it may belong near here. The wings are above in the ♂ dark violet-blue, with a fine brown marginal line and white fringes, in the ♀ black-brown, towards the base with a blue tinge. Beneath dark ashy-grey, towards the base dusted blue-grey, marked like the others; a characteristic mark is the 6th spot of the postdiscal row, counted from the costal margin, being double on both wings, only on the hindwing removed very far inward; between the 2 rows of marginal spots there is no orange except the space between the median veins of the hindwing; the subterminal row consists of small sagittate spots the points of which show towards the base. Expanse of wings: 22 to 24 mm. From North East Alasca, captured between the 20th and 24th of July.

L. annetta *Mead.* (144 g). Above light blue, the ♀ still much lighter, towards the margin almost whitish, on the hindwings with small black marginal spots. Beneath coloured and marked like *scudderi*. Utah.

L. anna *Edw.* (= *cajona* *Reak.*, *argyrotoxis* *Behr*, *philemon* *Bsd.*) (144 h) resembles *melissa* (144 f) above, but it is considerably larger; also the under surface is extremely similar to that of *melissa*, but all the spots somewhat smaller and finer, also the small orange marginal spots smaller. Pacific States, Colorado.

L. cogina *Schaus.* I am unable to judge whether this species and the 2 following, having remained unknown to me in nature, belong to the real *Lycaena* or to one of the following genera. The description runs as follows: In the ♂ the forewings are lilac-white, towards the base strewn with black; the costal margin, apex and distal margin are broadly grey-black; hindwings lilac-white, at the base strewn with black scales; costal margin broadly dark grey; a black marginal line, dark marginal spots between the veins, and before them dark triangular shades. Under surface grey-white with a dark marginal line and dark triangular marginal spots. The forewings exhibit a dark spot at the cell-end, a postdiscal row of dark grey spots bordered with white, and behind them dark diffuse spots between the veins, before the border a series of dark lunae. On the hindwings the spots are bordered with a pure white; two dark costal-marginal spots, in the basal area 3 spots: one in the

cell, one below it, and one at the proximal margin; at the cell-end a streak-like spot, behind it a very indistinct macular series, followed by irregular grey shades; before the border dark angular streaks. Expanse of wings: 22 mm. Castro (Paraná).

griqua. **L. griqua** Schs. has olive-grey wings, dark discal streaks and a dark distal margin, in front of which the markings beneath show indistinctly through; fringes white, speckled grey. The under surface reddish-yellow with an olive tinge, the spots black, bordered with an isabel-colour; a dark marginal line, small dark grey marginal spots, the latter more distinct on the forewings; here there is a black spot at the cell-end, behind it a series of larger black spots; on the hindwing 2 small basal spots at the proximal margin, then a row of 4 black spots, a light spot at the cell-end, behind them a row of 7 black spots, the third from the costal margin being placed the farthest towards the distal margin. Expanse of wings: 20 mm. Castro (Paraná).

ruberrothi. **L. ruberrothi** Weeks. Body above black, beneath white. Forewing above light brown-black, in the basal area black, marginal line and veins darker; hindwing above like the forewing, at the border a series of black spots margined with a light brown, the one above the lower submedian vein being the most prominent. Forewing beneath light brown, in the basal half strewn with white scales; at the border there are lighter moon-spots indicated; in the hindwing beneath the white scaling is extended over the whole surface of the wing. Expanse of wings: 18 to 19 mm. — Bolivia (Sicasica). Perhaps better to be placed to *Itylos* beside *moza* and *inconspicua*.

10. Genus: **Cyaniris** Dalm.

The species of this genus are distinguished by much more delicate, comparatively somewhat broader wings and longer, more pointed palpi projecting far beyond the frons; their hairing is longer, too, and not so dense.

ladon. **C. ladon** Cr. (= *pseudargiolus* Bsd. and Lec., *argiolus* Smith and Abb., *intermedia* Streck.) (144 h) is an extremely variable species being most widely distributed from Alaska and Anticosti to Panama. Above delicately milky blue with a slight violet tinge, on the hindwings almost whitish, in the ♀ above very broadly margined with black, often also on the forewings brightened up by whitish towards the margin. This is the typical summer-form, the under surface of which is white with small fine, black-grey punctiform spots. — In early spring several forms fly together, which are generally somewhat smaller and exhibit beneath more diffuse and confluent macular markings, such as: **lucia** Ky. (144 h) with a brown spot in the disc of the hindwing beneath; **marginata** Edw. (144 h) with broad, brown-grey margins beneath. — In contrast with it: f. **violacea** Edw. (144 h) has a clear and not confluent marking beneath. — In West Virginia and Colorado there flies a form that is quite black above: **nigra** Edw. (144 i). — f. **cinerea** Edw. may be a transition to it. — f. **arizonensis** Edw. has in the ♀ considerably broader margins of the wings, the colouring being paler. — f. **neglecta** Edw. is another form flying in summer with a much more prominent and clearer marking beneath and of a smaller size. — In South Arizona f. **piasus** Bsd. flies with a much darker violet-blue, unmarked colouring above; beneath the spots are more indistinct. — f. **echo** Edw. is a large, quite pale, almost grey-white form from South California. — f. **gozora** Bsd. (144 i) is the southernmost form from Mexico and Central America to Panama; it is above of a deeper, more lilac colour with white discal spots between the median veins of the forewings, and a broad white, grey-veined distal half of the costal area of the hindwing. — The larva is very polyphagous.

11. Genus: **Everes** Hbn.

Distinguished by anastomosis of the uppermost subcostal vein with the costal vein. The wings are narrower, the palpi slender and pointed, the two first joints covered with dense, soft, porrect hair.

amyntula. **E. amyntula** Bsd. (144 i). This and the following species are both extremely alike and have, therefore, led to disagreements of opinion. We here state their general differences, according to the excellent examinations of BETHUNE-BAKER, by which they are easily discernible, as there are no absolutely sure marks to be stated. *Amyntula* is generally much larger, with decidedly broader wings, with a sharper apex and a straighter margin. Above the marginal line is fine, black. The under surface is whitish, the spots of the forewings short diffuse spots, scarcely encircled by white, the submarginal spots obsolete, also on the hindwings all the spots are generally more obsolete. — In f. **herrii** Grinnell which, however, coincides with BOISDUVAL's type according to BAKER, the black border of the wings is broader, the marking beneath much more intense, and on the hindwing there are only two small orange spots at the margin instead of the usual 5. Pacific States. Of this species only one generation is known. The larva lives on *Astragalus*.

comyntas. **E. comyntas** Godt. (144 i) is generally smaller, with narrower, rounder wings, with a bent distal margin. Above the marginal line is broader, more brown-black. The under surface is decidedly greyer, the

spots appear as more clearly prominent, white-ringed eye-spots, the submarginal spots and all the spots of the hindwing are always distinct. In southern specimens the blue colour increases at the bases of the wings, in the ♀ above. The species is widely distributed from Canada to the south through Mexico, Guatemala, Honduras, Nicaragua as far as Costa Rica, in 3 or 4 generations. — The larva is brown or green, very variable, and lives on the most different Papilionaceae.

E. tulliola G. & S. (144 i) is a very much deviating, small delicate species. Above light blue with *tulliola*, a broad, brown-grey distal margin of the forewing and a narrower one of the hindwing. Beneath light grey with the usual postdiscal series of blackish, white-ringed eye-spots and cell-spot; in the middle of the cell there is besides a double, black spot which is only single or may be entirely absent in specimens from more southern habitats, and at the costal margin above the said spots and the discal streak there is one black, white-ringed punctiform spot each; before the brownish-grey marginal triangles in the white ground a series of angular spots appearing as a notched line. The hindwings are marked in the same way. Occurring from Mexico through Guatemala, Venezuela, Colombia as far as East and South Brazil.

In addition we wish to state that two species, hitherto inserted in *Everes* and reported to originate from California: *monica* Reak. and *tejuia* Reak. have been identified by Dr. SKINNER, on comparing the types, as the Chinese *Euchrysops cnejus* resp. *Catochrysops strabo*.

12. Genus: **Hemiargus** Hbn.

Scarcely different from the real *Lycaena*; the scaling is more delicate and thinner, the colouring mostly a more lustreless violet-blue; beneath the hindwings exhibit at the anal angle 2 or 3 black, small eye-spots being pupilled and encircled green silvery.

H. isola Reak. (= *alce* Edw.) (144 i, k). The ♂ is above violet-blue, the ♀ brown, towards the base *isola*, more or less tinged blue, on the hindwings in the anal area with 1 or 2 black marginal spots. The under surface is ashy-grey, the hindwings mostly more brownish, on the forewing, with a postdiscal row of large black, white-ringed spots, all the other spots except 2 black costal-marginal spots on the hindwing are small and brownish; on the hindwing there are behind a whitish submarginal band 2 black anal spots with green-silvery pupils and encircled by somewhat reddish-yellow, the proximal one being mostly divided into two very small ones. From Texas to Mexico. — **nyagora** Bsd. I can only take to be an insignificant form, in which the white submarginal *nyagora*, band is absent on the darker under surface of the hindwing.

H. gyas Edw. is very much alike, above lighter violet-blue, otherwise the same. Beneath light *gyas*, brown with a whitish hue, with the same markings, but without the whitish submarginal band, and the two anal spots are plainly blackish. Arizona. Expanse of wings: 23 mm.

H. cyna Edw., based upon a ♀, has above on a purple blue ground a broadly darkened brown margin *cyna*, and apex, and a fine discal streak; on the hindwing the anal spot is absent. The under surface is tawny, dusted whitish, the large black spots on the forewings in the preceding are here brown, the two upper ones smaller and placed inwards. Texas. Expanse of wings: 22 mm.

H. zachaeina Btlr. (144 k) differs from *isola* by its deeper purple-blue above and like in *cyna* a plain *zachaeina*, brown macular band on the lighter under surface of the forewing, the spots being smaller and narrower; only 2 costal-marginal spots and one basal spot of the hindwing are jet-black. Florida, Antilles, Cuba, Jamaica, Dominica, Central America, Colombia as far as South Brazil.

H. hanno Stoll. (= *antibubastus* Hbn., *hamo* Luc., *pseudoptilete* Bsd. & Lec., *astenidia* Bsd., *filenus* *hanno*, Poey.) (144 k) forms about the middle between *isola* and *zachaeina*, above not different from *isola*, the blue colour perhaps somewhat duller. The under surface is brown-grey, marked like *isola*, but the postdiscal row of spots is not jet-black, but brown like in *zachaeina*, the spots smaller, the uppermost placed far inwards. On the hindwing the whitish marginal band is absent, and there is only one small black anal spot with a silvery green pupil and encircled by a faintly rusty-yellow ring; beside this spot there are in the basal area 3 and at the costal margin 1 prominent, jet-black, small eye-spots. Mexico to Colombia (Bogotá). Specimens from the latter habitat are beneath much darker and more monotonously brown: **bogotana** f. nov. *bogotana*,

H. ramon Dogn. resembles above small specimens of *hanno*. The colour beneath is lighter ashy-grey, *ramon*, towards the margin strewn with blue atoms, the marking like in *hanno*; on the hindwing only in the basal area the 4 jet-black, small eye-spots are prominent, all the others are brown-grey; at the border there are here 4 black small spots pupilled metallic green. Described from Ecuador (Loja). Expanse of wings: 22 to 25 mm.

H. martha Dogn. is still smaller, above with a somewhat broader black border and a series of black *martha*, marginal dots on the hindwing. Beneath like *ramon*; but on the hindwing in the middle with a large white transverse spot bordered with brown beneath; the 4 marginal eye-spots are in a brown ground. Expanse of the wings: 19 to 22 mm. Ecuador (Loja).

ammon. **H. ammon** *Luc.* (144 k) is likewise similar, but easily discernible by two black anal spots above, the proximal one of which mostly exhibits towards the base an orange-red spot. Beneath more purely white and black-grey, the hindwings all white with grey spots, the two anal spots jet-black, bordered with a bright silvery blue, and those between the median veins proximally spotted broadly orange-red. Florida, Cuba, South America. — f. **dominica** *Möschl.* seems to be only an insignificant form in which, on the under surface of the hindwing, the 3 small spots in the basal area are not prominently jet-black. Dominica.

13. Genus: **Brephidium** *Scudd.*

The costal vein is entirely coalescent with the uppermost subcostal. Very small, delicate insects with comparatively narrow wings with rounded apices. Beneath the hindwings exhibit up to 7 metallic-pupilled marginal eye-spots, of which mostly only 4 are fully developed.

isophthal-
ma. **B. isophthalma** *H.-Schäff.* (= *pseudofea* *Morris.*) (144 k). Above brown with a brass or copper reflection, on the hindwing with a marginal row of blackish spots being pupilled thickly black and outside silvery on the red-brown under surface. Fringes one-coloured grey-brown. Gulf States, Antilles.

exilis. **B. exilis** *Bsd.* (= *fea* *Edw.*) (144 k) is the same, but smaller, above mostly with a more intense brass lustre, and broad white fringes at the proximal angle and in the apical half of the forewing; on the under surface, before the black, marginal, macular series, the ground is more distinctly white. From the Gulf States through Mexico and Central America as far as Venezuela.

14. Genus: **Leptotes** *Scudd.*

Very near to *Hemiargus*, but still more delicately built; the costal and uppermost subcostal veins run rather closely beside each other without coalescing. The hindwings beneath exhibit at the anal angle 2 small black eye-spots with metallic blue pupils.

cassius. **L. cassius** *Cr.* (144 k, l). An extremely common species widely distributed in the south; the ♂ above violet with diaphanous spots beneath, the hindwings are white, and at the costal margin and border lilac variable in extent. Beneath white with numerous brown macular bands, 2 before the border close together, the distal one consisting of punctiform spots, the proximal one of crescents, the 2 spots being placed the nearest to the anal angle jet-black, bordered with silvery blue. The ♀ is white also above, towards the base of a silvery blue opalescence with black-brown spots, costal and distal margins. From Mexico through the whole of Central America as far as Colombia, South Brazil, also in Cuba, Jamaica, Hayti, and Dominica; flies up to 5000 ft.

theonus. **L. theonus** *Luc.* (= *cassius* *Morr.* nec *Cr.*) (144 l) is probably only a smaller northern and insular form of *cassius*. The ♂ is lavender-blue with somewhat broader dark margins; the ♀ white, on the forewings somewhat more extensively suffused with blue, without the intense black spotting of *cassius*. Beneath the white is more reduced, the macular bands much darker; the anal spots of the hindwings are above and beneath very thickly black.

marina. **L. marina** *Reak.* (= *cassioides* *Bsd.*, *pirithous* *Godt.*, *floridensis* *Morr.*) (144 l) is above of a duller and darker lilac-blue colour than the preceding, with a black border narrowing to a line and very diaphanous marking beneath; the ♀ is intensely smoky brown-grey on the white ground, towards the base with a blue lustre, somewhat more strongly spotted than the ♂. The under surface is much darker by the white being very much confined as far as the proximal margin; the anal spots are distinctly encircled by a rusty yellow. Distributed from Texas, Arizona, California through Mexico as far as Guatemala. — The slightly differing f. **cassidula** *Bsd.* has purely white fringes, and in the anal area of the hindwing beneath the eye-spots are not alike, the proximal one very small or entirely absent. Described from Honduras.

striata. **L. striata** *Edw.* was described from San Antonio in an American forestry magazine of 1877 not available to me.

andicola. **L. andicola** *G. & S.* is almost twice as large as *marina*, with a sharp apex of the wings, above violet-blue with dirty silky-white fringes, beneath grey-brown with small, darker spots edged with white; before the margin of the hindwing with a white band and 3 reddish-yellow, small anal spots with black pupils and strewn silvery. Expanse of wings: 40 mm. Discovered by EDW. WHYMPER in the Andes between 7500 and 12 000 feet.

callanga. **L. callanga** *Dyar* (144 l) is somewhat larger than *marina*, above reddish violet-blue with a silky gloss and a very fine brownish border. The fringes of the forewing are grey-white, at the ends of the veins speckled somewhat darker, those of the hindwings purely white. On the under surface the forewings are light red-brownish with somewhat darker spots encircled by a whitish colour; before the discal spot there is another spot in the middle of the cell; the spot of the postdiscal row situate between the lower radial veins has a very oblique position and projects far towards the margin, which in its whitish ground contains marginal and subterminal rows of purely grey spots. Hindwings more grey-brownish, likewise only dull-spotted, with a purely white band between the postdiscal and subterminal rows of spots, at the anal angle 2 very small black dots encircled by silvery green. Peru (Cuzco). In my opinion the species may be identical with the following.

L. ochsenheimeri Godt. Whether this species unknown to me is to be placed here, I cannot decide; it at any rate seems to me to be allied to *callanga*. Above blue-violet with a brown margin and white-speckled fringes. Beneath the disc of the forewing is red-yellow with some small light yellow ring-spots, a white undulate line before the apex and black marginal dots. The hindwings are beneath of a dirty brownish; in the basal area there are grey rings, behind the middle an undulate snow-white band and 5 small black marginal spots, at the anal angle 3 small spots strewn with a golden green. Expanse a little more than an inch. Described from the Antilles, though doubtful. *ochsenheimeri*.

15. Genus: **Itelos** *gen. nov.*

Anatomically hardly separable from *Lycaena*, but the total impression of these small insects flying only in Tropical America, mostly at great altitudes, is so characteristic that the separation is justified. The hairing of the body is stronger, particularly the palpi show a much longer, somewhat porrect, beard-like hairing on the underside, whereas laterally they are covered with broad scales. Costal and subcostal vein of the forewing run separately. The fringes are uncommonly long, mostly speckled very conspicuously; the colour above is a metallic blue of a very intense mother-of-pearl gloss, in other species silvery or coppery bronze are predominant; the under surface of the hindwings mostly shows conspicuous silvery-white macular marking or peculiarly brown serpentine lines. As to the synonymy this group offers great difficulties, because there are a lot of obvious manuscript names, but no descriptions.

I. pelorias Weym. (144 m) I only know from the description and figure, it must be extremely allied to the following; the brown upper surface exhibits a silvery grey-blue lustre only in the basal area, the fringes are sharply speckled brown and white. Beneath like *pacis*, but the brown transverse markings of the hindwings, having moreover the same course, seem to be darker black-brown and more distinct; in the marginal area there are no markings whatever. Described according to a ♂ from Bolivia (Sajama) between 3600 and 4600 m. Length of forewings: 10 mm. The specimen denoted as ♂, however, may anyhow be ♀ of the following form, which would then become synonymous.

I. pacis Stgr. i. l. (144 l, m) is above extensively violet-blue with a purple lustre, towards the margin brown with distinctly white-speckled fringes, in the ♀ only in the basal half silvery blue-violet, at the border much broader reddish-brown. Beneath reddish-brown, on the forewing with a discal spot and a series of post-discal spots, in the marginal area indistinct, double, darker, small lunular spots in a ground dusted whitish; the hindwings, on a ground being more intensely dusted whitish, show irregularly torn, dark brown spots in the basal area and a more distinct transverse band from the costal angle to the middle of the proximal angle, projecting far towards the margin between the lower radial veins, and below it with a large silvery white spot; another white patch is situated at the costal margin between a basal spot and the beginning of the transverse band. Marginal markings indicated like on the forewings, between the median veins more distinct. Peru (Cuzco).

I. koá Drc. (144 m) is above duller and darker, beneath somewhat lighter; on the forewings the spots are not darker than the ground, their white edges appear as white, coherent undulate lines; on the hindwing there is a complete white longitudinal ray in the costal-marginal area, traversing the dark transverse band, the white spot in the anal area is also larger and bifurcates towards the distal margin. Peru, Bolivia, apparently rare.

I. vapa Stgr. (144 m) approximates the preceding; it is above monotonously brown with broadly white-speckled fringes. The under surface is very much like that of *koá*, but much lighter; the silvery white costal-marginal stripe extends to the costal margin itself and in it there are about in the middle 3 small round spots of the pale brownish ground-colour; the white spot below the discocellular is much more extensive and almost reaches to the base. In Peru and the Bolivian Andes between 3 and 4000 m (Cuzco, La Paz, Huallatani, Cocapata).

I. ludicra Weym. (144 m). This species described according to but one specimen must likewise be closely allied to *koá* and *vapa*, the upper surface, however, is described to be light silvery blue as in our *Lyc. eros*, though with a much stronger lustre; the narrow brown distal margin gradually warms into the blue colour and is somewhat broader at the apex; at the cell-end there is a brown streak; the fringes are speckled brown and white. The under surface is light yellowish-brown, the macular bands recognizable only by their white bordering. The fringes are all white in the basal half, and speckled only in the distal half. On the hindwing the silvery-white costal-marginal stripe is distally broader, sending forth an off-branch on the subcostal vein. As the remainder of the brown transverse band of the preceding species there are a series of dark-brown crescentiform streaks bordered distally by white, from below the lower radial vein in the shape of a broad white band; at the proximal angle several small white spots, the one between the median veins with a black pupil. Length of forewings: 10 mm. Bolivia (Tacora), 3600 to 4600 m.

I. moza Stgr. is a somewhat larger species, above lustrous smoky-brown with an intense metallic lustre, distinguished by the unspeckled fringes being in the distal half dirty white, in the proximal half darker

brown than the surface of the wings; before the distal margin of the hindwing there are 3 to 5 blackish, small eye-spots with a light enclosure. The under surface is very similar to that of the following species, but below the discocellular of the hindwing a silvery white patch is more prominent. Bolivian Andes near Copacata and Huallatani (3 to 5000 m).

inconspicua. **I. inconspicua** *sp. nov.* (144 m) is smaller than the preceding, dull smoky brown with broadly white-speckled fringes, without any lustre; the hindwings above without any small marginal spots. Beneath dull yellowish-brown, the postdiscal row composed of minute, round, separate spots surrounded by white; a double submarginal row of spots in a whitish ground is very distinct. The hindwings are very much strewn with white, in the basal and inner-marginal areas with a silvery blue-grey lustre, as well as in the basal area of the forewing. Before the middle 3, behind it 7 or 8 small round spots of the ground-colour, margined by a somewhat darker colour and encircled by white, form an irregularly curved row; before the dull grey-brownish marginal triangles there is a regular series of high, pointed arches bordered by white on both sides. Cuzco (Peru) at an altitude of 3600 m.

titicaca. **I. titicaca** *Weym.* (144 m), presumably the smallest species, and the following belong into a somewhat deviating group. The shape of the wings is much longer and more pointed. Above lustrous violet-blue, like *Lycaena icarus*, with a narrow brown distal margin and long dirty white fringes. Beneath lustrous light yellowish-brown, the hindwings white-grey, towards the costal margin with a dark brown longitudinal line, below it 2 brown transverse lines from the costal margin to the proximal margin, being inwardly curved in the middle; near the distal margin several brown sagittate spots. Based upon 3 specimens from Lake Titicaca and Sajama (Bolivia), from an altitude of 3600 to 4600 m. Length of forewings: 7 mm.

speciosa. **I. speciosa** *Stgr.* (144 n). In the ♂ the upper surface is blue-violet, the margins brown, all with an extremely intense bronze lustre, suffused as if polished; the ♀ is more extensively brown, only at the bases of the wings with a slight silvery grey-blue tinge. The fringes are speckled white. The forewings are beneath dull brownish, with a white-grey tinge towards the margin, the hindwings all white-grey with 2 sinuate dark brown transverse lines the proximal one of which turns round towards the base below the costal margin and sends a pointed continuation towards the base on the median. Moreover these lines seem to vary very much, Peru and Bolivia at an altitude of 4 to 5000 m. (Cuzco, Huallatani).

16. Genus: **Scolitantides** *Hbn.*

This name of the genus having been established by HÜBNER for *Lycaena hylas* *Schiff* (nec *Esp.*) = *baton* *Bergstr.* has been improperly used since, for a small group of *Lycaena* from the southernmost corner of America, where we may leave it for the present, as the group in itself is very homogeneous, although a separation from *Lycaena* is scarcely a point at issue. In its exterior it partly differs by an orange-red colouring above, which is repeated in all the species in the disc of the forewing beneath. In the colour and scheme of markings the small animals also show some resemblance to the *Chrysophanini*, but on account of the shape of the hindwings, which are the longest between the radial veins, they must better be placed here. About half a dozen species, mostly from Chile, have become known hitherto.

chilensis. **S. chilensis** *Blch.* (= *atahualpa* *Wallengr.*) (144 n) is above black-brown with an orange-red disc of the forewing and pale, on the forewings almost white, small submarginal lunae; the one between the median veins of the hindwings is larger, orange, distally black-pupilled. Under surface pale yellowish-grey, in the disc of the forewing orange with a strongly curved postdiscal row of small black spots, behind it a row of more grey spots. Hindwing densely dusted grey with a cordiform white discal spot and behind it a strongly curved row of ocelli, also in the basal area yet 3 eye-spots. Chile.

plumbea. **S. plumbea** *Btlr.* differs above from the following species by its lustrous blue-grey colour with a broad dark distal margin and veins. Fringes broadly white, spotted black. Beneath likewise similar to *collina*, but deviating by its lighter colouring, the fringes being speckled black and white, the basal half of the hindwing being very much intermixed with white and the distal half almost entirely white. Chile.

collina. **S. collina** *Phil.* (= *lyrnessa* *Hew.*) is above lustrous blue with a black margin and white-speckled fringes. Beneath the disc of the forewing is orange with a curved postdiscal row of black spots, the border grey with dark marginal spots bordered by white. The hindwings are grey marbled with a transverse band and one black longitudinal spot each at the costal margin and proximal margin. Santiago de Chile.

endymion. **S. endymion** *Blch.* (= *sybilla* *Ky.*) deviates from *collina* by small antemarginal black spots above. Beneath the disc of the forewing is yellow-grey, towards the margin lighter, with a black cell-end streak, behind it 6 large black spots and an antemarginal double row of small diffuse spots, all of which have white rings. The hindwings are grey, marked as in *chilensis*, the antemarginal line composed of angular streaks. Chile (Coquimbo).

faga. **S. faga** *Dogn.* (144 n). This small species was described as *Thecla*, later on placed to *Scolitantides* by DRUCE, with which, however, it does not harmonise either. The shape of the wings is greatly distinguished

by the distal margin contiguous to the proximal margin in an almost rectangular line; the costal margin of the hindwing is somewhat concavely indented, the hindwings exhibit two very short small tails. Above brown with a slight purple lustre, at the anal angle of the hindwing with 2 minute black dots. The ♀ is somewhat larger, with a more intense copper lustre. Beneath the forewings are orange in the disc, towards the margin with two grey-brownish macular stripes; the hindwings are dusty grey with numerous blurred, whitish, small spots and a distinct white transverse band running straight from the costal angle to the anal angle. Ecuador, Peru

S. sylphis *sp. nov.* (144 n) I can only describe according to the only ♀ before me from the Collection *sylphis*. FASSL: the shape is the same as in the preceding species, but the colour greatly deviates above from the copper-brown ♀ of *faga*: suffused with a bright blue violet, with orange-red antemarginal macular bands on both wings. Beneath in the disc likewise red-yellow, the 2 marginal bands consist of distinct black small spots with white rings, on the hindwing the straight whitish transverse band is absent. Cuzco (Peru).

S. excisicosta *Dyar* differs from *faga* above by white-speckled fringes, the costal margin of the hindwing *excisicosta*. being flatly concave like in *faga*, the apex projecting roundish, on the hindwing analwards 3 minute black spots, proximally feeble, whitish, small lunae. Beneath the forewings are likewise orange, at the costal margin and distally grey with 2 rows of dull small submarginal spots surrounded by whitish; hindwings almost grey with a whitish submarginal band and very small, dull basal and discal spots; the 3 small anal spots have golden pupils. Peru (Cotahuasi, Chuquibamba) in October.

Corrections and Additions.

P. 757, line 3 from below, after *catadupa* insert:

Th. gauna *Bsd.* shaped like the preceding, above azure with a black apex of the forewing and a jet- *gauna*. black stigma. Beneath ashy-grey with 2 obsolete undulate transverse bands and an interrupted submarginal line. Costa Rica.

P. 760, line 20 from above, after *bolima* insert:

Th. muela *Dyar* has the same shape of wings, only on the hindwing it has a more projecting *muela*. anal angle and a less projecting small tail on the lower median vein. Above grey-brown, the basal areas of both wings towards the proximal margins with a light blue tinge. Beneath very much like the preceding, the basal area of the forewing darker than the marginal area, the apex more olive-yellowish; on the hindwing the two colours are sharply separated by a line being interrupted in the cell; the olive-yellowish distal area is traversed by a faintly darker macular line. Peru.

P. 760, line 29 from above: to *anosma* place: **oribata** *Weymer*.

oribata.

P. 766, ,, 9 ,, : after *janthina* insert:

Th. janthodonia *Dyar*. Forewings black, below the cell for two thirds dark metallic blue, like the *janthodonia*. whole hindwings. Beneath dark slate-grey, marked bluish-white like the preceding; the area between the anal spots is not green, but blue, the spot of the tail with a red pupil. Expanse of wings: 25 mm. Vera Cruz.

P. 766, line 9 from below: cancel *bianca* *Mschlr.*

P. 767, ,, 17 ,, above: to *arindela* add: f. **rinde** *Dyar* is beneath brownish ashy-grey, on the *rinde*. forewing with but one postmedian band from the costal margin to the lower median vein; the subterminal band of the hindwing dusted silvery. West Mexico (Sierra de Guerrero).

P. 769, line 10 from below, to *cambes* add: (= *syvix* *Dyar*).

P. 771, ,, 27 ,, above, cancel *primnoxa* *Dyar* and add the name as synonymous to *elsa* *Hew.* (line 16 from above).

P. 771, line 10 from below, cancel *zenaida* *Dyar*.

P. 779, ,, 16 ,, above, for *deserta* insert: **sierrae** *Dyar*.

sierrae.

P. 780, ,, 9 ,, below, to *uterkudante* add: (= *elimes* *Dyar*).

P. 780, ,, 6 ,, , for *ostrinus* *Dree*. place: *bianca* *Mschlr.*

P. 783, ,, 22 ,, above, for *castrena* *Jones* place: *tella* *Schs.*

P. 783, ,, 18 ,, below, after *facuna* insert:

Th. muridosca *Dyar* is only as large as *nana*, above black, in the disc of the forewing and hindwing *muridosca*. violet-blue with the same scent-spot in the cell of the hindwing; anal angle hairy, without a tail. Beneath light blue-green, on the hindwing irregularly strewn with black scales, which are accumulated to small black spots between the veins in the distal area, the largest being situate between the median veins; the white, proximally black lunar line like in *nana* obsolete above the radial veins. Expanse of wings: 20 mm. Mexico (Jalapa).

P. 784, line 5 from above, after *semones* insert:

revenae. **Th. revenae** Dyar is above black with a dark blue lustre; beneath lustrous dark green with traces of an interrupted white line proximally bordered with black, on the hindwing; a black marginal line, fringes grey. Expanse of wings: 21 mm. Mexico (Misantla, Vera Cruz).

P. 784, line 19 from above: *Schausi*-group: the species mentioned here are genuine *Lycaenidae*, although they were placed to the *Erycinidae* by Dyar. For the group the name of the subgenus: **Ipidecla** Dyar is to be placed. Two new species are to be added:

miadora. **I. miadora** Dyar. Above unicolorously grey-black, towards the base on the forewing and almost on the whole hindwing spread over with a blue grey. Beneath blue-grey, with jet-black veins, with one orange-red basal spot each at the costal margins of the fore- and hindwings. Expanse of wings: 22 mm. West Mexico (Guerrero).

monenopteron. **I. monenopteron** Dyar (144 n) is similar, smaller, above dark grey, the forewing in the basal half metallic blue. Under surface lighter grey, on the forewing at the cell-end towards the costal margin with black shades, hindwing with black veins. Sierra de Guerrero.

P. 784, line 9 from below, after *sesara* insert:

brocela. **Th. brocela** Dyar I place here owing to its exterior resemblance. Above grey-brown, the costal margin of the forewing narrow light red, at the base broader; a black discal spot. Hindwings spread over with a bright blue with a small red anal-angular spot; on the lower median vein only one long, at the end white tail. Beneath light ashy-grey, both wings traversed by a brick-red median band which appears on the hindwing more in the shape of a spot and is distally bordered narrowly with white; before the distal margin a double whitish macular line; the spots on the tails small, red, the anal-angular spot with a black pupil. Captured in Peru (Cotahuasi) in October, at an altitude of 9000 ft.

P. 786, line 3 from above, after *lemuria* insert:

bennetti. **Th. bennetti** Dyar. Above bright metallic blue, on the forewing with a duller and darker discal spot; apex broad black, also on the hindwing. Under surface blackish-grey with an ochreous tint, on the forewing the straight postmedian is white, proximally bordered with black, the fine submarginal band is defined on the veins. The postmedian band of the hindwing is coloured like on the forewing, though irregular, extended outwards above and below the lower median vein. Spots of the tails small, red, with black pupils, proximally bordered with black. Peru, Pampaconas River, taken in August.

P. 788, line 12 from above, to *proba* add: (= *climicles* Dyar).

P. 788, „ 22 „ below, after *purissima* insert:

nippia. **Th. nippia** Dyar. Above blackish, on the forewing the basal third below the cell and the cell as far as the end light blue, hindwing up to the upper radial vein likewise blue. Under surface white, forewing with a faint white distal line, defined on the veins; on the hindwing the postdiscal band is thin, black, distally white with a flat W towards the anal margin; the small red spots on the tails are both pupilled in black; a feeble submarginal line. Expanse of wings: 25 mm. Mexico (Sierra de Guerrero).

P. 794, line 24 from below: add *devia* Mschr. as the synonym to the following species: *xeneta* Hew.

P. 795, „ 1 „ above: to *atrox* add *gentilla* Schs. as synonymous.

P. 797, „ 22 „ „ : for *tirrhaea* which becomes synonymous place: **pan** Drury.

P. 799, „ 23 „ „ : after *carla* insert:

minniles. **Th. minniles** Dyar. Above black, hindwing and proximal part of the forewing dull dark blue; without any tail. Beneath bright green, the proximal margin of the forewing grey. The postdiscal band of the hindwing broken up into lunar streaks, proximally black, distally white, between the lower radial and upper median vein and at the proximal margin receding considerably; a feeble cell-end streak; both the small spots on the tails red, towards the base black, the one at the anal angle besides white. Expanse of wings: 20 mm. Mexico (Guerrero).

P. 801, line 22 from above, *gentilla* Schs. is to be cancelled.

P. 802, „ 29 „ below, after *seudiga* insert:

viggia. **Th. viggia** Dyar. Forewing above black with a dark blue diffuse spot below the cell for $\frac{3}{4}$ of the length of the wing; hindwing almost quite blue. Beneath white-grey, forewing at the cell-end with a feeble dark ellipse, close behind it with a curved grey, proximally red-yellow band; an antemarginal blackish, proximally white line, somewhat angular on the middle radial vein; the discal area is of a purer white. Hindwing marked the same, the postdiscal band more intensely red, angled on the veins, a light grey submarginal lunar line, distally removed between the radial veins; at the border small roundish nebulous spots, the spot on the tail with a red ring. Expanse of wings: 19 mm. Mexico (Santa Rosa, Vera Cruz).

P. 802, line 4 from below, after *hyccara* insert:

heraldica. **Th. heraldica** Dyar. Above black, forewing towards the base somewhat blue, hindwing except the broad black costal margin and proximal margin quite blue. Beneath grey, towards the margin lighter, the postdiscal band white, proximally red-grey, on the hindwing defined on the lower radial vein with a flat W at the proximal margin. Both the spots of the tails red, the upper one with a black pupil. Expanse of wings: 20 mm. Panama (Porto Bello).

P. 804, line 10 from above, after *gamma* insert:

Th. ulia Dyar. Shape of the wings like in the preceding; above grey, spread over with a light blue, *ulia*, particularly in the proximal half of the hindwing; fringes and base of the costal margin light red-brown. Beneath ochreous-brown, the proximal part of the forewing lighter, both the wings with two broad, irregular, brown transverse bands through the cell, on the hindwing feebler; an antemarginal row of small, indistinct, dark spots, on the hindwing the space behind them is lighter. Peru (Cantas).

P. 806, line 21 from above, add to *canus* the synonym: (= *bunnirae* Dyar).

P. 806, „ 25 „ below, add to *sangala* the synonym: (= *callides* Dyar).

P. 806, „ 14 „ „ add to *amphrade* the synonym: (= *posetta* Dyar).

P. 807, „ 1 „ above, cancel *promissa* Mschlr. and place it as the synonym to *sabinus* Fldr.
p. 806, line 6 from below.

P. 807, line 9 from above, add to *serapio* the synonym: (= *mesca* Dyar).

P. 807, „ 16 „ „ add to *tella* the synonym: (= *castrena* Jones) and place the species on
p. 783, line 20 from above!

P. 808, line 20 from below, after *yojoa* insert:

Th. tyleri Dyar differs from *yojoa* (159 k) by its greyer, less reddish under surface, the postdiscal *tyleri*. lines being straighter, not broken or angular, without a red border; the spot of the tail small, without any red colour which is also absent at the anal angle. Peru (Coropuna), taken in October at an altitude of 14 500 ft.

P. 808, line 13 from below, to *thordesa* add the synonym: (= *zenaida* Dyar).

P. 809, „ 27 „ „ after *bubastus* insert:

Th. laceyi Barn. & McD. differs from *eurytulus* (145 h) by the orange anal angle of the hindwing *laceyi*, above and three more small, black antemarginal spots being white towards the base. There is a little tail. Under surface mouse-grey, the postdiscal spots orange instead of brown; in the basal area of the hindwing only one spot; the W distinctly prominent. Texas, described according to a ♀.

P. 810, line 1 from below, after *tarania* insert:

Th. otoheba Dyar is above black-brown, the anal angle of the hindwing spotted orange. Beneath *otoheba*. brown-grey with a somewhat oblique postdiscal band of the forewing as far as the lower median vein, and an irregular submarginal band. Hindwing with a broad carmine median band, which is defined on the lower radial and distally bordered by silvery-white arcs between the veins; the blackish subterminal line is dentate and distally red as far as up to the lower radial, forming a large red spot below it; between the spots of the tail a blue-dusted area. Expanse of wings: 21 mm. Dominica, in June and July.

P. 811, line 14 from below, after *eryx* insert:

Th. burica Dyar is above bright blue with a large black stigma and a broad black apex of the forewing. *burica*. Beneath bronze-grey, the cell of the forewing dark diaphanous, otherwise marked like *eryx*, but without any red at the spots of the tail, between which there is black and white dusting. Expanse of wings: 25 mm. Panama (Trinidad River).

Beside the species stated quite a number of American *Lycaenidae* have been described by old authors, such as FABRICIUS (*agrippa*, *anacreon*, *chiton*, *dindus*, *moncus*), GODART (*bazochii*, *cithonius*, *ergeus*, *gabelus*, *megarus*, *nebis*, *sinnis*, *strophius*) and others, which it has hitherto been impossible to throw light upon; probably the greater part will represent synonyms with other species; for this reason we have left out these mostly insufficient descriptions.

B. Grypocera, broad-headed day-butterflies.

As has already been stated in Vol. I, p. 329, this second Division (HAASE denominates it *Netrocera*) is not equivalent to the first to which all the families of day-butterflies belong except the Hesperidae *), inasmuch as it comprises only a single group of relatively homogeneous butterflies, whereas the *Rhopalocera* comprehend very heterogeneous formations, such as *Morpho*, *Chrysophanus*, *Leucidia*, *Leptocircus* etc. The differences of the two divisions have already been briefly stated at some other places **) and are here once more classified in the following characterization of the *Hesperidae*, to which we may, therefore, refer.

1. Family: Hesperidae, Skippers.

The *Hesperidae* are mainly distinguished from the other day-butterflies by the forehead being very broad, for which reason the eyes are farther remote from each other than in any *Rhopaloceron*. This conspicuous mark, together with the robust structure of the body and a great uniformity in the shape and venation of the wings served LATREILLE as the foundation for his thoroughgoing separation of this family from the stock of the other day-butterflies. LATREILLE's grouping is also aided by special morphological examinations; as for instance REUTER's palpal spot exhibits great conformity with all the *Hesperidae*, but differs entirely from that of all the other day-butterflies ***). Moreover, the venation strikingly deviates from that of the *Rhopalocera*, so that all the systematizing authors, although they did not give expression to it in the scheme of their systems, still laid great stress upon the caesura between the *Hesperidae* and the other day-butterflies, e. g. HERRICH-SCHÄFFER, SCUDDER, TRIMEN a. o.

The number of Hesperid forms enumerated by MABILLE *), about 2150, has since that time increased by several hundreds, although numerous species having often expressly been quoted as doubtful by the said excellent expert of this family turned out to be synonymous or not maintainable for some other reason. The general geographical range has been dealt with already in Vol. I, p. 329; we may once more state here that America is extraordinarily favoured in the distribution of the *Hesperidae*. In spite of the great flying power of the butterflies, they are still absent in a comparatively great number of islands, and consequently seem to be entirely unfit for flying across the ocean. But where compact tracts of land allowed them to rest temporarily from their flight, which seems to be a necessity to them, they were able to spread across enormous districts. Thus *Calpodus ethlius* is distributed over more than 70 degrees of latitude, some *Hesperia* (e. g. *alveus*) over 150 degrees of longitude. As the Hesperids are besides very fond of flying much and far and to a certain degree even of wandering, it is natural that they vary little in the countries connected by strips of land even at great distances; but as they never fly very unintermittingly, there had to be formed particular local forms in all the places separated by the sea. In the far remote New Zealand the *Hesperidae*, being yet well represented in Australia, are entirely absent, and even in the Canary Islands, which are not difficult to reach for palearctics, there is but 1 species, *Adopaea actaeon*, however in the form *christi* regarded by many as a separate species.

We have already pointed out (Vol. I, p. 329) that the *Hesperidae* are extremely heliophile. This explains their immense preponderance in the Tropics, which decreases rapidly as soon as we come to the temperate zones, while on proceeding farther towards the polar regions the state of things is reversed. Only one single Hesperid can be regarded as an arctic butterfly, *Hesperia centaureae*, and since in the north there is a less interrupted connection of countries between the New and Old World, this species is also the only one which America has in common with any of the other faunas of the world, i. e. with the palearctic fauna. All the other, almost 2000 Americans are separate species, although some North Americans can yet be recognized to be representatives of certain palearctics.

The eggs of the *Hesperidae* vary greatly in their size, but in their exterior shape they are rather exactly conformable. They are hemispherical, above more or less flattened, ribbed radiately, and often distinctly reticulated. The ♀♀ deposit them always singly and, as far as is known to me, also always in moderate numbers on the food-plant or its surroundings. The food-plant itself may belong to nearly all the families of plants; very many species live on the most highly developed plants, such as Papilionaceae, Caesalpinaeae and Mimosae, whilst on

*) Some writers spell the name „Hesperiidae“ so as to distinguish it from the mythological name of the daughters of Atlas. But since both words are equally derived from the name „Hesperia“, they may as well be homonymous.

**) Vol. I, p. 329.

***) Certain resemblances in the exterior of the palpi between the *Hesperidae* and some genera of other groups of day-butterflies (*Eurybia*, *Allotinus* etc.) prove to be merely externally morphological.

*) WYTSMAN. Genera Insectorum, Fasc. 17 (1904).

the other hand even Monocotyledons are visited by them, such as grass, cereals, Liliaceae, bananas, and even palm-trees which are otherwise scarcely uneatable for larvae. Between some plants and the Hesperids visiting them there even seems to prevail sometimes a mutual relation in such a way that the butterflies have also become the fructifiers of those blossoms of plants, the leaves of which are eaten up by their larvae; at least this would make it comprehensible that for instance *Calpododes ethlius* is provided with an enormously long siphon so as to enable it to visit the deep calyces of the Canna-blossoms, which are otherwise accessible to very few butterflies, and the leaves of which serve their larvae as food. I presume that by similar symbiotic relations the sphinx-like long siphons of other Hesperid genera (*Perichares*, *Gangara* etc.) can be explained.

The larvae are mostly almost bare, i. e. very sparsely covered with downy hairs standing singly, or with very short plush-like hair; their colour is frequently green, but often also snow-white or bone-coloured, in the larger species frequently speckled or striped like a zebra. The head usually sits on a very much strangulated neck; it is mostly downwards broader, tapering off towards the vertex, where it is, however, also sometimes notched and thereby of a cordiform shape. Very peculiar is a bristly hairing of the face as it often occurs in the *Pyrrophyginae*; in other species the frontal vesicles show dark, eye-shaped dots which, together with a nose-like middle-streak and transverse mouth-marking are apt to recall a human face or that of a monkey. The larvae rarely live in the open, but in feeding they sometimes creep out from the leaf in which they are encased; some also only put out their head in feeding. The case itself consists of a leaf being rolled up at the margins but it may also represent a more or less highly artistic funnel which very often discloses the larva's abode to the collector. The larva, in the tropical forms, grows up rather quickly, but it usually feeds only at night even in the most day-loving species. For the pupation most of them do not construct a real cocoon, but the transformation takes place rather incompletely protected in a carelessly guarded niche of a leaf, out of which one sees the pupa looking out being often very brightly coloured, frequently snow-white or hoary bluish.

The pupae entirely have the shape of the body of the imago, so that the broad head and the far separated eyes can already be recognized. The head frequently exhibits a cone directed forward sometimes prolonged in the shape of a thorn; between the costal margins of the wing-cases, the case for the siphon runs along, which is often so long that it projects beyond the anal end of the pupa like a spike. The pupa likewise sometimes has a marking like a face, i. e. blackish dots on the eyes, sometimes with a dark middle streak. The pupal stage usually lasts for a short time in the tropics, often only a week or little more. The wings very quickly grow stiff after creeping out, so that the imago is able to fly already a few minutes after leaving the pupa.

As we have already mentioned in Vol. I, p. 329, the main flying time is concentrated upon the hottest months of the year in the temperate districts; only few fly in spring, and these often appear yet in a second generation in midsummer. In the Northern States most of the Hesperids fly only in one generation from June to August. In the Southern States they are often followed by another generation in autumn, and in Tropical America very many Hesperids in almost the same frequency fly all the year round without any pause; thus, during a longer spell of dry weather in which the other day-butterflies sometimes disappear nearly altogether, they form the only remaining moment enlivening nature. Almost without exception they eagerly visit flowers some of which have such a great attractive power upon the Hesperids, that they are continually surrounded by whole swarms of them. They very rarely come to the bait; I never met with them on the sap dripping from trees, but they often drink water from pools and banks of rivers. They eat dry materials serving them as food by pouring out drops of liquid from the anus on to the base from which they suck then, as KÜHN proved for Indian and K. DIETZE for European HESPERIDAE. DIETZE observed that an *Augiades sylvanus* dropped more than 200 of such clear small drops on the base to be sucked up (at intervals of about 5 seconds), which it then wholly absorbed again by means of the siphon being bent below the body. Their flight is somewhat skipping, in floating darts, for which reason they are called „skippers“ in English. It is a buzzing and mostly impetuously swift flight, so that most of the species are thus scarcely recognizable, let alone to be overtaken. Nevertheless it is easy to capture them, since they are not timid, and not only allow themselves to be approached when drinking from the flowers, but also mostly remain sitting without the least fear when they are on the look-out on the top of a bush or on a twig projecting into the open space.

The Hesperids have two modes of keeping their wings. One part of the species keeps the wings always spread out flatly, often in such a way that the apical part of the forewing appears as if bent down over the horizontal line; in these species the distal margin is frequently angular, lobate, gnawed out, dentate or laciniiform. The genera, taking up this position, mostly consist of velvety black or deep dark brown species (*Eantis*, *Achlyodes*, *Antigonus*, *Sebaldia* etc.); they are nearly all confined to the tropics, where they represent the more northern *Thanaos* and *Thorybes*. The second group, containing more species, folds the wings together while being at rest, like the day-butterflies do, whereas in the swarming time, while it settles down only temporarily, it keeps the wings in such a way that the forewings are turned upward parallel to each other, though not

folded together, whilst the hindwings are being kept somewhat more flatly, sometimes even almost appressed to the base; hereto belong the greater part of the *Pamphilini*. In drinking from the blossoms, these species frequently keep their wings quite closed (*Carystus*) or also, like the *Lycaena*, half-opened (*Hesperia*).

The position of the wings often influences the colouring, which may be very variable in the *Hesperidae*. If, as for instance in *Carystus*, always only the under surface of the wings is exhibited, it is variegated, on a yellow or azure ground there run stripes or bands of intense colours; if the under surface is kept concealed, as for instance in *Pythonides*, *Milanion*, *Systasea* etc., the under surface is generally pale with a blurred marking. Very common are small or large vitreous spots and dots like the pricks of a needle, often arranged in chains, and very characteristic for the different species by their arrangement. Metallic colours, particularly golden green or a brilliant blue, are exhibited by whole genera and comprise both wings and body; there may even occur the strange picture that quite unicolorously black butterflies have metallic green or golden heads.

Among the colours deep red is represented the least (*Haemactis sanguinalis*), whilst an ochreous golden yellow occurs most frequently. Still oftener, however, the upper surface of the wings is of a deep black-brown, only interrupted by small vitreous spots and sometimes with a very bright colour in the anal area. There are no leaf-green *Hesperidae* known, nor any with a colour like the bark of trees as is exhibited on the under surface of the wings by so many species of day-butterflies, such as *Caligo*, *Vanessa*, *Polygonia* etc.

Nor do the Hesperids imitate leaves, as it occurs so often in America (*Anaea*, *Catopsilia*, *Historis*). There are certainly sleeping specimens sometimes found dreaming on a blossom, but the variegated species still seem mostly to creep into their hiding-place for their repose. The robust body, the narrow wings, of which the hindwings are often very closely folded together, facilitate their creeping under the cover of the vegetation, so that a protective colouring has not been developed. The great resemblance of the members of one genus among each other (compare e. g. t. 162) makes us presume that exterior influences have been of very little formative value and that the different species have only differentiated themselves from one another to such an extent as was necessary for the distinction. The number of enemies seems to be very small for the imagines; I saw birds from the family of the *Ixus* snatching at them and chasing the numerous swarming Hesperids away from the bushes, but these birds did not chase them systematically, as for instance a flycatcher or fire-tail chase the flies, but the noisy and furious pursuit of the *Ixus* seemed to be more of an amusement and to arise more from the playful bent characteristic in the *Ixus jocosus*. On the whole, the *Hesperidae* remained entirely unmolested by the birds; I even was able to observe humming-birds shunning in their visit to flowers those blossoms that were occupied by larger Hesperids such as *Eudamus*, *Thymele*, *Goniuris*.

The *Hesperidae* seem neither to be particularly attacked by parasites. I once had more than 50 bags filled with pupae of *Calpodus ethlius*, which I had gathered in the agricultural park of Palermo near Buenos Ayres; not one specimen supplied a parasite. Also the numerous pupae of *Pythonides cerealis* which I discovered in the course of a year in Brazil, all yielded sound imagines. If the latter species were very much pursued, it would be incomprehensible that their pupae exhibit a bright, snow-white colour and hides so incompletely in the green leaf being scarcely drawn together, that it can immediately be noticed even at greater distances.

The Hesperids have neither developed any colours and markings which would have to be regarded as the effects of mimicry. Except some very rare resemblances occurring now and again in otherwise non-mimetic genera, all the Hesperids exhibit an exterior found in no other group of butterflies remarkably repeated; and the sporadic cases of (mostly also only very slight) resemblance are so rare that they may very well be explained as casual, particularly since such casual resemblances exist also in such cases where mimicry is out of the question owing to the incongruence of the patriae, as for instance between *Rhopalocampta aescylus* *) from West Africa and American *Pyrrhopyge*! **). In a somewhat greater number of cases we find resemblances of *Hesperidae* with members of the family belonging, however, to another genus. Thus certain *Aethilla* and *Pyrrhopygopsis* resemble the *Pyrrhopyge* to such an extent that one of these genera was denominated after it. In a similar way we find in some *Phocides* the otherwise very sporadic scheme of colouring of certain *Jemadia*. But although it is a nonsense to explain a resemblance, as for instance of *Limenitis archippus* to *Danaidu archippus*, by the „homogeneous effect of homogeneous exterior influences“, we still can easily imagine a certain equally working effect of the same exterior forces in the close affinity of similar species. However, the biological conditions of the *Hesperidae*, particularly of the neotropical species concerned here are still too little known to give a definite answer to the question whether there occurs any mimicry in the *Hesperidae*.

As the most destructive enemies to the Hesperid imagines, beside amphibia and reptiles, the Arthropoda are to be looked upon. Above all the spiders. Although the Hesperids, owing to their powerful wings, often free themselves from the nets of weak spiders, I often found in Brazil whole galleries of horizontal, somewhat purse-

*) Comp. Vol. XIII, t. 72.

**) Comp. Vol. V, t. 162.

shaped cobwebs with tough, almost sticky threads in which there hung not only large *Hesperidae*, but also large and powerful *Papilio* (*polydamas*) and even beetles of the size and strength of large Scarabaeids. I furthermore observed Mantids that had picked out their post at the ends of twigs in so insidious a way that the Hesperids flew directly into their arms.

The division of the Hesperids causes rather great difficulties by reason of the great conformity of the species and genera among each other. For a long time nobody wanted to try a scientifically well-founded classification, until WATSON, in 1893, solved this task in a very satisfactory way by the abundant material of the British Museum. He based his task upon the preliminary studies by SCUDDER and created a system of the *Hesperidae*, which was later on yet improved by P. MABILLE by furnishing a catalogue of the whole family which, though it seems to be not quite complete and somewhat superficial in the citations, can still scarcely be excelled in its zoogeographical argumentation, and which is therefore retained here without any essential alteration.

The *Hesperidae*, in their total appearance, are mostly small butterflies, not exceeding an expanse of few centimeters.

The head being conspicuously broad, as we have already mentioned, is not vertically, as in the *Rhopalocera*, but more horizontally placed, as in the Sphingids; so that the frons shows upwards instead of forwards. The palpi have a stout basal and middle joint, they are mostly also very much inflated, the terminal joint being small, styloid. Also the antennae distinguish the *Hesperidae* from all the other day-butterflies by the club being not only bent round like a hook, but also comprising far more antennal joints than in any other family of day-butterflies. Particularly the apex of the spindle often bends off in a sharp flange rectangularly from the shaft.

The thorax is uncommonly robust and its chitinous cuirass offers great resistance to the pressure of the fingers; it is, however, not elastic and tenacious, as for instance in a Danaid or Zygaenid, but delicate, and the animals having once been pressed are no more able to recover their flying power; legs and antennae are easily broken, but particularly only a rude touch at the head suffices to make the palpi drop.

The abdomen, though it sits broadly on the thorax, is nevertheless slender, pointed, not heavy nor strongly inflated. It is usually just as stout in the ♂ as in the ♀, so that it is often not easy at first sight to distinguish the two sexes. It is never seen conspicuously lengthened.

All the 6 legs are adapted for resting. They also exhibit a peculiarity by the hindlegs, mostly having 2 pair of well-developed spines, as we find them also in *Heterocera*.

The venation likewise greatly deviates from that of the other day-butterflies. The cell of the forewing is usually very long and narrow, sometimes open like that of the hindwing. The subcostal veins branch off at almost the same distances, so do the radial veins from the discocellular, wherever it is present. Thereby the phase is shown that all the subcostal veins of the forewing touch the costal margin, which imparts to the scheme of venation a peculiar primitive appearance.

Subfamily: **Pyrrhopyginae** Wts.

By the peculiar shape of the antennae, this well-characterized subfamily, which is confined to the New World in its distribution, is always distinctly to be separated from all the other *Hesperidae*. They are almost without exception large, strong species, on the bodies and wings of which dark colours, often with a deep blue or green lustre, are predominant, sometimes with hyaline spots. Most peculiarly almost all the forms find imitators among the other subordinate groups.

The club of the antenna is strong, quite cylindrical or also slightly conic, rarely very little pointed, but never with the long, turned down point which we find otherwise. The club is usually more or less strongly bent at the beginning of the thickening. The cell of the forewing is long, at least $\frac{2}{3}$ of the length of the costal margin, mostly longer. Vein 5 of the hindwing is often absent. The ♂ has never an overturned costal fold. While being at rest, the wings are usually spread out horizontally.

1. Genus: **Pyrrhopyge** Hbn.

This genus comprises very numerous, partly extremely similar species which are difficult to separate and perhaps neither are separable as distinct species. Nearly all are large, strong animals with black body and wings, often with a bronze-green or deep blue lustre, often spotted red on the head and abdomen. On the broad, mostly pointed forewings the discoidal runs very obliquely, the upper median vein rising somewhat behind the middle of the cell. On the hindwing the lower radial and upper median vein rise unpetioled, the middle radial being absent. The hind tibiae are strongly haired outside.

The *Pyrrhopyge*, according to statements by Dr. SEITZ, are conspicuous animals owing to their almost invariably one-coloured black colouring and the mostly glaring-red ends of their bodies. When they fly past swiftly, these red places are difficult to notice for the human eye, but the resting insect makes the impression

as if its body were bleeding in front and behind. As the flight is impetuously swift, the animal escaping its enemies scarcely needs any protection, whereas on the topmost branches of bushes of 1 or 2 m height, which are chosen by the ♂♂ as their point of observation, one of the most dangerous enemies of the tropical butterflies is lying in ambush, the praying-cricket which even catches butterflies of the size of strong *Papilio* with a sure dart and is able to devour several large specimens a day. In the waiting attitude taken up by the *Pyrrhopyge* on the tip of the twig, the forewings are half erected, the hindwings somewhat more lowered; a position sometimes met with in European *Adoptra* or *Pamphila*, whereas other *Pyrrhopyginae*, such as the blue-striped *Jemadia*, the *Mimoniades*, *Myseclus* etc. keep their wings spread out when at rest, about like *Thanaos tages*. The larvae of *Pyrrhopyge*, as far as we know, are thinly haired on the body, shaggily on the head, brown or reddish with yellow, zebra-like stripes. They live on different trees, so on Gujava pear-trees (*Psidium pyrifera* and *pomiferum*), in leaf-cases. The pupae are haired, too. The imagines fly along the roads and skirts of woods in a raving, somewhat skipping flight and are fond of drinking from wet places on the roads. The *Jemadia* and *Mimoniades* love the umbels of blossoming bushes, where they are met with in the company of similarly coloured Hesperids from other groups, such as *Phocides* and *Pyrrhopygopsis*.

P. hyperici *Hbn.* (162 a) is easily recognized by the rounded white spot on the upper surface of the *hyperici*. hindwing and the oval white spot on the hindwing beneath at the base. Brazil.

P. sergius *Hpffr.* (= *leucoloma Ersch.*) (162 a) is above quite black with white fringes, red head, *sergius*. collar and anus; beneath the hindwing exhibits a blue-white, broad marginal band extending from near the proximal angle almost to the costal angle and being somewhat traversed by the dark veins. From Colombia, Peru and Brazil.

P. araethyrea *Hew.* (= *araethyrea Mab.*) (162 a) is somewhat larger, otherwise the same, but the *araethyrea*. blue-white marginal band of the hindwing is present also on the upper surface and is traversed above by 6, below by 7 black veins. Ecuador.

P. aziza *Hew.* differs from *araethyrea* by the marginal band being narrower above and crossed only *aziza*. by the rays of five black veins. New Granada.

P. garata *Hew.* (162 a). Here the blue-white marginal spot only extends to the upper median vein, *garata*. but instead it extends proximally to the discocellular and is traversed only by 3 black rays. The red head is posteriorly bordered with black. Surinam.

P. scylla *Mén.* (162 a) has above and below black wings with white fringes which are smoky on *scylla*. the forewing from the middle radial vein towards the apex. Head and palpi are black, shoulders, shoulder-covers and anus red, and the anterior femora are spotted red, too. Peru and Bolivia.

P. decipiens *Mab.* is the same, only of a deeper black, and on the costal margin of the hindwing *decipiens*. beneath it exhibits a red spot between the costal and subcostal. Ecuador.

P. melanomerus *Mab. & Boull.* differs from *scylla* (162 c) by the anterior femora being quite black *melanomerus*. and by the fringes of the forewing being smoky only at the extreme apex. Described from Bolivia.

P. papius *Hpffr.* is recognizable by the red palpi being bordered with black. The fringes of the forewings *papius*. are brownish from the lower radial vein to the apex. South America.

P. creona *Dre.* (= *aurora Mab.*) (162 a). Like *scylla*, but of a browner ground-colour, beneath *creona*. dusted red, the shoulder-covers prolonged to long hair-pencils. Bolivia.

P. charybdis *Dbl.* (162 b) is bluish-black with carmine head and anus, on the vertex there is a thick *charybdis*. black dot, behind it a black transverse streak. The fringes are of a pure white as far as the apex. South America.

P. zenodorus *G. & S.* (= *thasus Btlr.*) is alike, but the head and anus of a lighter red, without *zenodorus*. the black dot on the vertex, the fringes of the forewing are smoky from the upper radial vein to the apex. Mexico.

P. polemon *Hpffr.* (162 b) has, like in *zenodorus*, towards the apex brownish fringes of the forewings, *polemon*. and the dot on the vertex is absent, but it has the deep carmine of *charybdis*. Brazil.

P. menecrates *Mab.* (162 b) differs from the preceding immediately by the red base of the shoulder- *menecrates*. covers. Distributed from Brazil to Bolivia.

P. zeleucus *F.* (162 b) is much larger than *charybdis* and has red-spotted anterior femora. Brazil. *zeleucus*.

P. lampros *Hpffr.* (162 b) is separated from *zeleucus* by black anterior femora and the fringes being *lampros*. somewhat brownish at the ends of the veins, particularly at the apex of the forewing and proximal angle of the hindwing, so that the latter look somewhat undulate. Brazil.

- rhacia*. **P. rhacia** Hew. (162 b) is at once discernible from all the species by the white palpi and the white-striped anterior femora, as well as the red thorax. Minas Geraes.
- proculus*. **P. proculus** Hpffr. (= *zeleucus* Erichs., nec F.) (162 b) differs from the preceding by only the anterior head being red, the posterior head being black as far as the eyes. Guiana.
- roscius*. **P. roscius** Hpffr. exhibits a red belt across the middle abdominal rings, but the head is quite black, only the shoulders being spotted red and the anus red. From Brazil.
- dulcinea*. **P. dulcinea** Plötz (162 c) has 3 white transverse lines on the head: on the forehead, between the antennae and on the hindhead; palpi, base of shoulder-covers and apex of abdomen are red, the shoulder-covers finely bordered with red or orange-yellow. Mexico to South America.
- semidentata*. **P. semidentata** Mab. This species has, like the 6 following ones, a white base of the hindwing beneath, also the base of the forewing is white; the fringes of the hindwing are speckled black on the ends of the veins, on the forewing white as far as the upper median vein, from there to the apex black. Colombia.
- intersecta*. **P. intersecta** H.-Schäff. (162 c) differs by the fringes of the hindwing being only speckled in the proximal half, those of the forewing being almost entirely white. The red head is spotted black, the thorax quite black. South America.
- denticulata*. **P. denticulata** H.-Schäff. deviates from the preceding by the fringes being yellowish at the base. Head, prothorax and apex of abdomen are red. South America.
- fluminis*. **P. fluminis** Btlr. (162 c) has unspeckled fringes like the 4 following species. On the brownish under surface of the forewing only the costal-marginal base is white, the fringes blackened only at the extreme apex. Amazon.
- bixae*. **P. bixae** Cr. (= *maenas* F., *tiribazus* Plötz) has the whole base of the forewing beneath blue-white, the fringes of the forewing are smoky from the upper median vein. Guiana.
- latifasciata*. **P. latifasciata** Btlr. (162 d) is recognizable by the extraordinarily broad white basal spot of the hindwing, whereas the base of the forewing remains quite black; fringes like in *bixae*. Colombia and Peru.
- phidias*. **P. phidias** L. (162 c, d) differs from *latifasciata* by its smaller white basal spot, the fringes being only brownish from the lower radial vein towards the apex. From Guiana and South America.
- infantilis*. **P. infantilis** Drc. (162 c) is smaller than the preceding, the white spot on the hindwing beneath is placed somewhat more into the middle of the wing, indistinct and strewn with a dark tinge. Peru.
- agenoria*. **P. agenoria** Hew. (162 d) has, like the 6 following species, a red-spotted proximal angle of the hindwing, and is recognizable by its black head and abdomen (only the collar being red) and by the under surface of the hindwing being all black. Known from Pará.
- cruor*. **P. cruor** Drc. (166 a) entirely resembles *agenoria*, but in the middle of the forewing it shows a broad transverse band of modified, differently placed scales, which stands out against the ground of the forewing indistinctly darker. Described from Pozuzo (Peru).
- sanies*. **P. sanies** Drc. (164 d) entirely resembles *cruor*, but the band of the forewing is here white, semi-diaphanous and somewhat opalescent, it also runs more obliquely. From La Paz (Bolivia).
- styx*. **P. styx** Mschlr. (= *anina* Plötz) (166 a) has beneath a white-spotted base of the hindwing; head and prothorax are red, the red spot of the hindwing is very large and occasionally extends beyond the lower median vein. Colombia.
- passova*. **P. passova** Hew. (162 d) differs by an entirely black prothorax and the spot of the hindwing being bordered with black; the basal spot of the hindwing beneath is decidedly bluish. Amazon, Bolivia.
- gortyna*. **P. gortyna** Hew. (166 a) is at once recognizable by the hindwing being spotted green-white above in the middle. From Ega.
- galgala*. **P. galgala** Hew. (= *strigifera* Fldr.) (162 d) cannot be confounded with any other species for the yellow oblique line exhibited by the forewing above, by the hindwing also beneath. The body is black except the red hindhead and apex of the abdomen. Colombia. Brazil.
- gellias*. **P. gellias** G. & S. (162 d) exhibits along the distal margin of the hindwing high, triangular, silvery blue spots. Costa Rica.
- gazera*. **P. gazera** Hew. (162 d) differs from *gellias* by the broader and rounder shape of its wings, the distal-marginal spots are less high and extend only to the upper radial vein. South America.

P. jonas *Fldr.* (= *cydonia Drc.*) (162 e) is a large, beautiful species with undulate white fringes; *jonas*. palpi and abdominal apex are yellow. From Mexico.

P. josepha *Plötz* is very similar, but it has yellow fringes and pale red palpi. Brazil. *josepha*.

P. josephina *spec. nov.* (162 g) has the same shape as the two preceding ones, the fringes are white, *josephina*. with a yellowish tint, with a fine antemarginal orange-yellow line being on the forewing only as fine as a hair. Head, palpi and apex of abdomen are red, the femora black. Described according to 1 ♂ from the Songo, Bolivia (FASSL).

P. araxes *Hew.* (= *cyrellus Plötz*) (162 e) is above brown with several small hyaline spots, beneath *araxes*. the hindwings are deep ochreous-yellow with two dark brown macular bands, between at the costal margin another small spot and a broad brown margin which is proximally sharply defined by black lunae. Mexico to Colombia.

P. arizonae *G. & S.* (= *araxes Holl.*) is very much alike and may be the northern representative *arizonae*. of the preceding species, exhibiting on the hindwings beneath less distinct, more blurred transverse bands, and the marginal area being here blackish is not sharply defined. Arizona.

P. maculosa *Hew.* (= *agathon Fldr.*) (162 e) resembles the preceding, the ground-colour is blacker *maculosa*. and the small spots are smaller and whiter. The larger basal half of the hindwing beneath forms a broad, orange-ochreous area. Brazil.

P. erythrosticta *G. & S.* (162 e) differs from *maculosa* by a red spot below the base of the cell of *erythro-* the forewing. Distributed from Central America to Colombia. *sticta*.

P. cossea *Drc.* exhibits above on the forewing the same spotting as *maculosa*, the hindwing shows *cossea*. an orange-red band extending from the distal margin to the proximal margin. Beneath the base of the forewing is more extensively spotted orange, and at the costal margin there is a red dot. South America.

P. thericles *Mab.* is above quite black, also the fringes of all 4 wings black, only the head and apex *thericles*. of abdomen red; on the hindwing beneath a moderately large, white, oval spot. Bolivia.

P. cardus *Mab.* differs from *thericles* by a much larger white spot on the hindwing beneath, to which *cardus*. a minute blue spot corresponds above. Bolivia.

P. hylaeus *Mab.* is larger than *cardus*, the spot of the hindwing beneath decidedly blue-white, divided *hylaeus*. into 8 rays by the veins with a rounded end. Bolivia.

P. creon *Drc.* (= *cyclops Stgr.*) (162 e) is a large species of a metallic blue lustre, with a round red *creon*. spot near the proximal angle of the hindwing. Distributed from Honduras to Colombia.

P. aerata *G. & S.* (166 a) is bronze-green and exhibits at the cell-end of the darker hindwing 3 minute *aerata*. red spots. On the abdomen there are 6 yellow lateral spots. Bolivia.

P. hygieia *Fldr.* (= *bogotana Reak.*) (162 f) is likewise of a bright metallic blue lustre and has, like *hygieia*. the following species orange-red fringes of the hindwing, whereas the fringes of the forewing remain black as well as the head and apex of abdomen. The anterior femora are spotted red; the species is particularly characterized by the broad orange-red marginal band being situate before the fringes of the hindwing. Ecuador.

P. rufinucha *G. & S.* (162 f) differs from *hygieia* by the orange-red marginal band of the hindwing *rufinucha*. being much narrower, and by its red neck and palpal base. Bolivia.

P. aesculapius *Stgr.* (= *variegaticeps G. & S.*) (162 f). has black anterior femora and no orange *aesculapius*. marginal band in front of the red fringes of the hindwing. Central America.

P. insana *Stgr.* differs from the preceding by a narrow red marginal band before the fringes of the *insana*. hindwing, extending as far as the subcostal vein, and by its red neck. Described from the Chiriqui.

P. fassli *Boull.* approaches *hygieia* (162 f), but it deviates above by the brilliant blue lustre of *fassli*. the wings exhibiting a slight greenish reflection. Forewing with a moderate black marginal band; the hindwing shows a rather broad, red band extending beyond vein 6 almost to vein 7. Fringes of the forewing intermixed with red-orange. From *insana Stgr.* it deviates by the collar being black, not red, from *aesculapius Stgr.* by the red band not extending to the costal angle. Colombia, Peru, Bolivia.

P. kelita *Hew.* (162 h) is very easily recognizable by the 3 or 4 orange-red, in the ♀ more yellow *kelita*. longitudinal rays of the hindwing; of the same colour are the fringes, somewhat smoky at the extreme apex of the forewing. Head, palpi, borders of the shoulder-covers and apex of abdomen are red, the anterior femora spotted red. — The form *tristis Mab. & Boull.* has the fringes of the forewings smoky already from the upper *tristis*. median vein. The species is found in Bolivia, Peru and Ecuador.

- phaeax*. **P. phaeax** *Hpffr.* (162 g) is above black, sometimes with a slight brown tint, both wings with red fringes. Head and palpi are black, the collar laterally, as well as the borders of the shoulder-covers and apex of abdomen red, the anterior femora spotted red. On the base of the hindwing beneath, like in the 5 following species, a red spot. Peru.
- croceimargo*. **P. croceimargo** *Mab. & Boull.* (162 f) looks very much like *phaeax*, but it has quite black anterior femora and conspicuously lustrously black-striped veins on a more olive-brownish ground. Besides, the fringes are more yellow, not so red. Bolivia.
- martena*. **P. martena** *Hew.* (166 b) is distinguished by the very broad, orange-red marginal band of the hindwing, which is about 3 times as broad as the fringes. The base of the hindwing beneath exhibits a red spot which is radiately prolonged to the border below the costal vein. Ecuador.
- telassa*. **P. telassa** *Hew.* (162 g) is like the preceding, but the marginal band of the hindwing is less broad, and on the under surface the red basal spot of the hindwing is not prolonged to the border. Ecuador. —
- telassina*. f. **telassina** *Mab. & Boull.* from Pará has the fringes more or less dusted black, and the marginal band of the hindwing is obsolete.
- cleopas*. **P. cleopas** *Mab. & Boull.* has no marginal band before the broadly orange fringes of the hindwing; the veins are prominently lustrous black as in *croceimargo*. The apex of the abdomen and the interior margin of the shoulder-covers are red. Bolivia, Peru.
- mendax*. **P. mendax** *Mab. & Boull.* has much narrower fringes which are smoky towards the apex on the hindwing; the wings are of a purer black, the black shoulder-covers only at the end with some red hairs. Peru.
- pelota*. **P. pelota** *Plötz* (166 a). In the following species the red spot of the base of the hindwing beneath is absent. *pelota* is a species with a metallic green lustre and light yellow fringes, in front of which there is on the hindwing a light yellow narrow marginal line. Head, shoulders, and apex of abdomen are red, the anterior femora spotted red. — Larva of a bright red-brown, with yellow transverse belts; on *Psidium*. Brazil and Paraguay as far as Argentina.
- fimbriata*. **P. fimbriata** *Plötz* differs by deeper orange fringes, absent marginal line of the hindwing and black abdominal apex. Described from Mexico.
- rubricor*. **P. rubricor** *Mab. & Boull.* from Ecuador has deeper orange-red fringes which are blackened on the forewing from the middle radial vein to the apex, as well as by more extensively red shoulders and interior margins of the shoulder-covers.
- zereda*. **P. zereda** *Hew.* (= *rufipectus* *G. & S.*) (162 f) is a large, green and blue species, with a broad, proximally dentate, orange marginal band of the hindwing, the femora and legs spotted and striped orange. Head, palpi and abdominal apex quite black. Ecuador.
- chalybea*. **P. chalybea** *Scudd.* (= *zereda* *Hew.* part.) (126 g) differs from *zereda* by its black femora. From Mexico and Central America as far as Venezuela.
- amyclas*. **P. amyclas** *Cr.* (= *amiatus* *F.*, *laonome* *Swms.*) (162 f) has on the hindwing and on the forewing an orange-yellow marginal band before the fringes. Head, shoulders and apex of abdomen are red, the shoulder-covers black. Guiana.
- hadassa*. **P. hadassa** *Hew.* (162 f) has orange-red fringes and on the hindwing a dentate marginal band before them, which is broader than the fringes. The fringes of the forewing are mostly blackened towards the apex; the proximal half of the shoulder-covers is red. Ecuador and Bolivia.
- pseudohadassa*. **P. pseudohadassa** *Mab. & Boull.* has the marginal band of the hindwing not broader than the fringes which are on the forewings blackened to a small extent. The proximal border of the shoulder-covers is more narrowly red. From Peru.
- tenuis*. **P. tenuis** *Mab. & Boull.* Here the marginal band of the hindwing is still narrower than the fringes, more orange-yellow. Head and palpi are black, the proximal margin of the shoulder-covers narrowly red like in the preceding. Peru.
- hades*. **P. hades** *Mab.* (162 g) has quite black shoulder-covers, only laterally on the shoulders somewhat red; the head is likewise red with a large black dot on the frons and a black streak between the eyes; otherwise like the preceding. Bolivia.
- phylleia*. **P. phylleia** *Hew.* (162 g) differs from *hades* by deeper red fringes, the black frontal dot is much smaller, the streak between the eyes is absent. From Bolivia.
- haemon*. **P. haemon** *G. & S.* is like *phylleia* (162 g), but the narrow orange-red margin of the hindwing is here broad; from *hadassa* (162 f) it differs by the red head. Forehips black. Costa Rica, described according to a ♀ in the Coll. STAUDINGER.

J. fleximargo *Mab. & Boull.* is distinguished by its entirely black hindhead; the marginal band of the hindwing is broader between the median and radial veins than the fringes are, on both sides of them, however, narrower; the fringes of the forewing are blackened towards the apex. Bolivia.

2. Genus: **Amenis** *Wts.*

The genus contains animals greatly resembling the preceding in their exterior, chiefly distinguished by the bare posterior tibiae, the wings being generally narrower and the apex of the forewing somewhat prolonged.

A. pionia *Hew.* (162 h) is black with a deep blue metallic reflection, at the anal angle of the hindwing silvery blue, prominent spots; in the middle of the forewing there are two red spots below each other. On the under surface particularly the hindwings are blue-white towards the base, the fringes of all the 4 wings are of a pure white; the distal margin of the hindwing is concave in the ♂, the anal angle extended in the shape of a lobe. Colombia.

A. ponina *H.-Schöff.* is extremely similar, but it has dirty yellow, instead of white fringes, and those of the hindwings are much longer. Panama.

A. affinis *H.-Schöff.* (162 h). Above deep bluish black with white fringes, a carmine ring at the neck, palpal base and abdominal end; the sides of the abdomen are striped yellow, the costal margin of the hindwing beneath is narrowly orange-yellow, which colour extends as a fine marginal line before the fringes as far as near the anal angle. Colombia, Brazil, also in numbers from West Mexico (Guerrero).

A. amra *Hew.* (= *brasiliensis Mab.*) (166 c) differs from the preceding by red-striped abdominal sides and by the yellow marginal band of the hindwing beneath being broader than the fringes. Brazil.

A. proxima *Mab. & Boull.* has red-spotted abdominal sides and a red costal margin of the hindwing beneath; the marginal band before the fringes on the hindwing is of the double width of the fringes. The species is besides by one third larger than *amra*. Distributed from Mexico through Colombia as far as Paraguay.

A. ambigua *Mab. & Boull.* exactly resembles *Mysoria venezuelae* (162 h) and is only discernible by the veins. It has the broadest marginal band of the hindwing, which is more than twice as broad as the fringes. Brazil.

3. Genus: **Mysoria** *Wts.*

Entirely like the preceding genus in the structure except the petiolation of the upper median and lower radial vein of the hindwing, rising from above the lower cell-angle; the posterior tibiae are likewise bare.

M. sejanus *Hpfgr.* (162 g) is above dull bluish-black with a red abdominal end; hindhead, collar and first joint of the palpus are black. Beneath the costal margin of the hindwing is not differently coloured. Bolivia.

M. thasus *Cr.* (162 h) is just the same but it has a red spot on the hindhead and on the middle of the collar, and a red first palpal joint. Colombia and Peru.

M. pallens *Mab.* is similar, but it has beneath in front of the white fringes of the hindwing a yellow marginal band. From Brazil.

M. decolor *Mab. & Boull.* differs from the preceding by the white marginal band of the hindwing being strewn black, instead of the yellow one, exhibiting traces of a red costal margin of the hindwing. Costa Rica and Panama.

M. venezuelae *Scudd.* (= *acastus auct. nec Cr.*) (162 h) has on the under surface a red costal margin of the hindwing, which grows a little broader towards the base, and a yellow marginal band before the white fringes, which gradually grows narrower towards the anal angle. The fringes of the forewing are of a pure white as far as the apex. Distributed from Mexico to Colombia.

M. cayennae *Mab. & Boull.* differs from the preceding species by the fringes of the forewing being blackened from the upper median vein to the apex, and besides the red costal margin of the hindwing beneath is equally broad as far as the base. — In the form **verbena** *Btlr.* (= *phidias F.*, *barcastus Sepp*) the otherwise yellow marginal band of the hindwing is red, like in: **acastus** *Cr.* in which form the red at the costal margin of the hindwing is extinct. Guiana.

4. Genus: **Yanguna** *Wts.*

This genus contains large, very strong animals. On the forewing the upper median vein rises far behind the middle of the cell, both the lower subcostal veins rising separately; on the hindwing the cell is longer than

half the costal margin, the middle radial is absent; the distal margin is feebly undulate or somewhat concave. The posterior tibiae show 2 pair of spurs.

- spatiosa.* **Y. spatiosa** Hew. (164 b) is a large beautiful species, black with a deep hemochrome base of the forewing and a larger discal spot of the hindwing, also the thorax and base of abdomen are intermixed with red hair. The forewing exhibits a broad tripartite band of vitreous spots in the middle and 2 shorter and narrower ones behind it, often between the second and third besides 2 minute vitreous spots; the under surface is dull lustrous indigo-blue with a red diffuse spot at the base of the hindwing. Ecuador, Colombia.
- cosyra.* **Y. cosyra** Drce. (164 b) differs from the preceding by yellow-red and less extensive basal spots; the 2 hyaline dots between the apical and postdiscal bands are always absent; the abdomen is more conspicuously curled whitish. Bolivia and Peru.
- staudingeri.* **Y. staudingeri** Plötz (164 b) is likewise very similar, but it has only 2 small hyaline spots, the discal one of which is shorter and broader; the basal spots are of a purer red, the under surface of a brighter metallic blue. In the form: — **cometides** Stgr. (164 b) the apical hyaline spots are also absent, so that there only remains the large discal hyaline spot, and besides the red colour is mostly more or less confined and may be entirely absent on the wings. From Peru and Bolivia.
- aspilos.* **Y. aspilos** Mab. & Boull. (164 b) is without any hyaline spots, it is entirely bluish-black with yellow-red basal spots. Peru, Bolivia.
- cometes.* **Y. cometes** Cr. (= *thelersa* Hew.) resembles *staudingeri* (164 b) above and has also only 2 rows of hyaline spots, the insignificant basal spots are rusty-red. Beneath distinguishable by its reddish ground-colour with black marginal spots on the hindwings, 2 or 3 of which at the proximal angle are pupilled white. Surinam.
- aspitha.* **Y. aspitha** Hew. (164 c) is very much like *cometes*, but it has only one small apical hyaline spot and yellow-red basal spots; the abdomen is curled white like in *cosyra*. Pará.
- rubricollis.* **Y. rubricollis** Sepp (164 c) has on the black wings only one tripartite hyaline discal spot, a black head and abdomen and red-spotted shoulders. Surinam.
- pedaia.* **Y. pedaia** Hew. (164 c) differs from *rubricollis* by its red head and apex of abdomen, whereas the shoulders remain black. Amazon.
- hadora.* **Y. hadora** Hew. (164 c) is the same, but it has a black abdominal apex, a red prothorax, and on the red head a black transverse streak between the eyes. Ega.
- arinas.* **Y. arinas** Cr. (= *arinus* F.) (164 c) has a more intense blue lustre on the wings, with a more rounded oval, hyaline discal spot; only the frons and apex of abdomen are black. Fringes of the hindwings white. Surinam.
- assaricus.* **Y. assaricus** Cr. (= *alsarius* F.) (164 c) is a smaller, somewhat more variegated species; beside the white discal band of the forewing it has 3 apical hyaline spots and 3 before them, with a red-spotted base; base and disc of the hindwing are red-brown with 2 black spots in it near the proximal margin; the fringes of the hindwing are speckled white. On the under surface the hindwings are spotted blue and white. The abdomen is red and black, with whitish rings and a red end; the head is black. Guiana.
- parima.* **Y. parima** Plötz (164 d) is likewise smaller and neater with a very concave excision of the distal margin of the hindwing. The black forewing exhibits beside the orange-red discal band two rows of hyaline spots, the hindwing a large red anal-angular spot. Thorax and head likewise red-yellow. Surinam to Bolivia.

5. Genus: **Mahotis** Wts.

Closely allied to the preceding genus, but it has only terminal spurs on the posterior tibiae, and the cell of the hindwing is shorter and does not reach the middle of the wing, the distal margin of the hindwing is entire and round; the upper median and lower radial vein rise together from the lower cell-angle or also short-petioled.

- crida.* **M. crida** Dbl. (164 e) may not belong here at all. The wings are black with a discal spot; head and apex of abdomen red. Nicaragua.
- nurscia.* **M. nurscia** Swns. (164 d) is above black with a large, brick-reddish, somewhat transparent discal spot, the hindwings have some blue macular markings particularly towards the distal margin. Beneath the hindwings are blue with a black marginal band and 2 black basal rays. Ecuador and Peru.
- malis.* **M. malis** G. & S. (164 d) is above very similar, but beneath quite different, the hindwings being black with 3 blue transverse bands, the middle one of which consists of separate spots. Colombia.

6. Genus: **Ardaris** Wts.

Distinguished from the preceding genus by a well developed middle radial of the hindwing, rising from the middle of the transverse vein. The posterior tibiae likewise show only 1 pair of spurs. Only 1 species:

A. eximia Hew. (164 e) is a smaller, very easily recognizable species, above black with an oblique *eximia*. band of 7 reddish-yellow spots and one behind the cell; the hindwings are diaphanous light yellow, in the disc with a slight red-brown tint and a black marginal and discal band. Venezuela.

7. Genus: **Metardaris** Mab.

Very much like *Ardaris* from which it differs by 2 pair of spurs of the posterior tibiae, and the middle radial of the hindwing rising nearer to the lower radial vein. Likewise only one, though variable species:

M. cosinga Hew. (164 e) has light-yellow, more or less grey-dusted forewings with thick black *cosinga*. veins, a broad black distal margin and a dentate discal band interrupted between the median veins. The long-haired black thorax shows 2 light-yellow longitudinal stripes; head red, with black spots, anal tuft red. — f. **obscura** Mab. has entirely black wings, the light yellow patches are visible only beneath. — In f. **sanguinea** *obscura*. *sanguinea*. Mab. the cell-spaces are of a deep red instead of light yellow. Bolivia. Peru.

8. Genus: **Granila** Mab.

Greatly approaches the following genus *Jemadia*, also exteriorly with respect to the colour and marking. The chief difference is the petioled rise of the upper median and lowest radial vein from above the lower cell-angle on the hindwing. Only one, sexually somewhat dimorphous species:

G. paseas Hew. (= ♀ *albimacula* Mab. & Boull.) (163 a). Above black with light-blue dusting *paseas*. at the base, oblique subbasal band and antemarginal spots; the discal oblique band and 2 spots towards the apex are light yellow in the ♂, white in the ♀, like an oblique band in the costal-marginal area of the hindwing. From Brazil.

8. Genus: **Jemadia** Wts.

A very comprehensive genus, in which it is rather difficult to define the species owing to the extraordinary resemblance among one another. Moreover, there are 2 series parallel to each other, one of which shows 4 white dots on the prothorax, the other exhibiting a white transverse streak instead. In order to facilitate the definition we keep to MABILLE's division of the groups into „*punctati*“ and „*lineati*“. The *Jemadia* are robust animals with white or blue marking and hyaline spots. The hindwings are often remarkably small, in the ♂♂ often with tooth-like projections on the inner-marginal and lower median vein, above them mostly with a deeply concave excision, and between the upper radial and subcostal vein often with an obtuse projection; more rarely the hindwings are quite round. The middle radial vein is absent, the lower one comes from the lower cell-angle, the upper median vein below it separately.

I. Group: **punctati**. Prothorax with 4 bluish-white dots beside each other.

J. hospita Btlr. (166 b) has, like the following species, a rather round, only feebly undulate distal *hospita*. margin of the hindwing. A characteristic mark of this species is the hindwing exhibiting on its black ground only one blue discal band and 3 fine, blue inner-marginal rays; the latter are all developed the same, diverging distally, the most proximal ray, extending to the proximal margin, is parted by a fine black longitudinal stripe. From Colombia and Brazil. — f. **pseudognetus** Mab. from Colombia is larger, the blue oblique stripes at the *pseudognetus*. base of the forewing are extinct, the narrow marginal band coherent; on the hindwing the most proximal ray of the inner-margin is shorter than the middle one. — f. **imitator** Mab. (163 c) (= *dorylas* Plötz, *vulcanus* Hew., *imitator*. *paulensis* Schs.) from Bolivia is above much blacker, the basal bands of the forewing quite extinct or absent, the marginal band broken up into spots; the postdiscal hyaline spot is absent altogether, or it is replaced by 2 minute hyaline dots. On the nearly quite black hindwing the middle inner-marginal ray touches the marginal band. — f. **ulyxes** Plötz (163 c) represents the species farther up to the north as far as Surinam; on the forewing *ulyxes*. the basal oblique band is extinct, the distal one quite narrow and slightly concave distally; the marginal band extends coherently to the postdiscal hyaline spot, then it makes a break and forms 2 small spots as far as the small apical spots; the inner-marginal rays of the hindwing are strong and broader than in the other forms. — Although these 4 forms are reported to exhibit slight differences of the sexual organs, yet I should take them to be a very variable species; the separation grows still more difficult, if there are very large

series spread before one, as for instance from FASSL's collection; then the differences become more and more obliterated.

vulcanus. **J. vulcanus** Cr. nec (Hew. 163 e) has a blue band more on the hindwing than the preceding species, the most proximal of the inner-marginal rays being removed more into the middle and forming a broad middle-band. On the forewing the basal bands are both well developed, the marginal band runs in a straight line to the apical hyaline spots and even beyond them. Colombia, Guiana.

hewitsoni. **J. hewitsoni** Mab. (166 b) looks like the preceding, but the middle band of the hindwing is only very short, triangular and almost white. Beneath on the hindwing the 2 black middle bands are united at the costal margin and proximal margin, the latter being all black. Colombia.

fallax. **J. fallax** Mab. (163 e) likewise resembles *vulcanus*, but it can easily be distinguished from all the species of the *punctati*-group by the distal, basilar band of the forewing forming with the lower blue inner-angular streak a single oblique band; the fine marginal band is somewhat more curved. On the hindwing the blue median band is removed more distally, the marginal band being narrow, broadly interrupted by the black veins. The under surface of the hindwings is almost entirely black, the broad black middle bands exhibiting only a fine metallic bluish-green thread between them. Brazil, Colombia.

patroclus. **J. patroclus** Plötz (166 c), according to the excellent figure by PLÖTZ, belongs to the *punctati*, not as MABILLE thought to the *lineati*, the species being allied to *fallax* from which it chiefly differs by the distal basal oblique band of the forewing not coalescing with the inner-marginal ray, but being separated afar. On the forewing there is only a small, square, postdiscal hyaline spot, above it there is a small blue oblique spot; the 5 apical hyaline spots are relatively large and well developed. The hindwings are marked the same, but the blue marginal band is considerably broader and coherent. On the under surface the 2 black middle bands are separated afar by the blue colour and neither coalescent at the costal margin; before the black border, in the blue colour, there is besides a fine, black, undulate line from the upper median vein to the costal-marginal vein. Described from Peru.

lisetta. **J. lisetta** Mab. & Boull. In the following species of this group the distal margin of the hindwing, at least in the ♂, is deeply concave with 2 distinctly dentate anal lobes, in the ♀ mostly rather rounded. In *lisetta* the marginal band of the hindwing consists only of 4 or 5 separate, small spots and does not extend to the proximal angle; the blue middle band is entirely absent. Described from Peru.

lecerfi. **J. lecerfi** Mab. & Boull. (163 d) has a still shorter marginal band of the hindwing, extending only to the lower median vein, and a short, triangular, pale blue median band. On the forewing above the blue marginal band only extends to the postdiscal hyaline spot. Guiana.

menechmus. **J. menechmus** Mab. (163 d) differs from the two preceding by a broader, coherent marginal band exhibiting a break only near the proximal angle. The blue marginal band of the forewing extends to the small apical hyaline spots. Brazil and Colombia.

gnetus. **J. gnetus** F. (= megalesius Hbn., sosia Mab.) (163 d) has been a somewhat doubtful species which I, however, unhesitatingly unite with *sosia*; it has the broadest marginal band of the hindwing, extending coherently to the proximal angle where it bends round and passes over into the inner-marginal ray; the two proximal inner-marginal rays are flown together to a broad, white-blue surface, the median band is absent. On the under surface the 2 black median bands are not directly united at the proximal margin, only coalescent at the costal margin. Widely distributed in Colombia, Guiana and Brazil.

hephaestus. **J. hephaestus** Mschr. (= zamorae Mab.) (163 e) is very similar, on an average somewhat smaller, above with a narrowed marginal band and middle inner-marginal rays, the median band being likewise absent. The under surface of the hindwing shows an entirely black proximal margin and the 2 black median bands are also united at the proximal margin. From Surinam as far as Colombia and Bolivia.

II. Group: *lineati*. Instead of the 4 dots at the prothorax a bluish-white transverse line.

polyzona. **J. polyzona** Latr. (= jamina Btlr.) (163 a) is easily recognizable by the great extent of the blue colour, particularly the blue costal margin, the postdiscal hyaline spots being scalariformly arranged below each other, and 4 apical spots. On the hindwing beneath the middle black band is forked like a Y on the middle radial. Guiana and Brazil.

zimra. **J. zimra** Hew. (163 a) is similar, but much less blue, mostly with an intensely greenish tinge; particularly the marginal band of the hindwing is very narrow. Brazil to Paraguay.

alburnia. **J. alburnia** Mab. (163 b) has above no blue rays or only traces of them below the median hyaline spot of the forewing, and beneath the black median band of the hindwing is not shaped like a Y, but broadly coalescent with the proximal one at the costal margin and proximal margin, like in the *hospita* group. Brazil.

J. zonara Hew. (163 b) has, like *fallax* (163 e) of the first group, the distal oblique band of the forewing connected with the lower blue inner-marginal spot and round the proximal angle mostly continued as far as the marginal band. The black median bands of the hindwings beneath are on both sides coalescent. The species is more common, flying from the Amazon through Colombia as far as Ecuador.

J. suzetta Mab. & Boull. is larger than *zonara*; the 2 blue stripe-like spots below the median hyaline spot are broad, connected at the apex and separated from the broad, distal, basilar oblique band. Bolivia.

J. macleannani G. & S. (166 b) differs from the preceding by the Y-shaped, black median band of the hindwing beneath, the absent or almost extinct postdiscal hyaline spot of the forewing and blue proximal margin. Panama.

J. umbrata Mab. & Boull. Whilst the preceding 6 species show 4 small, apical hyaline spots, there are here and in the following species 5 of them. The median hyaline spot is broadly square, above it there is another 4-cornered blue spot; the blue marginal band extends to the postdiscal hyaline spot. Beneath the proximal margin is quite black, the black median band on the subcostal vein forked in the shape of a Y. Bolivia.

J. patrobas Hew. (= *vulcanus* Hew. [text]) (163 b) differs from *umbrata* by more blue at the proximal margin of the hindwing beneath, as well as by the bifurcation of the black median band taking place already below the upper radial vein. Brazil and Colombia.

J. azeta Hew. (163 b) has a still more extensively blue proximal margin of the hindwing beneath, and the Y-shaped bifurcation of the black median band takes place already at the upper median vein or even below it. — In f. *melanina* Mab. (163 c) the black of the under surface is very extensive. Bolivia to Paraguay.

J. brevipennis Schaus is unknown to me, it may belong near *zimra*; spots and bands decidedly green; instead of the 2 postmedian hyaline spots of *zimra* there is but one; the median band of the uncommonly short hindwing is reduced to a green cell-end streak. Described from São Paulo.

J. ahira Hew. (163 a) is easily recognizable by the absence of all the hyaline spots and by the broad, bluish-green inner-marginal band of the forewing. Pará.

10. Genus: **Nosphittia** Mab. & Boull.

By the habitus, colour and marking this genus entirely approximates *Jemadia* from which it chiefly differs by the posterior tibiae being without any spurs, but fringed above. Furthermore, as a unique mark of the whole family, the rise of the lower radial vein from the upper median vein on the hindwing is as equidistant as the upper median vein from the lower one. The distal margin of the hindwing is somewhat concave, the anal lobe well developed. Hitherto only one very imposing representative known:

N. perplexa Mab. (= *scomber* Drc.) (163 c) looks exactly like a gigantic *Jemadia*, also in the colouring and marking. The distal blue basilar oblique band of the forewing passes over into the lower inner-angular spot, like in *J. zonara* or *fallax*, and from there it turns round without any interruption into the marginal band which reaches as far as the apical spots. On the hindwing the inner-marginal rays form a broad white patch, the median band is represented by a large blue spot. On the collar a white stripe, no dots. Brazil.

11. Genus: **Sarbia** Wts.

A very uniform group of black, imposing animals marked yellow and red, with entire-margined wings and a rather pointed apex of the forewing. On the forewing the lower median vein rises close at the base, the upper one behind the middle. The hindwing is very feebly undulate at the border; the discocellular is shorter than half the length of the wing; the upper median vein rises petioled with the lower radial. The posterior tibiae have two pair of spurs.

S. spixii Plötz (164 f). On the black forewing the spot below the cell of the broad yellow median band touches the lowest of the 6 yellow apical spots; at the base of the forewing there is above the proximal margin a minute yellow spot. The hindwing exhibits a broad yellow discal area which is divided on the transverse vein by a black transverse stripe cohering with the broad black proximal margin. Palpi, anus and venter are red, the latter with a black streak before the last ring; abdominal sides, shoulders, and a stripe on the shoulder-covers are yellow. Patria doubtful.

S. xanthippe Latr. (164 f) was described according to but one ♀ and is above almost just like *spixii*, though the basal spot of the forewing is smaller, the yellow bands of the forewing do not touch each other, and the base of the hindwing is extensively black. Beneath on the hindwing the black stripe of the transverse vein is a broad band; the red venter exhibits a black streak in the middle, so does the red hindhead. Rio de Janeiro.

- oneka*. **S. oneka** *Hew.* has no basal spot of the forewing; the yellow bands of the forewing are very narrow and consist of separate spots; on the hindwing the 5th and 6th spots of the yellow band, counting from the proximal angle, are removed towards the base. The under surface of the hindwing is preponderantly black with 2 yellow spots at the base. The red head is posteriorly bordered with black; the black abdomen shows beneath a yellow stripe, the sides being red. Ecuador.
- antias*. **S. antias** *Fldr.* (164 f) has somewhat broader yellow bands than the preceding, red palpi and collar, the head being otherwise black. The venter is striped red. Brazil.
- erythro-*
soma. **S. erythrosoma** *Mab.* (164 f) is immediately recognizable by the red 4 last abdominal rings being narrowly bordered with black; the short apical band runs straight. Amazon.
- damippe*. **S. damippe** *Mab. & Boull.* (164 f) is above similar, but it has a black abdomen, the venter being black, too, with double red macular bands; the sides exhibit small yellow-red spots. The hindwings are beneath black with a broad, regular median band and a four-cornered basal spot from the costal margin to the middle of the cell. Head red, between the eyes spotted black. Brazil.
- catomelaena*. **S. catomelaena** *Mab. & Boull.* is distinguished by an entirely black abdomen with a blue lustre, the venter being red only on the first rings; head and palpi are red, the hindhead striped black. Wings marked very much like in the two preceding. Minas Geraes.
- hegesippe*. **S. hegesippe** *Mab. & Boull.* has broader yellow bands on the wings, touching each other like in *spixii* (164 f). The hindwing beneath exhibits a yellow subbasal band being broad at the costal margin and tapering downwards, and a broad, regular median band. Head, anterior femora, and anus are red; the venter is bluish-black, the shouldercovers and the hair on the posterior tibiae are yellow. Guiana.
- pertyi*. **S. pertyi** *Plötz* (164 f) is very similar, but it has a red venter with a black median stripe and yellow lateral spots separated from the red by a black stripe. The red head shows a black transverse stripe between the eyes; the shoulder-covers are inside only narrowly margined with yellow. Brazil.
- martii*. **S. martii** *Plötz* (164 e). Here the distal band, running about parallel to the margin, extends down to the proximal angle; a large yellow basal spot is to be seen on the forewing; the hindwing shows a very broad median band projecting distally between the upper median and middle radial vein. The fringes of the hindwings are yellow, almost unspotted. Brazil.
- luteizona*. **S. luteizona** *Mab.* (164 b) is very similar, but it has black-speckled fringes on the hindwings, the still broader median band of the hindwing is distally somewhat blurred. Described from Mexico.

12. Genus: **Mimoniades** *Hbn.*

Large strong animals, the marking of which, on a black ground, corresponds to that of *Jemadia*, but the colour of the bands is a lighter or darker yellowish red, often with a brownish tint. The distal margin of the hindwing is only feebly undulate, but near the anal angle somewhat more distinctly dentate. On the forewing the lowest subcostal vein and the uppermost radial vein rise from the same place; the cell is shorter than half the costal margin, the transverse vein runs rectilinearly, the upper median and lower radial rise from the lower cell-angle.

- ocyalus*. **M. ocyalus** *Hbn.* (iphinous *Ky.*) (166 c) recalls *Mahotis nurscia* and *malis* (164 d). The black wings exhibit 3 brick-reddish, semi-diaphanous spots, the hindwing shows bluish bands at the proximal margin and distal margin. Brazil.
- eupheme*. **M. eupheme** *G. & S.* (163 f) is very variegated like the following: next to the base of the forewing is a blue band, then a broad red one in the middle, 2 spots nearer to the apex are yellowish-red; the hindwing exhibits 2 irregular blue bands. Anal apex black-haired. Peru, Ecuador.
- versicolor*. **M. versicolor** *Latr.* (= *mulcifer* *Hbn.*) (163 e) is similar, but the blue basal band is broader, the red median band narrower; above all distinguished by the red-haired apex of the abdomen. Brazil.
- sela*. **M. sela** *Hew.* (= *pityusa* *Hew.* pro parte) (163 f). Here and in the next species the forewing exhibits 4 red-yellow bands; recognizable by the under surface of the forewing showing 3 blue-white bands near the base and a more purely blue band near the margin. New Granada.
- periphema*. **M. periphema** *Hew.* (163 f) is above similar, but on the hindwing it has besides a broad, red-yellow marginal band. The hindwings are red-yellow beneath, with two equally broad, black median bands and a blue band in the broad black margin. From Peru and Bolivia.
- pityusa*. **M. pityusa** *Hew.* (= *porus* *Plötz*) (164 a) is the same, but on the hindwing beneath the blue marginal band is absent, and the distal one of the black median bands is narrower than the proximal one. Colombia, Peru.

M. punctiger Mab. & Boull. (164 a as *punctigera*) is very much like *pityusa*; the median band of *punctiger*. the forewing is pointed towards the proximal margin; the hindwing exhibits a regular, curved median band; the shoulder-covers are distally broadly bordered with red-yellow. Colombia, Bolivia.

M. minthe G. & S. (164 a) differs by the absence of the apical spots, so that there are only three *minthe*. red-yellow macular bands. — In the form: **egena** Mab. & Boull. the two postmedian spots are likewise absent. *egena*. Bolivia.

M. mimetes Mab. Somewhat smaller than *ocyalus* (166 a) which it superficially resembles entirely, *mimetes*. though the position and shape of the spots are different. The orange spot which in *ocyalus* is between veins 3 and 4, is parted in two by vein 4. The apical band is curved, composed of 5 spots, whereas in *ocyalus* it consists of 4 spots. The blue and yellow stripes run likewise somewhat different in *mimetes*. Guiana.

M. baroni Mab. & Boull. differs from all the others by the forewings being strewn with yellowish- *baroni*. green scales and exhibiting 3 rows of spots; fringes and palpi are yellow; the median band of the forewing is more red. The hindwings are black with two yellowish-green discal bands. Ecuador.

13. Genus: **Croniades** Mab.

Differs from the preceding genus only by much longer hindwings with the anal angle extended like a tooth. Only three species are known:

C. machaon Dbl. & Hew. (164 b) shows 3 yellow-white bands on the black forewing, on the hindwing *machaon*. a broad, yellow median band and reddish-yellow fringes. Brazil, Rio Grande do Sul.

C. pieria Hew. (164 b) recalls again more *Jemadia* by the scheme of markings; the spots of the forewings *pieria*. are light lemon-coloured, partly diaphanous, the hindwings are red-yellow with two black median bands being united towards the proximal margin, and a black border. Amazon, Colombia.

C. auraria H. Drce. is very closely allied to *pieria*, the yellow marginal band of the forewing is broader, *auraria*. the black postmedian band of the hindwing much narrower and towards the costal margin almost extinct; the hyaline band of the forewing has a somewhat different shape and position, and the hindwing is beneath in the proximal half of a much deeper orange than in the costal half. From La Paz (Bolivia).

14. Genus: **Microceris** Wats.

The antennal club is decidedly more slender and more pointed than in the allied genera. The hindwings are not prolonged as they are in *Croniades*, but dentate at the border. On the forewings both the lowest subcostal veins are situate next to each other at their rise. Only 1 species:

M. variicolor Mén. (164 e) shows on the black ground towards the margin blue, deeply notched *variicolor*. lines, and discal and subapical yellowish macular bands. Anal apex, palpi, and stripes on the thorax are likewise ochreous yellowish. Minas Geraes.

15. Genus: **Agara** Mab. & Boull.

The only species has a still longer antennal club being pointed almost like a thread, so that one might be inclined to doubt whether it is a *Pyrrhopygina* at all. The hindwings are somewhat longer than in the preceding and deeply notched. Both the lowest subcostal veins of the forewing are close next to each other, the two median veins rise close beside each other.

A. pardalina Fldr. (164 g) is black, on the forewing with large, discal and smaller subapical hyaline *pardalina*. spots. Thorax and bases of wings red-brown, on the hindwing very extensive and spotted black. The hindwing beneath exhibits instead of the red-brown a bluish-white colouring and in it, towards the base, two black transverse bands. Colombia.

16. Genus: **Myscelus** Hbn.

Differs chiefly from the preceding genus by the shape of the hindwings: they are not so uniformly dentate, but more undulate, below the somewhat extended apex sinuous, between the anal angle and the next tooth likewise deeply concave; the antennal club is likewise slender and pointed.

- illustris.* **M. illustris** Mab. (164 g) has, like the following species, a round hyaline spot on the hindwing. The colour is a bright golden-yellow with thick black veins and on the hindwing with three spotted antemarginal bands interrupted by black. Peru and Bolivia.
- nobilis.* **M. nobilis** Cr. (= *salus* F.) (165 a) extremely resembles the preceding, the black veins of the forewing somewhat less thick, the black border broader and the 3 black bands of the hindwing are more regularly coherent, and on the median veins, the uppermost radial and the subcostal vein more strongly dentate towards the margin. From Surinam.
- hages.* **M. hages** G. & S. (165 a) has a much smaller hyaline spot of the hindwing, the 3 black bands of the hindwing being much less pronounced. Central America.
- amystis.* **M. amystis** Hew. (165 a) is not so bright yellow, with much finer black veins and a narrower black border, the 3 bands of the hindwing stunted, partly interrupted. On the much lighter yellow under surface the black lines are much finer and consist only of short, black streaks. From Peru, Colombia and Bolivia.
- orbis.* **M. orbis** Mab. (165 a) has a more brown colour, a broader black border of the forewing, particularly broader at the proximal angle, with medium-fine black veins and somewhat nebulous, irregular bands of the hindwing, that are partly connected with each other. The hyaline cell-spot of the forewing touches the inner-marginal vein, in *amystus* it does not. The under surface is yellowish-brown, on the forewing the black markings are almost entirely absent, on the hindwing they are fine, prominently black. From Brazil to Paraguay.
- epigona.* **M. epigona** H.-Schäff. (164 g) is similar, above more yellowish-brown, the border not so black, the lines of the hindwing of a clearer, more prominent black. Beneath quite light-yellow, almost without any black marking, also on the hindwings only light brownish traces of it. Venezuela. Perhaps the northern representative of *orbis*.
- sothis.* **M. sothis** Mab. (165 a) approximates particularly *phoronis* from which it chiefly differs by the under surface of the hindwing, in which the rusty brown ground-colour being broadly yellow at the base is traversed by 3 undulate brown macular bands, the two lower ones of which are nearer to each other, whereas *phoronis* has four black undulate lines at equal distances from each other. Brazil.
- aethras.* **M. aethras** Hew. i. 1. is dark brown with a broad, black border of the forewing. The hindwing shows 3 stout, coherent, black transverse bands being broadly separated from each other. On the under surface the bases of the wings are whitish, the hindwings exhibit distinctly marked transverse bands. Brazil.
- orthrus.* **M. orthrus** Hew. is more red-brown, the brown border of the forewing exhibits 9 white dots. The macular bands of the hindwing are not black, but more rusty brown. Brazil.
- phoronis.* **M. phoronis** Hew. (165 a). This well-known species is of a bright rusty yellow, the forewings almost without the dark border. The hyaline spot of the hindwing is very large, round, sharply defined with black. On the under surface the proximal halves of the wings are sharply defined by a light yellow, with the three usual transverse bands being brown here. Widely distributed in Colombia, Bolivia and Peru.
- belti.* **M. belti** G. & S. (166 c) differs by the darkened apical part of the red-brown forewing and a much smaller hyaline spot of the hindwing. Beneath the wings are lighter, the distal macular band of the hindwing touches the margin. Central America.
- persela.* **M. persela** Mab. (166 c) is above of a purer brown, beneath in the proximal halves of the wings light greenish yellow, marked similarly as *phoronis*, but the distal transverse band is situate nearer to the border and is more angular. Brazil. — In the form: **caucanus** Stgr. the under surface of the hindwing is without the black transverse band before the hyaline spot, and without the basal stripe; the distal part is so very much darkened, that the black band bordering on it proximally and the one being situate in it are scarcely prominent. The upper surface is also a little darker, of a more monotonous brown colouring than in *phoronis*. Cauca Valley.
- santhilarius.* **M. santhilarius** Latr. (164 g) has, like the following species, no hyaline spot of the hindwing. Above rusty brown with a broadly darkened border; the small subapical hyaline spots touch the discal spot by being moved forward towards the margin between the median veins. On the under surface the hindwing is yellow with 3 black bands and a broad black border. Guiana to Brazil, Amazon.
- epimachia.* **M. epimachia** H.-Schäff. (165 a) is above more purely rusty yellow without the darkened border of *santhilarius*. The discal spot is not so much pushed forward, the subapical spots do not touch it. The yellow of the hindwings beneath is purer, more extensive. The hindwings are more prolonged. Peru to Paraguay.
- pegasus.* **M. pegasus** Mab. (165 b) is smaller, more dirty rusty brown. The hyaline spots of the forewings are similar to those in *santhilarius*. The under surface of the hindwings is of a purer yellow, without any brown transverse bands, only discally there are occasionally traces of one. Palpi and legs are yellow. Guiana.

17. Genus: **Azonax** *G. u. S.*

Distinguished from the most closely allied genera by the entire-margined hindwings being only on the upper radial somewhat angular. The antennal club is obtuser than in the preceding, and in contrast with the allied genera the upper median and the lower radial of the hindwing are not petioled. 1 species:

A. typhaon *Hew.* (165 e) looks like a *Myscelus*: above rusty brown with one large, quinquepartite, *typhaon*. discal vitreous spot and 4 small apical ones, between them at the costal margin 2 more of them. The hindwing exhibits one large, round, white antemedian spot and a row of black dots behind it, two of which are pupilled white. Nicaragua.

18. Genus: **Oxynetra** *Fldr.*

Differs from all the other *Pyrhopyginae* by the straight transverse vein of the forewing. On the hindwing the middle radial vein is absent; the antennal club is rather pointed.

O. felderi *Hpff.* (165 b) is like the other very similar species of a greenish black with very large *felderi*. vitreous spots. The present species has a red ring round the 2nd abdominal segment. On the forewing the very large discal hyaline area is separated from the subapical one only by a small, narrow black stripe. Brazil to Peru.

O. semihyalina *Fldr.* (165 b) has no red-brown abdominal ring and a very much larger subapical *semihyalina*. vitreous spot separated from the discal one by a broad black band. Towards the margin on the veins pearl-coloured dust-stripes. Body and mesothorax are metallic green. Colombia.

O. confusa *Mab.* (= *annulata* *Stgr.*) (165 b) is similar, but the subapical vitreous spot is oval, not *confusa*. square as in the preceding, parallel with the margin there is behind it a band dusted with a pearl-colour, growing narrower towards the proximal angle. The ♀ described as *annulatus* has quite black wings without any vitreous spots and a red-ringed abdomen. Described from Peru.

O. hopfferi *Stgr.* (165 b) differs from the preceding by a much narrower vitreous band of the forewing, *hopfferi*. being only traversed by the median and its branches, by the absence of a white spot below the large double vitreous spot of the hindwing, and particularly by 5 bright orange-red transverse band on the dorsum of the abdomen; venter in the middle curled white. Shoulder-covers spotted orange. From the Chiriqui.

Subfamily: **Hesperiinae** *Wts.*

A large subfamily with not always uniform marks, so that a separation into two groups was necessary, so as to arrange in some degree the great number of forms. There are very large animals with extreme resemblances to certain genera of the *Pyrhopyginae*, down to small species. All have either a very short or horizontally projecting 3rd palpal joint, which is never bent up vertically. On the forewing there is never a discal stigma.

Group A.

The species of this group mostly have the antennal club bent round like a hook, sometimes in the shape of a sickle always terminating into a fine point. The chief mark of distinction from the 2nd group is the length of the cell of the forewing, always amounting to more than $\frac{2}{3}$ of the length of the costal margin. The transverse vein generally runs very obliquely; the middle radial vein never rises very near to one of the neighbouring branches. On the hindwing, often exhibiting a tail or a tooth on the submedian vein, the middle radial vein is always rudimentary. The ♂ usually exhibits on the forewing an inverted costal-marginal fold which is inside covered with scent-scales, often a hair-tuft on one of the wings or on the tibiae mostly having two pair of spurs, and a spine on the anterior tibiae. This group is almost exclusively confined to the nearctic region, only very few species being found in the old world.

1. Genus: **Phocides** *Hbn.*

Distinguished by a spindle-shaped antennal club on which only the fine tip is turned round like a hook. The thickly scaled 2nd palpal joint, being closely appressed to the forehead, is of a broad square shape, the very short 3rd joint being scarcely visible. The lower discocellular of the forewing is the longest and strongly curved. The lower median vein rises twice as far away from the upper one as from the base, the upper one close before the cell-end. The hindwing is much prolonged towards the anal angle, but it does not show a real tail. The tropical parts of South America homes about two dozen of species.

Ph. oreades *Hew.* (165 e) resembles about *Mimoniades sela* (163 f), but in the basal area of the forewing *oreades*. there are, like in all the convergent *Hesperiinae*, longitudinal rays, in contrast with the basal transverse bands

- of the corresponding *Pyrrhopyginae*. These rays are partly bluish-green like the marginal spots of the hindwings.
- oreas*. The under surface, however, almost entirely corresponds to that of *sela*. Peru. — *oreas* *Stgr.* from Bolivia has broader bands, which are yellowish-red also on the hindwing. — *debora* *Stgr.* has quite light yellow bands.
- charonotis*. **Ph. charonotis** *Hew.* (165 e) differs from *oreades* by quite green basal rays of the forewings, without any yellowish-red, and much more extensive red-yellow bands of the hindwings, which are also beneath of the same colour, not blue. Bolivia.
- yokhara*. **Ph. yokhara** *Btlr.* (165 e) is similar, but it has quite red-yellow basal rays of the forewings, the yellowish-red colour of the hindwings is still more extensive, and the black ground-colour on the upper and lower surface of the forewings is suffused with a coppery brown. Magdalena River, Peru.
- pialia*. **Ph. pialia** *Hew.* (165 e), in contrast with the preceding, is banded almost quite greenish-blue, only the 3 large discal and apical macular rows remain red-yellow. Distributed from Mexico through Guatemala as far as Brazil.
- lilea*. **Ph. lilea** *Reak.* (= *albicilla* *H.-Schäff.*, *cruentus* *Scdd.*, *socius* *Btlr. & Drc.*, *decolor* *Mab.*, *denuba* *Plötz*) (165 d) is a dark species, above and beneath black with a red discal streak of the forewing, above in the basal half tinted greenish-blue. Palpi and neck orange-red, fringes white. Like *pialia* most widely distributed from Mexico to Brazil.
- palemon*. **Ph. palemon** *Cr.* (= *polybius* *F.*, *cruentus* *Hbn.*, *spurius* *Mab.*, *phanias* *Burm.*) (165 d as *spurius*) is very similar, but in the anal part of the hindwing it has broad, orange-yellow fringes. Brazil to Argentina.
- unimacula*. — **unimacula** *Mab. & Boull.* has only one red cell-spot, the costal part being absent.
- imbreus*. **Ph. imbreus** *Plötz* (165 f) resembles *lilea* (165 d), but instead of the red discal streak it has a metallic blue one, and the ring round the neck is not orange, only the palpi. Central America.
- charon*. **Ph. charon** *Fldr.* from Brazil approximates *palemon* (165 d as *spurius*); of a blackish-green lustre, costal margin and base of the forewing strewn with lighter atoms, the fringes posteriorly white; beneath the base is sooty brown with a blue proximal margin, 3 spots at the base of the costa and the dusting at the costal margin whitish-green. Hindwing on both sides bluish, the costal and proximal margins violettish-blue, fringes at the apex white, at the hinder angle yellow; beneath of a lighter lustre, with a dispersed basal and discal strewing.
- tophana*. **Ph. tophana** *Plötz* (= *scythron* *G. & S.*) (165 d) likewise resembles *palemon* regarding the ochreous-yellow anal-angular fringes on the hindwing, but it has no discal streak at all on the black forewing, showing but very little green reflection at the base. Minas Geraes, Peru, Uruguay, Paraguay.
- distans*. **Ph. distans** *H.-Schäff.* (165 e) from Central America, Colombia and Cuba entirely resembles a *Jemadia*, but, like in *oreades*, instead of the *Pyrrhopyginae*-transverse bands it has basal longitudinal rays of the forewing. This species and the 4 following are very much alike and are often confounded. It is best distinguished on the hindwings beneath: *distans* shows here 3 blue bands, the middle one being short, extending only to the middle of the wing, equally distant from the two others, the most proximal one being at the same time the shortest. *PLÖTZ*' figure of the supposed *Jemadia dysoni* from the Chiriqui, in spite of the *Pyrrhopyginal* antennae, I can only take to be a *Phocides* with a wrong head, on account of the basal longitudinal rays; it entirely resembles *distans*, and is only of a somewhat purer blue. — **tenuistriga** *Stgr.* is larger, more extensively black, the discal band almost as narrow as a thread.
- pigmalion*. **Ph. pigmalion** *Cr.* (= *gnetus* *Latr.*) (165 e) is a larger, robust species. On the hindwing beneath the blue median band is thin, almost like a thread, bending outward at the lower end and touching the broad, spotted distal band in its middle; the latter band is shorter than the proximal band. The blue basal rays above are short. Colombia.
- belus*. **Ph. belus** *G. & S.* (165 f) entirely resembles *valgus* (161 a), but the 3 hyaline bands of the forewing are more compact and are placed more steeply, the proximal one ending broader on both sides, whilst in *valgus* it is tapering towards the hinder angle. From Mexico.
- perillus*. **Ph. perillus** *Mab.* I only know from the insufficient description and uncoloured figure: it is above black with the usual 3 hyaline bands, the apical and postdiscal ones of which are situate close together and both very large; the text does not mention any blue colour on the forewing, according to the figure, however, it is extensively present in the basal area and in marginal spots. The hindwing exhibits, parallel with the distal margin, a broad band of 8 blue spots, a broad discal ray and a triangular patch of whitish-blue at the base. Beneath similar to *distans*. From Colombia.
- valgus*. **Ph. valgus** *Mab.* (161 a) differs above from *pigmalion* by much stronger and longer basal rays extending almost to the discal vitreous spot, the blue colour being at any rate much more extensive. On the hindwing beneath the blue middle band is almost purely white, longer and broader, only below the broad proximal band

somewhat curved, without touching the distal band which is parted into 4 spots and ends pointedly on the upper median vein. From Cayenne.

Ph. thermus *Mab.* is immediately discernible by only 2 hyaline bands on the forewing above: an *thermus*. apical one, and a discal one, extending as a band up to the costal margin; the only remainder at most of the postdiscal band may be a small vitreous dot above the lower radial vein. Beneath like *pigmalion* (165 e), the basal band almost straight, the middle one narrow, longer, not touching the distal one, which is short and ending at the middle of the median. Bogotá.

Ph. hewitsonius *Mab.* (= *pygmalion* *Hew.*) is a doubtful species showing above long, blue basal *hewitsonius*. rays like *valgus* (161 a); the hyaline spots are uncommonly large and a little differently placed; it presumably coincides with one of the preceding species. The under surface is unknown.

Ph. batabano *Luc.* (= *mancinus* *H.-Schäff.*) (165 d) is not to be confounded with any other species. *batabano*. Above dark slate-brown, at the bases of the wings striped bluish-grey, and in front of the margin of the hindwing with an undulate line of bluish-grey. Beneath the hindwing shows yet 2 or 3 narrow blue stripes in the middle and near the proximal margin. Cuba.

Ph. urania *Dbl. & Hew.* (165 f) is very well recognizable by the long, bluish-green internerval stripes *uranias*. extending almost to the border. Common in Mexico. — **pyres** *G. & S.* is of a more brilliant green, the subterminal band, which in the form *texana* *Scudd.* is yellowish-brown, being coherent. *pyres*. *texana*.

Ph. vida *Btlr.* (165 f) is the same, but without any hyaline macular bands at all, so that there is a *vida*. broad, black apical area. Panama and Costa Rica.

Ph. lincea *H.-Schäff.* (= *grandimacula* *Mab.*). Above slate-coloured with a slight olive tint, similar *lincea*. to *Nascus phocus* (169 f) towards the base somewhat lighter, distally bordered darker with 3 hyaline bands placed like in *uranias* (165 f), but much broader, the discal one extending to the costal margin and here with a yellow tint. The hindwing exhibits a dark median band forking towards the costal margin. Beneath the forewings are lighter, towards the base yellowish, the hindwings reddish-yellow with 3 dark bands. Described from Brazil.

Ph. iphinous *Latr.* is a species having for a long time been erroneously taken for another, resembling *iphinous*. *oreades* (165 e) on the forewings, but the basal rays are entirely absent, and the brick-reddish discal band is above and beneath of the same with, something like in *nurscia* (164 d). The hindwings are likewise quite black, with only one narrow blue subterminal band and a similar blurred spot at the proximal margin. Brazil.

Ph. thrasea *Hew.* (= *mazares* *Mab.* [*Stgr. i. l.*]), a small doubtful species, is above black with a *thrasea*. steel-blue reflection, at the apex of the forewing brownish, in the apical part of the forewing, and at the anterior angle and border of the hindwing beneath light violet. Head and palpi, collar and shoulders, as well as the apex of the abdomen of a deep dark red. Epanse of wings: 35 mm. South America.

Ph. maximus *Mab.* is only known to me from the description and figure: Above black, the spots *maximus*. of the forewings diaphanous reddish-yellow, the discal ones below the cell much broader; hindwing with 3 blue rays and an antemarginal row of blue crescents. This species on the whole recalls *Mimoniades versicolor* (163 e), but it is much larger. Brazil.

Ph. nakawara *Weeks* almost coincides with *distans* (165 e) in the description, but there is only one *nakawara*. white apical spot mentioned on the forewing, and on the hindwing the triangular blue median band is absent. 55 mm. From Venezuela.

2. Genus: **Tarsoctenus** *Hbn.*

Closely allied to *Phocides* from which the species differ by the 3rd palpal joint projecting a little more and being bare; besides the transverse vein of the forewing is not so oblique, and the middle discocellular is somewhat longer than the lower one; the hindwings are here also longer and extended into a round anal lobe. In the ♂ one of the two spurs of the posterior tibiae is prolonged, and the proximal end of the tarsus shows on each side beneath a comb of yellowish bristles, covering this spur when the tarsus is stretched out. In *papias* this is not so much developed. Quite a number of species, copying the most diverse kinds of *Pyrrhopyginae*, are found in Tropical America.

T. plutia *Hew.* (165 g) is a variegated species: on the black ground with a red base of the wings *plutia*. and a red thorax, a large discal vitreous spot of the forewing, a bluish longitudinal stripe below it, and a light blue submarginal band of the hindwing. Amazon District.

T. herrichi *H.-Schäff.* (165 f) is very similar, the red colour of a more yellowish tinge, besides there *herrichi*. are near the apex of the forewing 4 small vitreous spots, the blue rays are almost dying away. Patria unknown.

- erebus.* **T. erebus** Plötz (165 g). Here the vitreous spots and blue colour are entirely absent, so that it becomes very similar to *Mim. aspilos* (164 b). Described from Bahia.
- praecia.* **T. praecia** Hew. (165 g) greatly resembles *herrichi*, but the red colour turns here ochreous-yellow and is more extensive, assuming on the hindwing more the shape of an antemedian band and of a proximal-marginal ray, the light blue colour is more extensive, particularly on the hindwing, and on the forewing we notice bluish marginal lunae towards the proximal angle; besides there is a small, oblong hyaline spot between apical and discal hyaline spots. Brazil.
- corytas.* **T. corytas** Cr. (= *pyramus* Cr.) (165 g) has on the forewing 3 oblique, narrow hyaline bands and a reddish-yellow basal area, whilst on the hindwing the whole disc is reddish-yellow. Found from Surinam to Colombia.
- gaudialis.* **T. gaudialis** Hew. (161 a, as *dubius*) differs little from *corytas*. The ground-colour is a beautiful pure bluish-black, the basal areas of the fore- and hindwings are more red than yellow, and there appear blue submarginal diffuse patches, being still more prominent on the jet-black under surface. This beautiful species originates from the Chiriqui.
- bivittatus.* **T. bivittatus** Mab. & Boull. has, like *plutia*, a single tripartite hyaline band in the middle of the disc on the forewing; below it, between it and the border, 2 blue spots. The hindwing shows a double blue antemarginal band. Collar, thorax and abdominal base quite black, abdomen banded light blue; head black, palpi ashy-grey. From the Amazon.
- rufibasis.* **T. rufibasis** Mab. & Boull. (172 a). Forewing quite black with an oval, twice crossed, vitreous spot in the middle of the disc, the base of the wing with brown hair; hindwing with a light blue, straight antemarginal band flowing together with a brown discal band mixed with light blue before the inner-marginal area. Beneath the vitreous spot of the forewing is extended to the costa by a bluish continuation. The hindwing has 2 rather parallel, antemedian and postmedian bands; the whole rest of both wings beneath is black. French Guiana.
- perissographus.* **T. perissographus** Mab. (165 g) is on the forewing marked exactly like *corytas* (165 g), but the reddish-yellow colour is here blue, and the hindwing exhibits blue bands at the proximal margin, in the middle and before the border, converging towards the anal angle. From Panama.
- papias.* **T. papias** Hew. (165 g) is smaller, otherwise very similar to the preceding the vitreous spots of the forewings are much smaller, the blue colour somewhat more extensive, the blue basal area of the forewing parted by a black transverse band, and on the hindwing the black space between the median band and antemarginal band forks in the shape of a Y towards the costal margin, so that a blue, triangular costal-marginal spot is cut off. Brazil.

3. Genus: **Hypocryptothrix** Wts.

Allied to the preceding genus but in the habitus similar to certain *Yanguna*-species. The cell of the forewing is a little shorter, the two lower discocellulars about of the same length. The ♂ shows on the forewing beneath a hair-tuft at the base of the submedian. Only 1 species:

- teutas.* **H. teutas** Hew. looks like *Y. hadora* (164 c); it has a black body with a scarlet neck. The black forewing is lustrous green with a large, triangular, discal vitreous spot, the hindwing with white fringes. Described from the Amazon.

4. Genus: **Polythrix** Wts.

The separation from *Eudamus* is probably scarcely justified, for the sole difference consists of a secondary sexual mark in the ♂ exhibiting, like in the preceding genus, at the base of the submedian on the forewing beneath, a hair-tuft being covered by the strongly convex costal-margin of the hindwing. Only 1 species:

- metalles-cens.* **P. metallescens** Mab. (166 c) somewhat resembles the *Eudamus*-species of the *cholus*-group (161 c); above brown, tinted rusty-yellow, with 3 discal vitreous spots, placed almost like in *metophis* (160 d), and 3 small apical spots; the bases of both wings strongly haired metallic green, also beneath with a green reflection, on the hindwing with a white antemarginal band. Brazil (Manaos) and Panama (?).

5. Genus: **Eudamus** Swm.

The species of this well-known genus, mostly having long tails, show in the male a costal fold, except *curycles* and *orion*. The antennal club is bent round like a hook close behind the thickest part. The cell of the

forewing is very long, the transverse vein oblique, rectilinear; the middle radial rising nearer to the lower one, the lower median vein near the base, the upper one twice as far away from the latter as from the lower radial. On the hindwing the middle radial is absent, the submedian vein terminates into the more or less long tail. A great number of partly very similar species is distributed in Tropical America. About 80 forms are described; the animals are throughout dark brown, mostly with an oblique row of discal hyaline spots in the forewing. They very actively suck from flowers of all kinds and are, as a rule, not timid. Their flight, however, is very rapid. In sitting on a blossom, they always keep their wings half opened. Many are rather common.

E. dorantes *Stoll* (= *amisus* *Hew.*, *protillus* *H.-Schöff.*, *rautenbergi* *Skinn.*, *kefersteini* *Plötz*) (160 a). *dorantes*. A rather variable species, above olive-grey with a more or less brown tinge, in the disk with 5 square, yellowish hyaline spots, the 4 proximal ones of which extend in a line from the middle of the costal margin to the proximal angle and occasionally form almost a band; near the apex there are besides 3 minute hyaline dots, mostly a fourth at some distance below them. The under surface is light greyish-brown, on the hindwing often with violet or bluish-grey tints, 2 dark costal-marginal spots, 2 broader, undulate, antemedian and postmedian transverse bands and one narrower, submarginal band. — In the form **velinus** *Plötz* (160 a) from Bahia, which *velinus*. is not well reproduced by the figure, the hindwings beneath are of a darker violettish-grey with much narrower, distinct transverse lines, the distal spot of the costal margin being absent, the submarginal band terminating dark as far as into the border. Very widely distributed from Texas, Arizona, California, and Mexico to Venezuela; everywhere very common.

E. galbula *Plötz* (160 b) is a very similar species with narrower, more stretched wings; the middle *galbula*. discal macular band is placed more steeply, the 5th spot is more remote from it, the fringes are more profusely speckled light and dark. On the under surface the inner-marginal part of the forewing is almost white, the bands of the hindwings are less dentate, the whole surface not so indeterminate, the border darkened in uniform width. From Brazil.

E. santiago *Luc.* (= *cariosa* *H.-Schöff.*) (161 a). Above darker blackish-brown with much smaller, *santiago*. otherwise similar hyaline spots. The under surface is likewise much darker, particularly in the basal area almost purple-black, the transverse bands are more dentate and extend to the costal margin, the proximal one being united with the distal spot at the costal margin. — **retractus** *Plötz* from Venezuela, St. Vincent and Grenada, *retractus*. is presumably of the same species, of a more compact shape, with a shorter tail, and above the discal spots have almost disappeared. The typical form flies in Cuba. — **larius** *Plötz* (= *corydon* *Btlr.*) is said to differ *larius*. from typical *santiago* by its broader wings, the row of vitreous spots being more complete.

E. galapagensis *Williams* is quite similar to *santiago* (161 a), but not quite so dark, and the spots are *galapagen-* arranged the same, but mostly larger. Beneath the violet spot in *santiago* is here of a lilac tint; the tails of the *sis*. hindwings are shorter (only 3 mm). Chatham Island, Galapagos; common, from January to April and again in August; fond of resting in the shade of craggy rocks.

E. cenis *H.-Schöff.* (160 a) is a species with shorter tails and a rounder costal angle of the hindwings; *cenis*. above similar to *galbula* (160 b), but the hyaline macular band is narrower, and on the hindwing there appears a darker median band. Beneath likewise similar, but the inner-marginal area of the forewing is not so light. Colombia. — **athesis** *Hew.* has grey fringes and a lighter under surface. *athesis*.

E. procerus *Plötz* (160 b). In this species the hyaline spots of the disc, which are here of a pure white, *procerus*. not yellowish, are placed together in to a broad oblique band, also the apical spots rather large, the fringes of the hindwing yellowish, not speckled. Beneath similar as *galbula* (160 b), the proximal median band confined to a dark cell-spot, both the costal-marginal spots are entirely absent, the distal band is interrupted in the lower half. From Peru.

E. athletes *Fldr.* is allied to *proteus* (160 f), but the wings are broader, hindwings in the anal area *athletes*. less elongate, the tails more slender and of a smaller shape. Basal part of the wings above with olive hair, forewing with 4 discal spots arranged in one line, and with another distal one; 3 small ones near the apex. Hindwings beneath brown, densely dusted violettish-grey; double subcostal spots, 2 shortened bands blackish-brown, dusted brown with grey margins and an obsolete, undulate submarginal stripe. Colombia and Brazil.

E. proteus *L.* (= *domingo* *Scudd.*) (160 b) is a well-known, common species, easily recognized by *proteus*. the green hairing of the basal part above particularly in the hindwing. The forewing exhibits a yellowish discal oblique band which is almost extinct in the form **proteoides** *Plötz* from Florida and the Antilles. Beneath the *proteoides*. hindwings exhibit, on the dark brown ground, 2 thick dark transverse bands and mostly an isolated costal-marginal spot between both. — **esmeraldus** *Btlr.* is presumably only a large species with a brighter metallic *esmeraldus*. green reflection on its body and base of the wings from more southern habitats, in which the distal band of the hindwing beneath is parted by white. — *proteus* is found in North America in the Atlantic States and from Mexico almost through the whole of South America. The larva is green, posteriorly reddish with a red-brown head and light lateral stripes. It lives between two leaves of *Glycinia* being joined together and on other *Papilionaceae*.

- aelius*. **E. aelius** Plötz (160 b, c) is above similarly marked, but without any green and with a white ante-marginal line before the white fringes of the hindwing. Under surface of the hindwings almost like in *eurycles* (160 e). Described from Pará.
- clevas*. **E. clevas** Mab. greatly resembles *aelius* above, the hyaline spots of the discal band are not scalariformly arranged, but form a rectilinearly defined oblique band, of a white, not yellowish colour. A white ante-marginal line in front of the fringes is noticed here only beneath; otherwise the hindwings are beneath very much like those of the preceding species. Brazil.
- talthybius*. **E. talthybius** Mab. likewise belongs here; 50 mm, thus very large. Base of wings like in *proteus* (160 b), of a metallic green like the body. The discal hyaline band of the forewing broad, coherent, tapering towards the proximal angle, slightly yellowish. Hindwing with a short, broad tail and dirty-white fringes, beneath rusty-brown with 2 not very distinct, black transverse bands like in the preceding. Described from Brazil.
- concinus*. **E. concinns** Mab. Above blackish-brown with speckled whitish fringes and yellowish hyaline discal spots. Beneath the apex of the forewing is of a light grey. Hindwing at the base blackish-grey with a darker transverse band, behind it a whitish band-like space, parted by a darker colour; in the lilac-grey distal area a curved, black spot. Expanse of wings: 47 mm. Brazil.
- alcaeus*. **E. alcaeus** Hew. (= *montezuma* Scudd.) (160 c) in the scheme of markings above resembles *proteus* (160 b), but it has no green, but ochreous-brown hairing on the body and bases of the wings. Beneath easily recognizable by the extensive white area in the discal and lower half of the hindwing, and by the torn black marking. Arizona, Mexico, Costa Rica, Ecuador.
- aminias*. **E. aminias** Hew. (= *pithys* Schs.) (160 e) is allied to *alcaeus*. Above the discal macular band is of a yellower tone, the bases of the wings, however, of a darker ochreous-brown. Beneath the hindwing is reddish-grey with torn black spots without the white marginal area. Colombia, Brazil.
- tarchon*. **E. tarchon** Hbn. (= *longicauda* Sepp) (172 a) is very closely allied to the following, but the spots of the forewings are whiter, and on the hindwing beneath the white band is more concave, its lower part split up in 2 parts either by a blackish ray or by 2 spots being above pointed. — MABILLE considers it to be only a form of *catillus*. From Brazil.
- catillus*. **E. catillus** Cr. (= *ixion* Plötz) 160 a). Above little different from *dorantes* (160 a), but the forewings project somewhat angularly below the apex. Under surface of the hindwing very variegated: particularly prominent is an antemedian band bent almost rectangularly on the upper median vein, behind it a lighter, lilac-grey space into which a brown dentiform spot projects from the direction of the dark proximal margin. Widely distributed in South America.
- zilpa*. **E. zilpa** Btlr. (160 d). Here the angle below the apex of the hindwing is still more pronounced, the hindwings beneath still more variegated: at the costal margin brightened up by lilac, a large inner-marginal spot almost white, the macular marking in contrast with it of a deep brownish-red; also behind the small spots in the apex of the forewing beneath there is a deep dark triangular spot. From Mexico through the whole of Central America, to the north as far as Arizona.
- cinereus*. **E. cinereus** Mab. is brown with an ashy-grey haired basal area. In the forewing the 3 subapical punctiform spots are arranged in an oblique row, 4 white hyaline spots form a discal band and a 5th is situate apart of them. Apex of forewing very much extended. Beneath the apex shows a lilac tinge. The hindwings are beneath brown with an ashy-grey margin and a large white ray from the costa, expanded to a triangle as far as the inner-marginal fold, where it is filled up by a diffuse ashy-grey spot. The hairing of the brown body is grey and shows a somewhat green reflection; palpi white. Brazil.
- myrto*. **E. myrto** Mab. is allied to *catillus* (160 a), but with much larger and yellower discal spots above, and the small apical spots are not arranged in a row, but the third is removed towards the margin. The hindwing is concavely indented below the costal angle, the undulate fringes are white. Forewings beneath of a light red-brown; hindwings very much like in *catillus*, at the margin blackish with a fine silvery line in front of the fringes, the macular markings violettish-black, the subbasal, angled band broken up into 4 spots: 2 round ones near the costal margin, encircled by whitish, then a large one in the middle, enclosing a small silvery spot and in the whitish anal area another tooth-like spot. Hayti.
- stylites*. **E. stylites** H.-Schäff. (160 c) is a smaller species, distinguished by an almost white inner-marginal area of the forewings beneath; the pale lilac-grey hindwings speckled with brown exhibit 2 brown transverse bands, the proximal one being broad, slightly curved, bordered dark, the distal one almost streak-shaped. Colombia, Brazil.
- callias*. **E. callias** Mab. somewhat resembles *procerus* (160 b), above marked just the same, towards the base with a green lustre, spots purely white diaphanous. Forewings beneath reddish-brown, the hyaline spots margined darker, hindwings light reddish-grey with 2 minute dark spots at the costal margin like in *dorantes* (160 a), but at a much greater distance from each other; in the cell a round black spot and a short black band behind

it. Body beneath haired greenish-yellow. Porto Cabello.

E. callicina Schs. is very closely allied to the preceding and is marked the same, above brown, towards *callicina*. the base and at the proximal margin of the hindwing haired olive-yellow; hindwings with traces of 2 darker transverse bands; fringes white. Beneath the forewings are brown with a lighter proximal margin, the hindwings brown, tinted violettish, a proximal, dark, narrow band broken up into spots, and a slightly curved, distal, short band. Expanse of wings: 46 mm. Honduras.

E. juanita Schs. seems to be closely allied to *stylites* (160 c), distinguished by lighter, dark speckled *juanita*. fringes; the vitreous spots are arranged like there, whitish. Hindwings haired olive. Under surface also like in *stylites*, but at the costal margin near the base of the hindwing there is yet a brown spot, and the distal band is more undulate. Expanse of wings: 38 mm. Rio de Janeiro.

E. platowi Plötz (160 c) is larger than *stylites*, above similarly marked, but with larger purely white *platowi*. hyaline spots, of a deeper black ground-colour and extensive olive-green hairing on the body and bases of the wings. Fringes of the hindwings whitish, speckled dark. Beneath easily discernible by the large, brownish-black discal area being distally irregularly defined, containing a whitish middle luna and being bordered towards the proximal angle by a whitish, short band. Patria unknown. Perhaps an aberration from *proteus*.

E. megaeles Mab. is very closely allied to *platowi* and exhibits the same hyaline spots. DRUCE takes *megaeles*. be it to a form of *esmeraldus* with confluent spots on the hindwings beneath; forewings below the apex sharply angled, fringes of the hindwings unicolorously dirty grey, hindwings blackish as far as the costal margin with a light middle luna and the marginal area tinged light yellowish-green and lilac. Brazil.

E. metophis Latr. (160 d) is above not unlike *proteus* (160 b), but with a shorter, broad tail and mostly *metophis*. only 2 or 3 discal hyaline spots. Hindwings extensively haired olive-green. Beneath brown with a light proximal margin of the forewing; hindwings dark brown with white fringes and a yellowish-white, narrow band parallel to the border, touching neither the costal nor proximal margin. Distributed in South America.

E. jethyra Btlr. (160 e) is not to be mistaken for any other species owing to the extensive ochreous colour- *jethyra*. ring above and the large ochreous-yellow discal spots; also the fringes of the hindwings are yellow, speckled darker. On the under surface allied to *zilpa*. From Peru.

E. harpagus Fldr. (160 e) is probably the largest species, on the body and base of the hindwings *harpagus*. haired slate-blue. Under surface of hindwings of a deep blackish-brown with a violettish-grey distal area parted by a band of the groundcolour with 3 proximally projecting teeth. Colombia.

E. albofasciatus Hew. (160 d). Above like *zilpa*, but the angle below the apex of the forewing does not *albofascia-* project so much; beneath unmistakable by the broad, silvery white transverse band. In Central America wide- *tus*. spread and mostly common; to the north as far as Texas and Arizona.

E. simplicius Stoll (= *pilatus* Plötz, *proene* Plötz) (160 e) is the most common and most insignificant *simplicius*. species, above unicolorously blackish-brown, without any spots, beneath likewise brown, on the forewing with 2 light costal-marginal spots, and on the hindwing with 2 partly interrupted blackish diffuse bands and an isolated spot at the costal margin near the base. — **eurycles** Latr. (= *zagorus* Plötz, *zalanthus* Plötz, *sumich-* *eurycles*. *rasti* Scdl.) (160 e) is certainly only a subform differing by the presence of a narrow, yellowish-white oblique band and 3 or 4 small apical streak-spots. There are numerous transitions. From Texas through the whole of Central and South America. — **ab. latipennis** Mab. is larger, the wings broad and lustrous. The median *latipennis*. band composed of 5 spots, broader, before the apex 4 or 5 punctiform spots in one line; hindwing beneath at the base with 2 very small spots and the fringes almost white; the tail is broad and very long; the ♂ without a costal fold. Colombia and Guiana.

E. gracilicanda Plötz (161 e, f) is like *simplicius* above and beneath brownish-grey, without any hyaline *gracili-* spots, with a finer, longer tail. Beneath the proximal margin of the forewing is lighter, on the hindwing the *canda*. costal-marginal spots are absent, the 2 transverse bands are passing through to the costal margin, the proximal margin darkened. Patria unknown.

E. carmelita H.-Schäff. (161 b) greatly resembles *eurycles*, above different by a somewhat broader *carmelita*. white band and a small spot outside in the middle of it in the angle between the median and radial vein. Beneath the hindwing exhibits an antemarginal violettish-grey band as broad as the similarly coloured fringes. From Brazil. — **trebia** Mschlr. (161 b, c) is quite similar, but of a blacker ground-colour, the median band broader, *trebia*. more coherent, the apical and subapical dots, 6 in number, form a curved line. Hindwing with a white band extending from the costal angle to the tail-appendage; hardly separable from *carmelita*. — **nigricauda** G. & S. *nigricauda*. differs from typical *carmelita* by the hyaline band of the forewing being straight, coherent and broader, from *trebia* by 5 subapical dots arranged in a straight line running parallel to the median band. Beneath the white band of the hindwing is broader than above.

- chalco.* **E. chalco** Hbn. (= *agesilaus* Swns.) (160 f) is a large, beautiful species, above on the body and bases of the wings with a bluish olive-green reflection, forewings marked like *carmelita* (161 b), hindwings with a broad, white distal area and tail, the former extending only beneath to the costal margin. South America.
- dominicus.* **E. dominicus** Plötz (= *albimargo* Mab.) (160 f) is smaller, with a much shorter and finer tail and a very narrow white marginal area of the hindwing, about the width of the fringes, above not with green, but only with some slate-coloured hair. South America.
- brachius.* **E. brachius** Hbn. (160 f). Above like the preceding with a short broad tail, but with a very broad inner-angular spot, almost extending to the middle of the wing; beneath on the hindwing there appear in the white marginal area 4 or 5 blackish-brown spots before the fringes, increasing in size towards the costa. —
- doryssus.* The form **doryssus** Swns. (= *nivosus* Plötz, *orion* Drc. nec F.) (161 b) is the same, though with a somewhat narrower white area of the hindwing not extending to the middle of the wing, particularly above. —
- chales.* **chales** G. & S. (160 f) is presumably likewise not a separate species, but like *simplicius* from *eurycles*, it differs by the absence of the white oblique band on the forewing; the white distal part is not much broader than in *doryssus*. From Mexico to Brazil.
- loxo.* **E. loxo** Mab. is larger than the preceding, distinguished by the fringes of the forewing being white towards the inner-angle, while in the other species they are blackish-brown. The marginal area of the hindwing is particularly beneath very broad white, towards the costa tinged blackish-brown, the black colour being continued before the margin for some distance as far as into the very broad white tail. Santa Catharina.
- albicuspis.* **E. albicuspis** H.-Schäff. (= *leucites* Mab.) (168 b) closely approaches *brachius* and is above to be separated by a tooth of the blackish-brown ground-colour on the submedian fold projecting far towards the margin into the very broad white anal part, whereas on the submedian vein a white tooth projects far towards the base. Beneath the white colour is almost as broad as above, only towards the costal margin somewhat narrower, towards the costal angle on the border some few blackish-brown diffuse spots. Colombia, Brazil.
- herophilus.* **E. herophilus** Plötz (= *virescens* Mab.) (161 b) is above the most similar to *albimargo* by the extent of the white colour, but towards the base on both wings and on the body strongly haired green. Beneath the hindwing is marked with an indistinct black, postmedian transverse band and a black costal-marginal spot before it. From Surinam to Rio de Janeiro.
- orion.* **E. orion** F. (161 b) is a magnificent species, above somewhat like *brachius* (160 f), but with longer tails, and a much broader white discal band of hyaline spots on the forewing. Beneath very much like the following *undulatus*, except the broad white distal area slightly tinged reddish-brown, on the hindwing. Central America.
- undulatus.* **E. undulatus** (= *niciasus* Plötz) (160 a, b). Above brown with an oblique band of hyaline spots on the forewing, being slightly tinged yellowish. Beneath reddish-brown, watered darker, with 2 partly interrupted, irregularly dentate, slate-coloured to blackish-grey transverse bands and black clouding at the base of the hindwing. Mexico to Brazil.
- elongatus.* **E. elongatus** Plötz (160 d) most closely approximates *undulatus*, differs, however, by but one distal transverse band on the hindwing beneath. Brazil.
- evenus.* **E. evenus** Mén. (161 c) from the affinity of *albimargo*. Very much distinguished by the very broad, yellowish-white discal band on the forewing and the almost equally broad, yellowish-white border of the hindwing, into which small spots of the ground-colour project on the ends of the veins. Beneath marked like *simplicius-eurycles* except the yellowish-white border. Described from Brazil.
- eudoxus.* **E. eudoxus** Cr. (161 c) is like the following species marked by an equally broad, yellowish-white antemarginal band on the hindwing beneath, running about parallel with the border, forming, however, a hook towards the proximal margin at the tail. Above the forewing exhibits a rather broad, white discal band reaching neither the costal margin nor the proximal angle. Body and bases of the wings with green hair. Guiana.
- leucogramma.* **E. leucogramma** Mab. differs from *eudoxus* by different hyaline spots of the forewings, which are about arranged as in *proteus* (160 b) with which the species is at any rate best to be compared above. Beneath the red-brown hindwings show a slightly curved antemarginal band terminating at the tail and not turning round towards the proximal margin. Porto Cabella.
- cholus.* **E. cholus** Plötz (= *glaphyrus* Mab., *leucodesma* Plötz, *albistria* Plötz) (161 c) is above and beneath quite similar, but the tail is much shorter, and on the hindwing beneath the white band is much narrower, not sharply defined as in the preceding. Brazil.
- ganna.* **E. ganna** Mschr. (161 c) is a much smaller species with a considerably finer, neater tail, otherwise very closely allied to *cholus*; the white band of the hindwing is on both sides sharply defined and particularly towards the margin of a darker tinge. Venezuela.

E. piliger *Mab.* Similar to *ganna* (161 c), but larger, the middle of the wings somewhat reddish, *piliger*. Forewing with yellowish spots: 3 near the apex, 3 in the disc, 1 of which is in the cell. Tail of the hindwing broad and short, fringes of the forewings grey, of the hindwings white as far as the tail; base of hindwing metallic green. Hindwing beneath of a pure brown, a straight white band, crossed by the veins, extending from veins 2 to 7. A grey spot beginning in the 8th interspace. 39 mm. In the Coll. STAUDINGER (Berlin). From Itaituba.

E. octomaculata *Sepp* (= *calenus* *Mab.*) (161 d as *maculata*). This species initiates a group of forms, *octomaculata*, in which the discal spots are not of the shape of a band, but exhibit more a condensed group of discal spots. The colouring above is a pure olive-brown with an indistinct, darker brown antemarginal shade on all the 4 wings, being of a lighter grey tinge beneath, particularly on the hindwings. The tail is here short triangular. From Mexico through Central America to the Amazon. — The bluish-white larva with a yellow head lives on *Pterocarpus indicus* and changes into a reddish-yellow pupa on a leaf having been drawn together in a boat-like shape by some few threads.

E. auginus (161 d) is smaller on an average, on the body and bases of the wings haired green; above *auginus*, the darker nebulous bands are scarcely visible, beneath on the hindwing towards the proximal angle with a whitish spot before them. Guiana, Colombia, Brazil.

E. auginulus *G. & S.* (161 d) is still smaller, with shorter tails terminating more pointedly; whilst in *auginulus*, *auginus* there are only 3 hyaline spots in the disc, the present species has one more above them at the costal margin; the forewing beneath is almost whitish-yellow at the proximal margin, above on the light, olive-yellow hindwing there are 2 distinct transverse bands visible. Mexico.

E. flammula *H.-Schäff.* (= *lindora* *Btlr.*) (161 d) is larger than *auginus* with much longer tails, *flammula*, the bases of the wings are not haired green, but somewhat olive-yellow. On the under surface the white spot at the proximal angle is larger and lighter. Brazil. Perhaps only a form of *auginus*.

E. alciphron *G. & S.* (161 d) differs from *auginulus* by its larger size, longer and broader tails, much *alciphron*, larger hyaline spots, and like *octomaculata* dark transverse bands on the upper surface of all the wings. On the hindwing beneath with a white transverse band, distally parted by black. Mexico.

E. asine *Hew.* (= *caenus* *H.-Schäff.*) (161 d) is a larger species, above dull olive-brown, with the *asine*, usual hyaline spots, more or less distinct nebulous bands across the wings, on the forewing yet with a small round spot or small ring-spot towards the base near the proximal margin. Beneath the forewings are lighter, the hindwings darker dusty olive-brown, the hindwings with 2 irregularly spotted, darker nebulous bands. Mexico to Nicaragua.

E. ceculus *H.-Schäff.* (161 d) is smaller than *auginus*, with shorter, more pointed tails, without *ceculus*, any green; forewing without any dark marking, only the hindwing exhibits a darker cell-streak and a blurred antemarginal band. Beneath like *auginus*, though without the light inner-angular spot with a darker cell-spot. Rio de Janeiro.

E. obscurus *Hew.* The description runs: „Blackish-brown; forewing with 2 apical, transparent *obscurus*, dots. Hindwing with a short and broad tail. Beneath deep brown; forewing at the apex lighter and at the border with a brown nebulous spot near the apex. Hindwing lighter, traversed by 2 macular bands being darker than the ground of the wing.“ No patria mentioned, and MABILLE and BOULLET assume it to be a *simplicius*, but that by the dark spot below the apex the species deviates from this group.

E. hirtius *Btlr.* (161 e) is the largest species of this group, above like *asine*, but with much more extensive *hirtius*, hyaline spots, which are here particularly proximally bordered with a dark brown, whereby they are distinctly prominent. The hindwings beneath are only very feebly marked. From Venezuela.

E. decurtatus *H.-Schäff.* (161 e) is very similar but smaller, with comparatively longer hindwings, *decurtatus*, but shorter tails; the hyaline spots of the forewing are reduced, not so yellowish as in the preceding, the under surface is much more intensely marked with 2 dark transverse bands flowing together at the costal margin. Colombia, Brazil.

E. decussatus *Mén.* (161 e) is presumably to be considered as an insular form of the preceding from *decussatus*, which it differs little. On the forewing the advanced hyaline spot of the discal row between the median and radial vein is absent, instead of which the lowest apical spot is removed towards the margin. Beneath the dark transverse bands run more rectilinearly. Hayti.

E. ridens *Hew.* (= *coronus* *Plötz*) (167 b) initiates a group of species with very short tails, of which *ridens*, *ridens* is the largest and finest. Above chocolate-brown with very extensive hyaline spots; the hindwing exhibits a short, white discal band and at the proximal margin a dense cover of white hair. Beneath on the hindwing,

behind the cell, a broad white band being in the distal half shortly parted by black. Panama to Brazil. — *cachinnans*. ***cachinnans* G. & S.** (161 e) is presumably only a subform of it, the white band on the hindwing beneath being broader, and the body and base of wings being suffused with green. Likewise described from Panama.

millas. ***E. millas* G. & S.** (161 e) from Mexico differs by the hindwings being lighter beneath, with torn darker macular bands; the white band is only visible at the proximal angle as a diffuse spot.

crison. ***E. crison* G. & S.** (161 e) greatly resembles *cachinnans* beneath, but the band of the hindwing is above dull blue, parted at the greenish costal margin, whereby it has the shape of a Y. Central America.

hyster. ***E. hyster* Dyar** (166 d) is likewise similar, smaller, above darker with reduced discal spots. Beneath the hindwings are at the base of a dark blackish-brown, in the distal area light lilac grey with a bluish-grey dusting; the broad white transverse band shows towards the costal margin 2 dark spots near its distal edge. Sierra de Guerrero (Mexico).

biolleyi. ***E. biolleyi* Mab.** Forewing above with a short white band composed of 4 dissimilar spots, hindwing beneath without a white discal band, but with a spatulate, prolonged lobe with white edges and fringes.

To this genus belong yet a number of Hesperid forms having for some reason or other been described as *Thymeles*, *Goniurus* etc., and presumably do not all deserve denominations. Thus „*Thymele*“ ***guatemalaina*** *guatemalaina* is allied to *proteus*, though the spots are not so distinctly separated; beneath the palpi are reddish-yellow, thorax brown, abdomen ash-grey. Forewing light brown, at the proximal margin still lighter, spots like above, hindwings dark chestnut-brown with a narrow, flesh-coloured marginal band, beginning on the costa near the apex and extending to the lower median rib. All the fringes a little lighter than the ground-colour. Expanse 49 mm, the tails 6 mm. From Cayabon in Guatemala.

borja. „*Thymele*“ ***borja* Ehrm.** The body above very dark brown. Both wings in the ground fawn-coloured, with a dark brown margin, the fringes a little darker than the ground-colour. The body beneath dark brown, the forewings lighter than above, with diaphanous spots like above, and two dark brown undulate lines on the band. Hindwings like the forewings, on the costa near the base a four-cornered spot, laterally to it two dark brown streaks on the band. The tails are 10½ mm long. Expanse of wings: 49 mm. — Borja, Bolivia.

thiemei. „*Thymele*“ ***thiemei* Ehrm.** seems to be allied to *Eud. eurycles* (160 e). Above dark brown, the tails almost blackish-brown. All the fringes light brown, at the tails black. Beneath light brown, forewing with a prominent band, in the apical area a large, dark brown, triangular spot; in the hindwing the markings are like in *T. eurycles* Latr. The tails are 18 mm long, the expanse of wings: 45½ mm. From Honduras.

terraccina. „*Thymele*“ ***terraccina* Ehrm.** ♀ above very dark brown, thorax, however, covered with long green scales. Forewing dark brown, in the basal area light greenish, at the distal end of the discal cell there is a large, V-shaped, transparent spot, above this spot on the costa there are two narrow, oblong spots of the same colour. Below the discoidal cell in the limbal area, there is an almost straight row of three diaphanous lunae, in the apical area a curved row of 6 transparent spots between the costa and the upper median rib. Hindwing dark brown, the basal area dusted green. Fringes of a pure white. Forewing beneath light chestnut-brown with transparent spots as above. Hindwing beneath very dark brown, at the apex ash-grey, between the median and the lower submedian some white dusting. Expanse of wings: 64 mm. — Remedios, Colombia (South America).

viterboana. „*Thymele*“ ***viterboana* Ehrm.** (sex?). Body above olive-brown. Forewing above in the ground chestnut-brown, in the basal area bluish-green, transparent spots like in *T. harpagus* Feld., but less distinct. Hindwings of a darker ground-colour than the forewings, costa lighter, median area of a nice olive-green. Under surface dark brown, forewings beneath lighter than above, in the distal marginal area, however, darker, the spots as above. Hindwing dark brown, basal and costal areas lighter, in the marginal area two lighter brown streaks. Tails 4½ mm, expanse of wings 55 mm. Socorro, Colombia (South America).

cleopatra. „*Goniurus*“ ***cleopatra* Ehrm.** from Venezuela (Suapure) only measures 39 mm, and is certainly allied to *Eud. orion* Cr. ♀ above dark brown, the costa from near the base to the hyaline stripe expanding across the cell is white, the stripe on the fascia and the spots in the subapical zone as in *G. triptolemus*, beginning from the cell the marginal area and the tails are white like the fringes. Hindwing dark brown, the dorsal area dusted white beginning from the median cell, the fringes of the apical and dorsal margins are dark brown. — Beneath the body is lighter than above, with faintly indicated two lateral bands on the venter, legs dark brown. Ground-colour of forewings much lighter than above, the dorsal area is white. In the hindwing the ground-colour is very

dark brown, the marginal band and the tails are of a pure white except 4 faint lunae in the apical area. Tails $1\frac{1}{2}$ mm long.

G. triptolemus *Ehrm.* ♀. Body above dark brown. Forewing above dark brown, on the fascia there is a transparent stripe composed of 4 dissimilar spots. In the median cell beyond this stripe there is a narrow, diaphanous spot right across the cell, in the subapical area a row of 4 very small transparent spots. Hindwings a little lighter than the forewings, the tails white. The apical fringes are white, above slightly mixed with brown. Fringes at the border and at the tails very long and of a pure white, the anal fringes shorter and brown. Under surface much lighter than above; ground-colour of forewings lighter than above, with the same markings as above, but the transparent stripe is more prominent. Ground-colour of hindwings like that of the forewings, on the fascia there are three brown stripes indicated; the border purely white, tails brown, with white fringes. Length of tails: $4\frac{1}{2}$ mm. Expanse of wings: 52 mm. Bagasas, Costa Rica.

6. Genus: **Plestia** *Mab.*

In its anatomical marks it corresponds with *Eudamus*, but the hindwing has no tail, but a deeply dentated distal margin and a somewhat prolonged, rounded anal lobe. The antennal club represents a uniformly curved spindle tapering gradually. Body and wings very hairy. 4 species:

P. staudingeri *Mab.* is above red-brown with yellow hyaline spots, being similarly arranged as in the following, but the hindwing shows two hyaline bands and is more dentate. Described from Guatemala.

P. dorus *Edw.* (172 c) from South Arizona and Mexico has a reddish-brown upper surface with 3 yellowish discal spots, 2 or 3 minute apical spots and an antimarginal band extending from the lower radial vein close to the proximal margin. The hindwing shows behind the cell a hyaline band, being distally somewhat concave. Beneath the proximal margin of the forewing is broad honey-coloured, the hindwing exhibits 3 dark brown transverse bands.

P. elwesi *G. & S.* (172 c). Here the distal macular band of the forewing contains two small spots more; beneath the hindwing is of a pure yellow, with a macular band above the base and 2 black median spots enclosing a white spot near the costa, and a series of black marginal dots. Very closely allied to *dorus*. Central America.

P. kikkawai *Weeks* from Venezuela is, according to the indistinct description, above dark brown, the forewing with 9 white spots, the largest of which is situated in the middle of the discal area, with darker margins. Costal margin and base of hindwing above white; in the middle of the wing a white spot with a small one attached to it, outside indistinct, small brown spots, and at the border a light brownish line. Beneath the hindwings are darker, with the white markings of the upper surface. A small species of an expanse of $30\frac{1}{2}$ mm, taken in January.

7. Genus: **Heteropia** *Mab.*

Large, robust animals with a moderately strong, gradually thickened antennal club being bent like a hook and ending into a fine point. The cell of the forewing is exactly two thirds of the length of the costal margin, the ♂ has no costal fold. The upper discocellular is very short, the two lower ones turned obliquely proximad, of the same length; the upper median vein rises near the cell-end, twice as distant from the lower radial vein as from the upper one. The hindwing are slightly angled on the inner-marginal vein. The posterior tibiae show 2 pair of spurs. The species occur in Central and South America.

H. imalena *Btlr.* (= *imitatrix* *Mab.*) (161 f upper surface, 171 d under surface) is above black, with a blue reflection and an oblique, white, discal hyaline band, in the angle between the radial and median vein with an isolated, longish spot and 2 or 3 minute apical spots; fringes speckled white and black. Under surface dark brownish-grey, marbled lighter, on the hindwing towards the margin lighter lilac-grey, with 4 incomplete spotted transverse bands. Costa Rica to Colombia.

H. bryaxis *Hew.* (161 f) is above marked the same, but like the following species above brownish-black, towards the base lighter ochreous-yellow. Beneath very much like *imalena*, the transverse bands of the forewings more distinctly prominent, towards the proximal margin of a deep velvety brownish-black, the lilac-grey distal area the lightest near the proximal angle. México to Guatemala.

H. cyda *G. & S.* (161 f) is very closely allied to *bryaxis*, but above much darker brown, almost without any ochreous brightening, and on the hindwing with an indicated darker discal and marginal band. Beneath the ground-colour of the hindwing is of a rather uniform lilac-grey, at the anal angle almost purely white. Mexico to Honduras.

H. melon *G. & S.* (161 f) likewise approximates *bryaxis*, being somewhat larger, above also ochreous-yellow towards the bases of the wings, with mostly larger discal macular bands. Beneath the colour of the

hindwings is much more variegated, towards the margin almost whitish-grey, the marginal darkening much less, the transverse bands more torn, particularly the distal one partly only in the shape of a dentate, fine, black line distally shaded by reddish-brown, near the proximal margin expanded to a thick black spot. — f. *arizonensis*. **arizonensis** *Skinn.* has a somewhat lighter ground between the bands of the hindwings, and the anal angle is of a whitish ash-grey. Arizona.

cyledis. **H. cyledis** *Dyar* (171 d) is above almost like the preceding. Beneath the hindwing shows a large white area in the middle of the distal margin, which is pierced from above and below by a brownish, transverse irroration; the transverse bands are of a deep black, torn, the extreme band at the white area deeply concave proximally. Marginal area only very narrowly darkened by brownish. Hitherto only known from the state of Puebla (Mexico).

8. Genus: **Goniurus** *Hbn.*

This genus is distinguished by a somewhat more slender antennal club turned round in the middle like a hook; the 2nd palpal joint is densely scaled, the 3rd short, obtuse conical, extending straight forward. The cell of the forewing is longer by two thirds than the costal margin; the ♂ exhibits a costal fold. The transverse vein runs very obliquely, its middle part being longest; the lower median vein rises near the base, the upper one just before the cell-end. The hindwing with a distinct tooth or short tail at the inner-marginal vein; transverse vein and middle radial are very feeble, the doubly spurred posterior tibiae with fringes.

caelus. **G. caelus** *Cr.* (= *aurunce Hew.*, *hypozoneus Ploetz*, *gideon Ploetz*) (166 c). Above blackish-brown, on the body and bases of the wings metallic green with an ochreous-yellow, hyaline discal oblique band, a minute spot behind it and 2 or 3 minute apical spots. The under surface is more brownish, the hindwing exhibits a broad, silvery white discal band. Central and South America, beginning from Mexico.

talus. **G. talus** *Cr.* (= *lucidator Sepp*, *ausonius Latr.*) (166 d) is very similar, the hindwings, however, with shorter tails and beneath without a white band, but only a darker, blurred transverse band, bordered by two small lighter spots towards the proximal angle. From Mexico to South America.

passalus. **G. passalus** *H.-Schäff.* is the most closely allied to *talus* (166 d); above black, body, base of forewing and almost the whole hindwings of a deep green reflection, with a nearly equally broad white hyaline band without any apical spots. Hindwing beneath almost unicolorously green, only at the border narrowly greyish-brown. Brazil. Perhaps to be placed to *Thymeles* near *eudemus*.

9. Genus: **Epargyreus** *Hbn.*

Large, imposing animals with a very much extended apex of the forewing and a slight angle below it. Antennal club strong; 2nd palpal joint appressed, 3rd very short. Venation of forewings as in *Goniurus*; hindwing with a strong lobe on the inner-marginal vein. Nearly all the species have on the hindwing beneath silvery or mother-of-pearl white spots and in the hindwing yellow hyaline spots. The larvae, as far as they are known, are slender, mostly greenish, with transverse irrorations, the first ring being thin like a neck, whereby the mostly red or yellow head is strongly defined. They live on tree-like Papilionaceae between two leaves that are drawn together by means of strong threads. The change into a slender pupa takes place on the soil between leaves.

The pupae of *E. tityrus* have been exported in numbers to Europe in the last years, but they easily die on the way there. The butterflies are very common in tropical America, and one species goes to the north as far as the northern parts of the United States, where it is considered to be noxious by some authors (HARRISON, PACKARD). They fly very swiftly with an almost whizzing flight, and with their wings half open they cling to all kinds of blossoms and may be easily taken while sucking them, whereas the ♂♂ on their coupling flight are very timid.

tityrus. **E. tityrus** *F.* (= *clarus Cr.*) (166 e) is above brown with a broad ochreous-yellow discal hyaline band, a small isolated spot outwards of it, and 2 to 4 small apical spots. Beneath the same, on the hindwing with a very broad, silvery white band, being irregularly dentately bordered. From the United States to the south as far as Panama, in more southern districts in 2 or 3 generations. — The greenish larva, with a red-brown head, lives between two leaves drawn together with few strong threads, of Glyciniae (*Wistaria*), Robiniae and other Papilionaceae, and pupates on the ground between leaves.

exadeus. **E. exadeus** *Cr.* (= *socus Hbn.*, *clavicornis H.-Schäff.*) (166 e) is much larger, with longer wings and smaller, lighter hyaline spots. On the hindwing beneath, the silvery spot is more or less reduced, mostly to one larger, roundish spot in the proximal half and one or two above it; distally there is a fine, undulate, partly silvery line, and the distal part is of a light violettish grey, finely dusted darker. Widely distributed from Mexico almost through the whole of South America, and common. — The larva is green, with a fine, darker transverse

striation and a red 1st ring and feet and a dark brown head spotted red. It lives on Papilionaceae.

E. pseudexadeus Dbl. & Hew. (166 e) has a very much broader ochreous-yellow discal hyaline band, *pseudexadeus*, and on the hindwing beneath much more silvery markings, being otherwise very much like the preceding. South America.

E. maysii Luc. (= *egaeus* H.-Schöff.) (166 e, f) from Cuba is very closely allied to the preceding *maysii*, beneath, but on the forewings much darker, since the yellow discal spots above and beneath are absent except 2 small costal-marginal spots.

E. antaeus Hew. (= *euthymides* Plötz) (166 f) is most similar to the *tityrus* above, but it has quite *antaeus*, unspeckled fringes; beneath the hindwings are lighter, more violettish-grey, and the silvery band is more equally broad and more regularly defined. Brazil.

E. boisduvalii Ehrm. has an expanse of 52 mm. It is allied to *antaeus* Hew. Above brown, in the middle *boisduvalii*, of the costa a small orange spot, below it a truncate, semi-transparent yellow spot, in the limbal area 3 small round similar spots, below in the marginal area a distinct orange spot. On the hindwing 2 small yellow spots in the middle cell of the distal area; all the fringes flesh-coloured. Beneath similar, forewings lighter, hindwings of a deep chocolate-brown, above the disc 2 silvery-white streaks, the orange spots in the distal area like above. Suapure (Venezuela).

E. asander Hew. (166 f) is above much darker, towards the base not so ochreous-yellow as the *asander*, preceding, with a narrower discal band; beneath on the hindwing the silvery white band is narrower, duller, only proximally sharply defined, distally more faded, the distal half light lilac-grey. — In the form **panthius** *panthius*, H.-Schöff. (= *arsaces* Mab.) (166 f) the silvery-white colour of the band is almost entirely absent. — f. **scheba** *scheba*, Plötz (166 f, g) approximates the preceding, but it is somewhat smaller and on the hindwing beneath it has a straight, equally broad, silvery white band. — Common from Mexico to Brazil.

E. zestos Hbn. (166 g) resembles *asander*, but it is more brownish-yellow and has a broader ochreous- *zestos*, yellow discal hyaline band of the forewing; on the hindwing beneath the silvery-white band is absent altogether. Guiana.

E. gaumeri Godm. & Salv. is like *exadeus* (166 e), only smaller and beneath the hindwings are *gaumeri*, unspotted. Described from Mexico.

E. enispe Hew. (166 g) looks above somewhat like *exadeus*, but it is quite different beneath; the *enispe*, hindwings are of a dull greyish-brown, strewn darker, with a darkened basal part and 2 transverse lines in the middle, the proximal one of which is broader and rather straight, the distal one finely undulate. — **rochus** *rochus*, Plötz (= *bochus* Mab.) only differs by the absence of the small apical spots. Colombia and Brazil.

E. barisses Hew. is a very variable species, above very much like *tityrus* (166 e), but with somewhat *barisses*, lighter discal spots, beneath like *enispe* (166 g), though the space between the two distal transverse lines on the forewings and hindwings is darkened by brown, whereas the marginal area of the hindwing is of a lighter, violet-grey tinge, the proximal transverse band is distally more or less broadly bordered with silvery white, towards the costal margin torn. In the smaller f. **tmolus** Plötz (166 g) from Argentina the silvery band is narrower *tmolus*, or almost extinct, the colouring above darker; in **busiris** Stgr. from Peru the hindwing shows a more strongly *busiris*, bent and equally broad silvery band. The type flies in Brazil. — **argentea** Mab. from Argentina has on the *argentea*, hindwing beneath a straighter silvery band, and the distal margin of all the wings is longer lilac-grey.

E. haitensis Mab. & Boull. is jet-black, bases of wings and body of a dark red with a grey lustre. Fore- *haitensis*, wing with 2 apical dots. Median band composed of small spots. Under surface of forewings violettish-red with a black inner-marginal area. On the more violet under surface of the hindwing the white band is broad; fringes grey, scarcely interrupted. In spite of the differences mentioned, it is, according to its authors, presumably only an insular form of *asander*; the contours of wings are entirely like those of *enispe*; Hayti.

10. Genus: **Proteides** Hbn.

Very similar to the preceding genus, but the forewings still longer and the apex strongly extended, without a costal fold; the cell is $\frac{3}{4}$ of the length of the costal margin. Only one variable species with 2 separate insular forms:

P. idas Cr. (= *mercurius* F.) (166 d) entirely resembles above *Ep. exadeus*, but beside the longer *idas*, shape of the wings it has a somewhat brighter red-yellow basal part. Beneath the colouring and marking of the hindwings is quite different; whitish-grey, some places tinted light violet and strewn darker, with a dark brown basal part and proximal margin, a postmedian, irregularly dentate band, being extinct in the middle part and towards the costal margin indicated by single small spots, and forming at the proximal margin a thick, dentiform spot; anal lobe likewise dark brown. The type is distributed from Arizona through Central and

South America and in some districts rather common. The butterfly has a very swift flight. — The larva is honey-coloured, strewn dark brown, with brown transverse bands and a red lateral stripe and head. It lives on tree-like Papilionaceae, also Cassia, and changes in to a bluish pupa in a leaf drawn together like a trough by means of 2 threads. — In Cuba flies *sanantonio* Luc. (167 a) with an extinct discal macular band of the forewing, only at the costal margin there is a small spot. — In Porto Rico there occurs another form: *gundlachii* Plötz (166 d), in which the hindwing beneath is unicolorously red-brown and without any whitish-grey dusting. — In ab. *angasi* Godm., likewise from Porto Rico, the transparent spots on the forewings are absent altogether, nor is there any white at all on the hindwings beneath.

11. Genus: **Chrysoplectrum** Wts.

Some smaller species with a moderately thick antennal club bent like a hook, with a very slender, long terminal half. Forewing very broad owing to the short proximal margin and long distal margin; ♂ with a costal fold; cell of hardly $\frac{2}{3}$ of the length of the costal margin. Hindwing at the base of the costal margin very concave, rather long, distal margin in the ♂ straight, in the ♀ convex. At the anal angle a dentiform lobe. The posterior tibiae show a cover of long fringes and 2 pair of spurs; the posterior tarsi are beneath provided with 2 dense rows of lustrous golden pricks.

otriades. **C. otriades** Hew. (= *euphronius* Mab.) (167 a) is above unicolorously blackish-brown with white fringes, beneath with a lighter inner-marginal area of the forewing and a greenish basal part, and on the hindwing with an antemarginal band consisting of small, light lunae and showing near the proximal angle 2 more purely white, small spots. From Brazil, Amazon District. — From Bahia the form *bahiana* Plötz (167 a) is described with also above greenish bases of the wings and body, the fringes not being purely white, but yellowish; the under surface is lighter brownish, the inner-marginal area of the forewing still lighter, the antemarginal line almost without any white.

perniciosum. **C. perniciosum** H.-Schäff. (= *epicincia* Bltr.) (167 a) differs from *otriades* by 3 large white discal hyaline spots of the forewings. Beneath on the hindwing the antemarginal band is only indicated, the green very much confined. Colombia, Brazil. — *eudicus* Mab. shows light yellow instead of whitish spots of the forewings, the spot below vein 2 being absent, metallic green hair cover the whole prothorax and the bases of the wings; from Santa Catharina, the type in the Coll. STAUDINGER in the Berlin Museum.

justus. **C. justus** Plötz (168 e), according to the figure, is very much like the preceding, the hyaline band is only somewhat steeper and has near the proximal angle another small square spot. GODMAN places the species to *Thymeles* beside *pervivax*. Patria unknown.

12. Genus: **Acolastus** Scudd.

Anatomically very closely allied to the preceding genus, but the ♂ is without the costal fold. The cell is somewhat longer than $\frac{2}{3}$ of the costal margin. Posterior tibiae fringy, with 2 pair of spurs, the tarsi without any pricks. HUEBNER calls the genus *Polygonus*. Only 1 species:

amyntas. **A. amyntas** F. (= *lividus* Hbn., *savignyi* Latr.) (146 g) is a well-known species, above blackish-brown with a light violet lustre, 3 large discal spots and 3 very small apical spots. Beneath the hindwings are lilac-grey with 2 blackish macular bands. Common and very widely distributed from Mexico across South America.

13. Genus: **Telegonus** Hbn.

Large, strong animals. Antennal club but little and quite gradually thickened, bent almost rectangularly; the 3rd palpal joint is very short. The forewings are broad, the apex of the wing extended, whereby the distal margin is much longer than the proximal margin. The cell is longer than $\frac{2}{3}$ of the costal margin, the ♂ without a costal fold, whereby the species are separated from the following genus. The lower median vein rises 3 times as far from the cell-end as from the base, the upper one more than twice as far from the base as from the cell-end. The hindwings are lobate at the anal angle, the distal margin is roundish, the middle radial is absent. The posterior tibiae are fringy, with 2 pair of spurs. Numerous, often very similar species from Central to South America.

anaphus. **T. anaphus** Cr. (167 a) is above brown, on the body and bases of wings with a faint green reflection, the anal part of the hindwing yellow, beneath more extensively so and with 2 darker macular bands. From *anaphides*. Mexico far across South America. — In *anaphides* Mab. & Boull. the hindwing shows the yellow marginal band reduced to a bright yellow, more prolonged than broad spot between vein 1 b and 2, and the brown of the ground of the wings does not extend pointedly to the anal angle. Beneath the bands are very distinct, and the marginal band is pale yellow, strewn with small dark scales. Brazil.

T. leucogramma *Sepp* is a doubtful animal, having no more been recognized since SEPP's figure. *leucogramma*. It looks like a gigantic *anaphus*, with a narrow white transverse line at the cell-end, something like in *E. eurycles* (160 e). Described from Surinam.

T. chiriquensis *Stgr.* (= *meretrix* *Hew.*, *weymeri* *Plötz*) is above blackish-brown, with more prominently dark transverse bands and metallic blue bases of wings and body. Beneath similar to *anaphus* (167 a), the ground-colour lighter, more reddish, the yellow marginal area extended to the anterior angle and strewn with reddish-brown. Panama to Colombia.

T. elorus *Hew.* (= *blasius* *Plötz*) (167 b) resembles *chiriquensis*, but the hindwings are at the anal angle rounder, the colour above is still blacker, so that the transverse bands are scarcely noticeable. The marginal yellow of the hindwings beneath is very pure at the anal angle, upwards brownish. Brazil, Colombia, Bolivia.

T. ampyx *G. & S.* (172 h) looks above like an *anaphus* (167 a) without any yellow at the hindwing; body and bases of wings without any blue. Beneath also like *anaphus*, but without the yellow marginal part of the hindwing. The inner-marginal area of the forewing is lighter, yellowish-grey. Mexico to the Amazon.

T. alpistus *Mab.* is above dark brown with a reddish reflection with 2 very clear transverse bands, the proximal one of which is interrupted by spots. Beneath yellowish-brown with 2 transverse bands on the hindwing, the distal one being distally dentately bordered with yellowish, behind it the border is blackish. Brazil. — **cubana** *Mab. & Boull.* is above lighter, the fringes on the hindwings yellowish-white; beneath the yellow border of the distal transverse line of the hindwing is more sharply dentate and clearer. From Cuba.

T. galesus *Mab.* is a large, above somewhat lighter species, with a feeble dull green tinge on the body and bases of wings. The dark bands are on the forewing below the median closer together than in the other species. Beneath still lighter with distinct bands and a dark spot at the base of the hindwing. Brazil, Bolivia. — **grenadensis** *Schs.* is presumably only a darker form with more distinct transverse bands from the West Indies (Grenada). Expanse of wings: 44 mm.

T. creteus *Cr.* (167 d, e) is the chief representative of a group being difficult to distinguish, and which has not yet been fully cleared up; we will therefore consider the nearest allies only as forms of this species. Above all are alike, blackish-brown, with 2 rather distinct dark transverse bands and a metallic blue base of the wings, and body. Beneath somewhat lighter and of a more reddish tone, with the same, but here more distinct transverse bands and a large, white discal spot of the forewing, which in *creteus* extends only to the middle of the two lower median veins and does not touch the cell; the costal margin remains dark. Brazil, Colombia. — **parmenides** *Cr.* shows the white spot much larger, upwards narrower and extending almost to the costal margin strewn with blue; the base of the hindwing is strewn with yellowish, and the distal transverse band is bordered by a lighter tinge towards the margin and shows near the anal angle two white spots. Guiana. — **hopfferi** *Plötz* from Mexico to the Amazon is somewhat smaller, the white spot similar as in the preceding, somewhat narrower, extending to the white costal margin; also on the hindwing the costal margin is at the base broad white. — **pseudochalybe** *H.-Schäff.* (= *alector* *H.-Schäff.*) (167 e) is still smaller, the white spot as extensive as in *creteus*, but easily recognizable by 2 white spots above each other below the costal margin of the forewing. Here the bases of the wings are also beneath scaled blue; on the hindwing both bands are flown together into a dark median area. Brazil. — **siges** *Mab.* has a more metallic green body and bases of wings. Beneath there is instead of the white spot a greyish-white light part between the bands, extending to the cell; on the hindwing the transverse bands are flown together towards the costal margin. Brazil. — **cretellus** *H.-Schäff.* (167 b) is quite similar to *creteus*, but beneath it has a metallic green costal margin of the forewing; instead of the white spot there is also here only a greyish-white light patch not extending up to the cell. On the hindwing the distal band is distally bordered by a lighter tinge. Brazil. — **bifascia** *H.-Schäff.* is beneath of a more yellowish tone than the other species, the white spot very large, extending to the proximal angle, dusted with grey; the bands of the hindwings are closer together, though not confluent. Brazil. — **jaira** *Btlr.* (= *cretellus* *Plötz* nec *H.-Schäff.*) (167 d) has very much more distinct dark bands, the proximal one on the hindwing very much interrupted, between both near the costal margin an isolated spot. The white spot of the forewing is extended to the base and strewn with brownish; it does not reach the cell.

T. cassander *F.* (= ? *vespasius* *F.*, *elorus* *Plötz*) is above very deep blackish-brown, the bands still darker; the distal one on the forewing describes a regular arc round the cell. Body and bases of wings scantily strewn with blue. Beneath the hindwings are quite black, without any bands, strewn with small ash-grey scales. The species only flies in Cuba.

T. jariba *Btlr.* is a doubtful species from Cuba, the description runs quite similarly. According to the figure by PLÖTZ, it is somewhat smaller, and the hindwings beneath are without the grey scaling.

T. hahneli *Stgr.* (167 b, c) is very similar, but lighter, of a more reddish tone, the transverse bands

looking somewhat dentate, owing to prolongations on the veins. Body and bases of wings without any green or blue at all. Beneath the same, only somewhat lighter. Colombia.

- xagua*. **T. xagua** *Luc.* (= malefida *H.-Schäff.*) (167 d). Above black with a blue basal half and body, also beneath the base of the forewing is blue; in the middle of the costal margin there is a square white spot which may occasionally be absent. The hindwing only shows a faded, darker median band. Cuba.
- hurga*. **T. hurga** *Schs.* seems to belong here. Above brown, towards the base green, the hindwing exhibits a darker submarginal shade which also becomes prominent on the lighter under surface and is distally bordered with yellowish. Expanse of wings: 41 mm. Peru.
- pheres*. **T. pheres** *Mab.* (167 e) is above the same; beneath the marginal area on both wings is lighter, rosy-grey, in front of it a broad, uninterrupted, black band. Brazil, Colombia, Peru, Paraguay.
- habana*. **T. habana** *Luc.* (167 d). Above black with a metallic blue base and body, beneath brown, before the margin on all the wings whitish with brownish-grey scales. Cuba.
- latimargo*. **T. latimargo** *H.-Schäff.* (= cartomes *Mab.*, grullus *Mab.*) (167 c) is above the same, but the hindwing is more extended at the anal angle. Beneath the grey marginal area is present only on the hindwing and twice as broad as in *habana*. The forewing shows towards the costal margin 2 dark macular bands. Brazil, Colombia.
- alardus*. **T. alardus** *Stoll.* (167 c) is larger and distinguished on the hindwing beneath by the very broad whitish-grey marginal band scantily strewn with greyish-brown and being continued yet for some distance at the proximal margin; in *latimargo* it is blackish-brown. The forewing has likewise a light marginal band, parted and proximally bordered by dark macular bands. Distributed from Mexico to Brazil and Colombia and mostly common.
- heriul*. **T. heriul** *Mab.* Above not different from the preceding. Beneath the light marginal band is absent altogether, only on the forewing it is indicated by few small whitish scales; the forewing shows a broad black postmedian band which is interrupted below the apex. Described according to a ♀ from Brazil.
- megalurus*. **T. megalurus** *Mab.* (= consus *G. & S.*) (167 e) is at once recognizable by the anal angle of the hindwing, which is extended like a tail. Beneath the costal margin of the forewing is white as far as the middle of the cell, the wings show a violettish-grey marginal band which is broader on the hindwings. Mexico.
- apastus*. **T. apastus** *Cr.* (= acastus *F.*) (167 e) initiates a series of species exhibiting on the forewing an oblique, white hyaline band. The fringes of the hindwings are speckled black and white. Beneath the hindwings are strewn with greenish-yellow scales and show 2 indistinct, darker transverse bands. Guiana, Brazil, Peru.
- janeira*. **T. janeira** *Schs.*, according to the description, looks exactly like *Th. aulestes* (168 d). On the brown under surface of the hindwing, strewn with yellowish, we only notice a large, yellowish spot near the middle of the proximal margin. Expanse of wings: 49 mm. Rio de Janeiro.
- alector*. **T. alector** *Fldr.* (168 c) is a doubtful species and belongs perhaps to *Thymeles*. Recognizable by the white costal margin beneath on the fore- and hindwings, and by the large white spot in the disc of the forewing; the hindwing shows 2 thick, blackish-brown transverse bands. Bogotá.
- pertinax*. **T. pertinax** *Sepp* (= schelleri *Ky.*, alector *H.-Schäff.* nec *Fldr.*) (167 f) is somewhat smaller and very similar, but beneath it has neither on the fore- nor hindwings a white costal margin. The dark transverse bands are distally somewhat lighter, yellowish. Surinam.
- neobulus*. **T. neobulus** *Mab.* differs from the very similar preceding species by the hindwing beneath being darker in the basal half than in the marginal area, both being parted by a light yellow band from the costal margin to the anal angle, being divided into regular spots by the veins, the two lowest spots being white and more posteriorly removed. Brazil.
- eudemus*. **T. eudemus** *Mab.* is another doubtful species and perhaps only a darker form of *Thymeles passalus* (p. 866). Base of wings and body suffused with a deep dull green. Beneath monotonously black, only the proximal margin of the forewing lighter, somewhat reddish-brown. Described according to a ♂ from the Chiriqui.
- virgatus*. **T. virgatus** *Mab.* is larger than the preceding; above more brown, and the bases of the wings and the body with rusty-yellow, instead of green hair, otherwise marked the same with the oblique white hyaline band of the forewing. Beneath the same. Anal angle of the hindwing extended in a hook-like bow. Described according to a ♀ from Pebas.
- probus*. **T. probus** *Mschlr.* (168 d, e) certainly belongs into a special genus, and is sexually very dimorphous. The ♂ is coloured like the preceding species, but on the forewing it has instead of the oblique hyaline band 2 large, four-cornered spots obliquely above each other, and on the hindwing a curved row of black punctiform

spots. The ♀ is black with lustrous violettish-blue proximal halves of the wings, otherwise marked like the ♂, but the proximal discal hyaline spot is very much larger and oblong, the distal one much smaller. Surinam.

T. tritonae *Weeks* and **T. finitimus** *Weeks*. We have had no access to the descriptions of these *tritonae*,
two species. *finitimus*.

14. Genus: **Physalea** *Mab.*

It has somewhat longer and ascending palpi. The inner-marginal vein is inflated in its first two thirds, in its environs the forewing beneath is bare. On the under surface the forewing shows at the rise of the costal-marginal vein a pencil of stiff hair. Posterior tibiae with 2 pair of spurs.

Ph. vulpecula *Plötz* (169 e). The ♂ is above unicolorously rufous, towards the margin somewhat *vulpecula*,
darkened. Beneath darker, almost blackish. The ♀ is much larger, in the apical area of the forewing darkened,
with 2 large hyaline spots, similar as in *probus* (168 e), and on the hindwing with a row of black spots. Brazil,
Colombia.

Ph. sororcula *Mab. & Boull.* The ♀ greatly resembles that of *vulpecula*, the colour is duller, the *sororcula*,
hyaline spots farther remote from each other, rounder and smaller. Beneath yellowish grey, towards the apex
with a violet reflection. The row of spots on the hindwing is composed of smaller spots. Described according
to 1 ♀ from French Guiana.

Ph. pausias *Hew.* (170 b) is very similar, but much smaller, the ♂ above unicolorously rusty-yellow *pausias*,
with a darkened border. The hindwings beneath shows 2 small, indistinct, black dots below the middle of the
wing. Amazon.

Ph. cervinus *Plötz* is also closely allied, but on the forewing it has 2 black apical dots and a small *cervinus*,
white hyaline spot below the lower cell-angle. The under surface is darker, at the costal margin of the forewing
and proximal margin of the hindwing with a dull blue lustre. Brazil.

15. Genus: **Protopenes** *Mab. & Boull.*

The forewing shows near the proximal angle a slight concave indentation. The cell is longer than two thirds of the costal margin; there is no costal-marginal fold. The lower median vein rises near the base of the wing, the upper one above the middle of the cell. The head is remarkably stout, the palpi ascending, with a very short, obtuse terminal joint; the posterior tibiae covered with long stiff hair, in which 2 pair of spurs are hidden. Antennal club rather feeble, the tip, being bent round, is just as long as the other part. Only 2 species:

P. extrusus *Fldr.* (172 d) is black, thorax and base of wings metallic green, the abdomen narrowly *extrusus*,
curled green. At the costal margin and at the cell-end there are yet 2 or 3 metallic green dots each. Hindwing
in the disc with a large triangular spot, and at the proximal margin with a broad, bluish-green ray. Beneath
the hindwing shows an antemarginal row of small, square, bluish-white spots. Colombia.

P. affinis *Mab. & Boull.* is smaller; on the forewing above the green dots are absent, on the hindwing *affinis*,
there is no inner-marginal ray. Beneath the forewing shows at the apex 4 minute, greenish-white spots, the
hindwing in the middle a broad, yellowish-red transverse spot, divided by the black veins, and an antemarginal
row of small bluish spots. French Guiana.

16. Genus: **Thymele** *F.*

Chiefly differs from *Telegonus* only by the absence of the costal fold. A lot of species resembling each other also in their exterior:

Th. fulgurator *Walch* (= *fulminator* *Sepp*, *mercatus* *F.*, *azul* *Reak.*, *trinitad* *Lef.*, *misitra* *Plötz*) *fulgurator*,
(167 f). Above black and of a radiant bluish-green, with a white hyaline oblique band and 3 to 5 minute apical
spots. Beneath more or less rusty-brown, with or without a large white inner-marginal spot of the forewing,
melting away in the oblique band, the costal margin of the hindwing more or less extensively white, in the disc
with 2 blackish-brown transverse bands occasionally flown together to a darkened basal part. From Mexico
to Brazil and Colombia, wide-spread and nearly everywhere common.

Th. naxos *Hew.* (168 a) is above the same. Beneath at the distal margin of the forewing near the *naxos*,
proximal angle a greyish-white spot. The distal band of the hindwing is distally bordered by 8 small, light
rusty-brown spots, in the middle of the wing there is a white discal spot. South Brazil.

- halesius*. **Th. halesius** *Hew.* has above only one minute apical spot and the oblique band consists of 6, not 5 spots. Beneath in the apex of the forewing a grey band. The Hindwings are grey with a black basal spot, with 3 antemedian black spots and 2 black spots near the anal angle. Patria unknown.
- anthius*. **Th. anthius** *Mab.* Forewing slightly angled below the apex, the median band narrow, linear. Beneath it is widened by white marginal scales. In front of the border towards the apex there are greyish-lilac, small scaled spots. The hindwings are black with a bluish-white submarginal band, in front of it small black spots, near the proximal margin a rectangular yellow spot; in the cell and at the base some more bluish-white spots. Bolivia, Amazon.
- brevicauda*. **Th. brevipennis** *Plötz* (= *eniopeus* *G. & S.*, *naxos* *Drc.*) (167 f). The band of the forewing narrow, the lowest spot and the third from below are removed outwards. Fringes above the proximal angle speckled white. Hindwing at the anal angle prolonged. Under surface blackish, hindwing with 2 dark transverse bands. From Panama.
- palliolum*. **Th. palliolum** *H. H. Drce.* The oblique band of the forewing is only composed of 4 spots. Beneath dull blackish, in the basal halves strewn with yellowish, like the fringes. The middle of the hindwing is crossed by a brown macular band. Patria not mentioned.
- fulminans*. **Th. fulminans** *H.-Schäff.* (= *mephitis* *Hew.*) (168 c) is above almost marked like *brevicauda*, the oblique band generally somewhat broader. Beneath dull brown, the basal half of the hindwing almost black, a postmedian, lighter transverse band, which almost turns whitish towards the anal angle. From Mexico to Colombia, Brazil.
- dinora*. **Th. dinora** *Plötz* (168 a, b) is larger than the preceding, the oblique band still broader. The blue of the bases of the wings is dull and hazy, with but little lustre. Beneath dull black, in the cell strewn with yellowish, below the middle behind it with 2 or 3 yellowish-white spots. Peru, Bolivia, Venezuela.
- philistus*. **Th. philistus** *Hpfgr.* (168 d) has beside the 3 or 4 apical spots 3 larger ones below them, extending towards the median band. Fringes of hindwings of a pure white. Hindwing beneath at the border with a very broad, lilac-grey band divided into spots by the veins. Peru, Colombia.
- bolivar*. **Th. bolivar** *Mab.* exteriorly resembles *Eudamus miltas* (161 e) which has the same marking. Spots with a yellowish tone. Bases of wings and body are not bluish-green. Peru, Bolivia.
- egregius*. **Th. egregius** *Btlr.* (168 b) is distinguished by an almost extinct median band composed only of 2 or 3 small spots, in the apex mostly a minute spot. On the blackish under surface of the hindwing 2 dark bands approaching each other or being confluent in the middle. Mexico to Colombia.
- passalus*. **Th. passalus** *H.-Schäff.* is without the small apical spots like the following species. On the jet-black forewing there is only the oblique band formed by 5 equally large white hyaline spots; the lowest spot touches taperingly almost the proximal angle. Bases of wings with a deep bluish-green reflection. Beneath the species is quite black. Brazil. The species greatly resembles the smaller *Telegonus eudamus* *Mab.*
- aulestes*. **Th. aulestes** *Cr.* (= *narcosius* *Stoll*, *colossus* *H.-Schäff.*, *granadensis* *Möschlr.*) (168 d). Above black with a deep slate-blue reflection, at the base with a blackish-green lustre; the middle spot of the oblique band is small and distally removed, the lowest always quadrangular. The under surface is dull black, on the hindwing distally strewn with lilac-grey or greenish, with 2 indistinct, darker transverse bands, on the forewing with a shortened, lilac-grey submarginal band. The ♀ is almost twice as large with much larger hyaline spots. Distributed from Brazil and Colombia to the south as far as Paraguay.
- briccius*. **Th. briccius** *Plötz* (168 c) is very similar, smaller with coherent spots, the lowest of which always terminates triangularly pointed. The hindwing beneath is of a much lighter bluish-grey. Brazil.
- orphne*. **Th. orphne** *Plötz* (167 e). Here the band of the forewing forms more a single ovoid spot. On the hindwing beneath the basal part is quite dark, towards the margin bordered by a lighter band which forms a light spot near the proximal margin. Rio de Janeiro. Perhaps = *Tel. janeira* *Schs.*?
- christyi*. **Th. christyi** *Sharpe* looks entirely like a small *fuligator* (167 f) without any apical spots and with a narrow hyaline band. Beneath the forewings are metallic green as far as the oblique band. Patria unknown.
- pervivax*. **Th. pervivax** *Hbn.* (= *pertinax* *Stoll*) (168 e) is a similar, smaller species. Above like the preceding, but of a more brown ground-colour. Beneath the bases of the wings are likewise metallic green, at the proximal margin of the forewing there is a large white spot. Patria unknown. — In *aleanderi* *Weeks* from Venezuela the discal band is absent.
- mysius*. **Th. mysius** *Plötz* presumably also belongs here, but it has 6 small apical spots in a curved row. The fringes are yellowish. Expanse of wings: 30 mm. Patria unknown.
- enotrus*. **Th. enotrus** *Cram.* (= *lucidator* *Sepp*) (167 f). The median band is composed of coherent quadrangular spots, the second from above appearing more oblong. Beneath on the forewing there are small apical spots.

The hindwings exhibit a yellowish median spot and yellowish dusting outside in front of the distal transverse band. Guiana, Colombia, Peru, Brazil.

Th. orpheus Plötz (168 c) is very much distinguished by a dark blue submarginal band on all the *orpheus*. wings, which is broader on the hindwing and here beneath dusted white; the forewing shows beneath a large, white inner-marginal spot. Pará.

Th. erycina Plötz (168 a) has the forewing somewhat extended below the apex and on the hindwing *erycina*. a prolonged and somewhat hook-shaped anal angle. The spots of the hyaline band are narrow, there may be one or two small apical spots. Owing to the speckled white fringes, the border appears somewhat dentate. Beneath the forewing is spotted somewhat rusty-red below the apex, the hindwing is strewn with lilac-grey with 2 rows of black spots being distally more or less bordered with rusty-brown. Brazil, Colombia.

Th. aulus Plötz (= *fulviluna* Mab.) (168 a) is above very similar, but it has red-brown fringes. *aulus*. Beneath the apex of the forewing is strewn with lilac and at the proximal angle there is a large, white spot dusted with a rusty brown. The hindwing shows only a somewhat curved transverse band reaching neither the costal margin nor proximal margin and being all round bordered with rusty red. Colombia, Brazil.

Th. centrites Hew. is above quite black, only at the apex of the forewing there are 3 minute white *centrites*. hyaline spots, the oblique band is absent altogether; instead of it there is a black antemarginal band, and on the hindwing a black cell-end streak and 1 or 2 spots near the proximal margin. Ecuador.

Th. mithras Mab. The upper surface is coppery brown, on the forewing 2 postmedian, black, *mithras*. dentate transverse lines, between which the ground is lighter, yellowish; a similar yellowish spot is at the cell-end. Hindwings unicolorous. Beneath blackish, the yellow markings clearer and also on the hindwings there are 2 black, undulate transverse lines approaching each other at the proximal margin. Porto Cabello.

Th. telegonoides Mab. & Boull. is above dark brown with a somewhat indistinct, darker, post- *telegonoi-* median transverse band. The hindwings have broad, yellow fringes. The thorax is metallic bluish-green. Beneath *des*. the same, but the hindwing exhibits a broad, yellow marginal spot like in *anaphus* (167 a), but the anal angle itself is brown. Colombia.

Th. gallius Mab. (168 b) still more resembles *anaphus* above, but it is smaller and on the forewing *gallius*. it has very small white apical spots. The yellow anal angle of the hindwing is of a different shape and terminates upwards in a fine point. On the under surface the band-marking is rather more indistinct, the yellow spot more extensive. Colombia.

Th. chrysorrhoea G. & S. is similar, but above of a purer black, so that the band-marking is *chrysor-* scarcely prominent anymore; the small apical spots are absent, too. The hindwings are rounder, the yellow *rhoea*. spot narrower. Panama.

Th. phalaecus G. & S. also looks like a small *anaphus* (167 a), but it has 3 minute apical spots; *phalaecus*. the hindwing is extended to a triangular apex. The under surface is blackish-grey with the same band-marking; also the proximal angle of the forewing shows a yellowish spot. Described from Mexico.

Th. sumadue Lef. is an entirely doubtful species which may also belong to *Telegonus*. The short *sumadue*. description runs: above and beneath brown with a yellowish macular band, larger spots in the middle, very small ones at the apex. Forewing at the base more extensively green than the hindwing. Cuba.

Th. capucinus Lef. Doubtful like *sumadue*. Wings jet-black, towards the base yellowish. Forewing *capucinus*. of the ♂ with a small arcuate streak and beneath with an indistinct spot in the middle. The ♀ has 2 adjacent yellow spots above and beneath. The hindwing is black at the base, beneath also at the proximal margin strewn with red and grey atoms. Cuba.

Th. zopyrus Plötz (= *hydarnes* Mab.) (168 a) greatly resembles *justus* (168 e), but it has somewhat *zopyrus*. rounder hindwings with speckled fringes and on the forewing 3 minute white apical spots. From Brazil.

Th. bridgmani Weeks from Bolivia has remained unknown to us. *bridgmani*.

17. Genus: **Calliades** Mab. & Boull.

It unites the characters of *Cecropterus* and *Thymeles*. The ♂ exhibits a costal fold. The hindwings are long extended in the ♂, more roundish in the ♀.

phrynicius. **C. phrynicius** Hew. (= *viridans* Mab.) (168 c) is a very conspicuous species, looking like a gigantic *Cecropterus*. Brown, on the forewing with a yellowish, little transparent oblique band and a similar distal margin of the hindwing, into which the ground-colour penetrates on the veins in a dentiform way. Brazil.

polias. **C. polias** G. & S. is similar, but it has a white oblique band and unicolorous hindwings without a light border. Body and bases of wings are covered with hair of a somewhat olive-green lustre. Beneath the hindwing shows 2 black macular rows, being distally near the anal angle bordered with whitish. Central America.

rhacoces. **C. rhacoces** Mab. resembles the preceding and differs by a much longer oblique band, almost touching the proximal angle and being composed of yellow spots; the hindwings are likewise unicolorously brown, beneath at the base strewn with yellowish-white with 2 black transverse bands distally bordered with yellowish-white, at the anal angle with 2 distinct light teeth. Above the thorax is haired green, beneath whitish. The species described according to but 1 ♀ from Central America, is perhaps the ♀ of *Cecropterus zentus* Mschlr. (comp. p. 871 (172 d)).

18. Genus: **Orneates** G. & S.

The only species shows the palpal formation of *Thymeles*, the antennae being quite gradually thickened and bent round like a hook. On the forewing the cell is $\frac{2}{3}$ of the length of the costal margin, the costal fold is present, the lower median vein rises close at the base, the upper one near the lower cell-angle. The hindwings are not prolonged, and round at the anal angle. The posterior tibiae show, beside the two pair of spurs, a thick hair-pencil.

aegiochus. **O. aegiochus** G. & S. looks above like *fuligator* (167 f), but the blue or green on the hindwing is very much reduced. Beneath the wings are blackish, on the forewing the proximal half of the costal margin is green, on the hindwing the base is green, in the cell there is a small yellow spot, and the proximal margin is yellowish. Costa Rica, Panama to Colombia.

19. Genus: **Telemiades** Hbn.

This genus resembles on the whole in its characters the *Thymeles*, but the species are all much smaller with shorter and broader wings, particularly the hindwings being broader. The bent tips of the antennae are mostly longer than the thickened other part. The 3rd palpal joint is longer and more porrect. The ♂ shows a costal fold. About 20 species are known; the genus is confined to Tropical America and goes to the north as far as Mexico.

amphion. **T. amphion** Hbn. (= *zethos* Plötz, *antiopa* Plötz) (168 e, f) is a small, blackish-brown species with a black postmedian band, very small apical hyaline spots and a hyaline discal band composed of 4 spots, on the hindwing with 2 black transverse bands. Mexico to Brazil.

lamus. **T. lamus** Mab. is very similar, smaller, strewn over more yellow, the discal band consisting of 3 smaller, more remote spots, the small costal spot being absent. Obidos.

misithus. **T. misithus** Mab. also looks very much like *amphion* (168 e), of a lighter greyish-brown, the discal band like there, but encircled dark; the hindwings are still lighter, at the costal margin silky grey, with 2 dark brown transverse bands. The under surface is ashy-grey with distinct bands. Guiana, Bolivia, Colombia.

lurideolus. **T. lurideolus** Mab. has the same discal band as *lamus*, but the ground-colour is a yellowish red-brown, the hyaline spots are yellow; beside the dark brown, postmedian transverse band there is another short one at the base. The hindwings are of a darker brown, with the 2 indistinct transverse bands. Amazon.

penidas. **T. penidas** Hew. (172 b) is above likewise rusty-brown, but with much smaller and separated discal hyaline spots; the spot in the cell shows 2 distally directed teeth, near the proximal angle there is yet a fifth very narrow spot. The more longish hindwing exhibits 2 darker transverse bands. The type in the British Museum originates from Santarem.

azines. **T. azines** Hew. (168 f). Above rusty-yellow with blackish, dark apical half and yellowish hyaline spots, on the hindwing with a black cell-spot and a postmedian row of small black spots. Amazon.

perseus. **T. perseus** Mab. & Boull. (172 b) is quite similar, the ground-colour somewhat more olive, the 2 discal spots larger, adjoining, the small discal spot of the hindwing smaller, the macular row consisting only of 5 minute spots. Described from Surinam.

iao. **T. iao** Mab. The forewing is deep blackish-brown with 3 minute apical spots and 2 white hyaline spots in the disc: a punctiform spot in the cell and below it another one being twice as long as broad. The hindwing is unmarked with white fringes and a slight angle in the middle of the distal margin. Beneath the forewing

shows an oblique band composed of 5 white spots; the hindwing is yellowish in the basal half; in the black distal part there are 2 yellow dots above the cell and 2 distally to them. The species described according to one specimen from the Coll. STAUDINGER, perhaps does not belong here.

T. avitus Cr. (168 f) is above rusty-yellow, in the ♀ more yellowish-grey with 3 apical and 3 discal *avitus*. hyaline spots, the 2 middle ones forming a jacent U, the small third spot being situate outside; besides there are 2 rather indistinct transverse bands, and on the hindwing there is a median spot and a brown post-median band. Beneath more yellow, in the ♀ with more distinct spots. Guiana to the Amazon.

T. littera Mab. (169 a) is smaller and more slender, resembling *ceramina* above, on top more grey, *littera*. on the forewings similarly spotted as in the preceding: the cell-spot U-shaped, the one below it V-shaped, a third spot behind it, and between the latter and the small apical spots there are yet 2 smaller ones nearer to the distal margin. The hindwing beneath is white with a brown transverse band. South America.

T. ceramina Plötz (169 a) resembles *littera* above, but the 2 small hyaline spots between the discal *ceramina*. and apical spots are absent. The under surface is greenish olive-grey, particularly light is the base of the hindwing, crossed by 2 dark brown macular bands, the distal one being more coherent. From Surinam.

T. megalloides Schs. presumably belongs here. Above brown intermixed with ochreous-yellow hair; *megalloides*. the marking is like in *ceramina*, the hyaline spots small, the cell-spot parted. The under surface is lighter, in the ♀ the base of the hindwing is yellowish-grey, the transverse bands divided into spots. Expanse of wings: ♂ 34, ♀ 39 mm. Described from Peru.

T. cobarus Mschlr. (= *lucida* Plötz) is above rusty-brown, towards the base greenish with similar *cobarus*. discal spots as the preceding, behind them parallel to the distal margin a black submarginal band; a second broad dark band crosses the middle of the wing. The middle of the hindwing is crossed by a blackish transverse band, on both sides of a lighter, red-brown tint; the marginal area is of a pale violet tone. Beneath the basal inner-marginal area is whitish, in it 2 small blackish spots.

T. epicalus Hbn. (= *avitus* Cr. p. p.). Above rusty-brown, on the forewing with 2 small apical *epicalus*. spots, without the discal hyaline spots and with 2 black macular bands being continued on the hindwing. Brazil.

T. diores Mab. & Boull. is very similar, but it has longer hindwings being pointedly extended at *diores*. the anal angle. The apical half of the forewing is blackened; the proximal band is coherent, not composed of spots; on the hindwing the cell-spot is smaller, the proximal macular band less interrupted. South America. — var. **obscurus** Mab. & Boull. is above more blackish-brown, only in the disc of the forewing somewhat lighter *obscurus*. reddish-brown. French Guiana.

T. megallus Mab. is larger, above more blackish-brown, towards the base darker; the marking with *megallus*. the 2 black transverse bands is otherwise rather the same; the proximal one is straight and runs through the middle of the cell. The hindwing beneath is ashy-bluish towards the anal angle, in the ♀ more at the proximal margin, the distal black macular band contrasting sharply with it. Panama.

T. purpurascens H.-Schöff. resembles *nicomedes* (168 e); on the rusty-brown forewing it has 3 small *purpurascens*. apical spots; a straight black band runs through the base of the cell to the proximal margin, another one farther distally bifurcates at the cell-end in the shape of a Y. The hindwing is darker brown with only one band through the middle. The under surface is of a lighter red, the band of the hindwing composed of small square spots, with 2 more spots at the costal margin. Brazil.

T. nicomedes Plötz (168 e) resembles *megallus*, above with a slight olive tint. The transverse bands *nicomedes*. are narrow, composed of spots; the one between the median veins is on the forewing removed far inward, the band of the hindwing begins at the costal margin with an isolated square spot. The under surface has a somewhat violet lustre, the bands are broader and more spotted. In case *nicomedes* Mschlr. from Colombia and Brazil, the description of which runs somewhat differently, should be identified, PLOETZ' species must get a new name.

T. aberrans Mab. & Boull. is above black, towards the base light rusty-brown, on the hindwing *aberrans*. more extensive. The forewing shows 3 small apical spots, a spot at the cell-end and below it 2 more in an oblique line, the lowest being largest. The hindwing shows a black cell-spot and behind it in a curved row small black streak-spots between the veins. The middle of the distal margin is somewhat angular. Beneath similar, the bases of the wings more yellowish; the disc of the hindwing is ochreous-yellow with 2 rows of small black dots, the proximal one composed of 2, the distal one of 3. French Guiana.

T. acutipennis Mab. & Boull. has longer forewings with a pointed apex. Above rusty-brown with *acutipennis*. 3 apical and 3 light yellow discal spots; the marking is otherwise the same as in *perseus* (172 a), but the colouring is darker, the spots of a lighter yellow. At the proximal margin of the hindwing beneath there is a dimple with

a hair-pencil at the upper margin, so that the species would have to be placed to the genus *Ablepsis*, if it had no costal fold. Described according to a ♂ from French Guiana.

20. Genus: *Cecropterus* H.-Schäff.

The genus contains more than a dozen of small species greatly resembling each other. The 3rd palpal joint is shorter than in *Telemiades*. No costal fold. On the forewing the upper median vein rises from the lower cell-angle or even somewhat above it. The male hindwings are much longer, in the ♀ round. It is very difficult to tell one species from another species.

- aunus*. **C. aunus** F. (= *zarex* Hbn., *brontes* F., *longipennis* Plötz, *orontes* Plötz) (168 f) has no small apical spots. The fringes of the hindwings are above white only in the costal-marginal half, beneath somewhat farther downward. On the hindwing beneath being somewhat strewn with yellowish, and often appearing in the ♀ rather variegated, there are 2 slightly bent bands bordered with a lighter colour. Widely distributed from Mexico to Paraguay.
- oryx*. **C. oryx** Fldr. from the Upper Rio Negro in North Brazil entirely resembles *aunus* (168 f), but much larger (twice as large as HÜBNER's figure of *zarex*), the band of the forewing above interrupted at the subcostal, the marginal spots and fringes of the hindwing broader and without the dark bands on the hindwing beneath.
- bipunctatus*. **C. bipunctatus** Gmel. (168 f) has 2 apical dots, the lower one may be absent above. The comparatively broad, white oblique band ends rather taperingly at the proximal angle; in its middle there may be a black dot. The whiteness of the fringes of the hindwing extends far downward. From Mexico to Brazil.
- dhega*. **C. dhega** Mab. has 4 apical dots and grey palpi. The white oblique band of the forewing is somewhat curved and terminates round below, the lowest spot is not smaller than the one above it. The fringes of the hindwings are light grey, not white in the upper half of the distal margin. Beneath the hindwing is decidedly yellowish-grey, towards the margin rosy-grey with 2 brown bands, the proximal one blurred, the distal one very broadly outside bordered with a light grey on the outside. From Rio Grande.
- zonilis*. **C. zonilis** Mab. has only 2 apical dots; the white band projects somewhat about in the middle, is otherwise equally broad and terminates round below. Fringes of hindwings above extensively white. On the hindwing beneath the 2 brown bands are united towards the costal margin; the distal one is very broad, below the anterior angle convex and bordered with a sharp light colour; also on the forewing beneath there is a light submarginal line. Central America to Colombia.
- lunulus*. **C. lunulus** Plötz (168 g) has 3 apical dots, the lowest of which projects far distally; the costal-marginal spot of the oblique band is very small. The hindwing is beneath reddish-grey, towards the base lighter, the two brown bands at the costal margin confluent, the distal one near the costal margin forming an angle, below it somewhat concave, bordered with a light colour, the lightest at the anal angle; the triangular space between the two bands at the proximal margin is rosy-grey, at the apex with 2 light dots. The palpi are whiter than in *zonilis*. Brazil.
- reflexus*. **C. reflexus** Mab. & Boull. Of the 3 apical dots the lowest projects proximally by half its width. The white oblique band is very broad, the costal spot narrow, in the middle it distinctly projects, the lowest spot forms on the inner-marginal vein a fine apex towards the base. The hindwings beneath are light grey, marked like in the preceding. Sa. Catharina.
- neis*. **C. neis** Hbn. (168 g) has 3 apical dots. The white band strongly projects distally at the lower cell-angle. The fringes are above throughout brown. Hindwings beneath brown, strewn with yellowish, with 2 brown bands and a very dark border. Palpi ashy-grey. Mexico to Brazil.
- capys*. **C. capys** G. & S. extremely resembles *neis* (168 g); the lowest spot of the band is narrow, terminates obtusely and touches somewhat more than half the width of the spot above it. The sexual organs are very different from those of *neis*. Central America.
- bocus*. **C. bocus** Plötz (= *integrifascia* Mab.) (172 d) is very closely allied to *capys*. The white oblique band does not project so far at the cell-angle. Forewings beneath light brownish-grey, in *neis* almost black; the hindwings are reddish-grey with 2 rather narrow blackish bands. Fringes brown. Guiana, Colombia, Brazil.
- itylus*. **C. itylus** Hbn. (168 g) is smaller, with broader wings, without or with 1 or 2 apical dots, the white band rather narrow, particularly the costal-marginal spot; at the lower cell-angle there is no spot at all, the lowest is narrow and touches the one above it only in the distal half. Fringes of the hindwings grey. Guiana to Brazil.
- cinctus*. **C. cinctus** H.-Schäff. (= *rotundatus* Mab.) (168 g) has 4 apical dots in one line. The lowest spot of the band is distally removed by about a quarter of its width, at the lower cell-angle there is a minute triangular spot. Hindwing comparatively round with white fringes. Distributed from Mexico to Brazil.

C. electrus *Mab.* is very conspicuous owing to its orange-yellow palpi; the forewing exhibits 3 apical dots. The band ends pointedly below. Beneath the hindwing is quite black, only in the disc with few yellow scales. Brazil.

C. zeutus *Mschlr.* (= *koluthos* *Plötz*) (172 d) has no apical dots; the thorax is above olive-green like the bases of the wings. Body beneath yellowish-white. The white band of the forewing is light yellow at the costal margin. Fringes at the proximal angle of the forewing and of the whole hindwing white. Hindwing beneath strewn with greenish, the 2 black bands bordered with a lighter colour. Guiana, Colombia.

C. sulfureolus *Mab.* has a light sulfurous band and 3 apical dots in one line; fringes of the hindwings narrow yellow. Hindwing beneath reddish-grey with 2 darker narrow bands and a dot at the base. Brazil.

C. vectilucis *Btlr.* (168 g) has 4 apical dots, otherwise the same. Fringes of the hindwings more yellowish-grey than the narrow distal margin. Hindwing beneath blackish-brown, similarly marked. Guatemala to Colombia.

21. Genus: **Ectomis** *Mab.*

It has the same characters as *Cecropterus*, but the hindwing is rounded like a lobe at the costal margin and covered with a membrane like a pocket. Beneath the forewing shows a hair-pencil at the base of the lower median vein. The posterior tibiae are covered with long, bent hair and exhibit 2 pair of spurs. Only 1 species:

E. adoxa *Mab.* is quite black, on the forewing with a hyaline spot parted by the veins, in the shape of a short median band growing broader downward; above it at the costal margin the band is continued by white dusting. Beneath similar, but the hyaline band is broadly bordered with white. Described according to a ♂ from Cayenne. In the British Museum there is said to be another quite black animal devoid of the hyaline spot.

22. Genus: **Rhabdoides** *Scdd.*

Antennal club moderately thickened, bent round to a long hook. The 3rd palpal joint is conical and somewhat longer extended. On the forewing the upper median vein rises before the lower cell-angle; the cell itself is covered with short hair. There is no costal fold; posterior tibiae as in *Ectomis*.

R. cellus *Bsd. & Lec.* (= *festus* *Hbn.*) (169 a, b) is above deep blackish-brown with a beautiful chrome-yellow, partly transparent oblique band and on the hindwing with speckled yellow fringes. Beneath the hindwing is strewn with a lilac grey towards the margin and exhibits 2 blackish-grey macular bands. Wide-spread in North and Central America. — From Mexico there is a form before me from Orizaba: **mexicana** *form. nov.* (169 a) in both sexes, with an almost twice as broad, deep orange-yellow band terminating round below, the small apical spots still smaller, reduced to 2, the yellow fringes of the hindwings narrower. — **pseudocellus** *Cool.* from Arizona has also an orange-yellow band, but it is much smaller, with grey fringes of the hindwings, and beneath the lilac-grey scales are absent on the hindwings.

R. casica *H.-Schöff.* (= *epigena* *Btlr.*) (169 b) is dark brown with minute hyaline spots in the disc and before the apex, the hindwing with broadly white fringes. The hindwing is white in the marginal third, otherwise grey, watered with black, with 2 dentate bands bordered with bluish-black. From Arizona to Colombia.

R. tehuacana *sp. nov.* (169 b) I as yet consider to be a distinct species, since there are also typical before me from the same district. It greatly resembles *casica* above, but it is of a somewhat duller, greyer tone, with smaller, partly almost extinct hyaline spots. On the hindwing beneath the white marginal area is much broader, proximally convex, almost without any black dashes, the other space of a pure ashy-grey without the jet-black transverse bands which are merely indicated, and near the proximal margin with 2 whitish spots. The forewing is somewhat more tapering at the apex. From Tehuacan (Puebla).

R. jalapus *Plötz* (169 b) is a doubtful species: above blackish-brown with a dark leaden-grey, curved antemarginal band, and a similar cell-end streak, the hindwings with white fringes. Beneath more reddish-grey with the same marking, but in black; the hindwing is yellowish-brown with 2 blackish transverse bands. The species was described from Jalapa (Mexico) and is perhaps only a variable *M. albociliata* (170 c).

23. Genus: **Bungalotis** *Wts.*

Antennal club gradually thickened and extended into a twice as long, fine, scarcely bent tip. The 3rd palpal joint is scarcely visible. Venation as in the preceding genus. The cell of the forewing is covered with

long hairs, only in *midias* they are shorter. Tibiae as in *Rhabdoides*. The genus contains about a dozen of beautiful, large, very sexually dimorphous species.

- midas*. **B. midas** Cr. (= *rhetus* F., *astylos* Cr., *corentinus* Plötz) (169 c) is above rusty-yellow with few small black spots. Very characteristic are the hindwings, being black at the costal margin, with a deep ultramarine reflection. The ♀ having been described as *astylos* is quite different, much larger, blackish-brown with a discal hyaline band and yellow fringes. Known from Guiana, Colombia, Bolivia, Peru, and the Amazon.
- ramusis*. **B. ramusis** Cr. (= *astrapaesus* Hew., *damias* Plötz) (169 b, c) is darker, more coppery brown, the small black spots partly with pupils, without any blue at the costal margin of the hindwing. Little is known of the ♀, the white spots partly with black rings being extremely variable, unless they be quite different species. Guiana, Colombia, Peru, Brazil, everywhere rare.
- dexo*. **B. dexo** Mab. resembles *nicephorus* (172 b), being above rusty-brown with a row of small yellowish punctiform spots near the border of the forewing. The hindwing shows a small yellow cell-spot and a curved row of 5 similar small spots behind it. Beneath the same, though darker. The ♀ is much larger with broader wings and the same small spots, but the cell-spot of the hindwing is absent. From the Chiriqui.
- nicephorus*. **B. nicephorus** Hew. (172 b) greatly resembles *dexo*, but the forewing is without any marking, and on the hindwing there are 2 small spots in the cell. The ♀ is not known. Described from Colombia.
- zohra*. **B. zohra** Mschr. is smaller than *dexo*, but very similar. The wings are much darker towards the margin; the forewing shows only one small yellowish dot between the lower radial veins. The under surface is monotonously blackish-brown without any markings. French Guiana.
- phraxanor*. **B. phraxanor** Hew. (= *heras* Mab.) (169 d) is above dark brown, towards the margin darker with a large, tripartite, yellow hyaline spot in the disc and 2 or 3 rather large apical spots. In the cell of the hindwing there is a large, oblong spot and behind it a curved row of 5 or 6 black dots which are yellowish beneath. The ♀ is larger, blackish-brown, with 4 light yellow spots forming an oblique median band. Colombia.
- polygius*. **B. polygius** Latr. (172 b, c) is very similar, somewhat smaller and lighter with the same discal spots and a small double dot encircled by black below it. The hindwing also exhibits small, yellow hyaline spots surrounded by black in the cell and a curved row behind them. The ♀ is larger, darker, the spots are narrower, more like a median band; on the hindwing there are only 2 small spots behind the cell-spot. Brazil.
- eripis*. **B. eripis** Hew. (= *etias* Hew.) is of a darker blackish-brown, beside the discal spots of the preceding there is a fifth spot in the cell. The hindwings are marked as in *phraxanor*. Beneath somewhat lighter. The ♀ is more yellowish-brown, otherwise very similarly marked. From Tapajoz.
- erythus*. **B. erythus** Cr. (169 d). This extremely rare species from Peru, known to us only from CRAMER'S bad figure, is not to be confounded with any other by the speckled, somewhat dentate fringes of the hindwings. The ♀ is similar, but it has broader wings. Perhaps it is better placed to *Nascus*.
- salatis*. **B. salatis** Cr. (= *muretus* F., *tychios* Plötz) (169 e). The forewings are above unicolorously rusty-yellow with a black cell-spot, a postmedian row of black streak-spots and a white apical dot; the hindwings are marked the same. The ♀ presumably belonging here is of a lighter yellow with 2 apical dots and a large apical hyaline spot composed of 4 small ones, the hindwings like in the ♂. Colombia. Brazil.
- sebrus*. **B. sebrus** Fldr. (= *pelignus* Hew., *gonatas* Hew., *ophiuchus* Plötz) (169 d) has broad, rusty-brown wings darkened towards the margin. Before the apex a punctiform spot, below it in an oblique line 2 somewhat larger hyaline spots. On the hindwing there is a black cell-spot, behind it in a curved row 5 small black spots, of which that between the median veins is pupilled white. The under surface is more blackish. The ♀ is larger, somewhat lighter, with the same spots, besides with a spot in the cell and a double spot below the submarginal spots. On the hindwing the cell-spot and 3 or 4 of the postmedian row are pupilled white. Colombia, Peru.

24. Genus: **Heronia** Mab. & Boull.

Distinguished by the anal angle of the hindwing being extended into a small, rounded tail, the border of the hindwing being slightly undulate. The second palpal joint is very broad, the 3rd short, ascending obliquely. Only one species:

- labriaris*. **H. labriaris** Btlr. (= *seneca* Plötz) (172 c) is above brown with small hyaline spots: a large square one, exhibiting 2 teeth towards the margin, at the cell-end and a similar one below it, 3 in the apex and 4 below it. Hindwing with 2 yellowish postmedian macular bands and a round hyaline spot in the cell near the base. Patria unknown.

25. Genus: **Discophellus** G. & S.

Antennal club moderately thickened, with a very fine point unciformly turned round. Costal fold present. On the forewing the lower median vein rises nearer to the base than to the upper. The hindwing is somewhat angular before the anal angle and sinuated in the middle of the distal margin; otherwise like the preceding.

D. porcius Fldr. (= *doriscus* Hew., *coccutiens* H.-Schäff.) (169 e) is above of a dim reddish-yellow, *porcius*. towards the border brownish with a cellular hyaline spot on all the wings, which, however, may be also absent on the hindwings; on the forewing there is below it a darker double ring-spot and behind it a series of darker, small ring-spots or punctiform spots. The ♀ has broader wings with more extensive hyaline spots, particularly in the disc of the forewing. Central America to Peru and Colombia.

D. sebalus Cr. (= *crameri* Latr.) (169 f) is scarcely to be mistaken for any other species by the numerous *sebalus*. hyaline spots on both wings, most of which are encircled by dark. The ground-colour is a beautiful, warm, ferruginous brown, towards the border somewhat darker. French Guiana.

D. fulvus Plötz (= *erythras* Mab.) (169 e, f) is a somewhat smaller species of a fiery ferruginous *fulvus*. yellow ground-colour; the ♂ has no hyaline spots, instead of them black dots: on the forewing, a small one at the cell-end and 2 below it situate beneath each other; on the hindwing there is behind the double cell-dot, which may also be confluent, a postmedian row of black dots; the border is very much darkened. The ♀ has in the disc of the forewing 3 discal hyaline spots greatly varying in size. A small apical hyaline spot may be present. *erythras* described by *Mabille* has somewhat smaller hyaline spots hollowed out towards the margin, for which reason it may be separated. Colombia.

26. Genus: **Nascus** Wts.

Chiefly distinguished by the much stronger, cylindrical antennal club; the end, being turned over, is extended into a fine, very long point. Costal fold present. In the ♂ the anal angle is extended into a rather long lobe, in the ♀ the hindwing is broader and often undulate at the border. 18 mostly large, beautiful species.

N. phocus Cr. (= *pherenice* Hew., *morphus* Cr.) (169 f) has dark brown wings with an olive tint, *phocus*. sometimes exhibiting a slate-coloured lustre, with 4 small, yellowish apical spots connected by 1 or 2 small hyaline spots below them with the 4 discal spots. The costal margin of the hindwing is broadly black, and through the middle extend 2 similar faded transverse bands. Beneath the hindwing is more extensively yellow in the disc. The ♀ is much larger with broader, rounder wings, and larger and white hyaline spots. Distributed from Mexico to Brazil and Colombia. — **dianina** Plötz has above bright yellowish-red hindwings, whilst beneath *dianina*. it is much darker, almost black. Brazil, Paraguay.

N. euribates Cr. (= *hesus* Dbl., *gaurus* Plötz, *nicias* F., ? *tychios* Plötz) (170 a) is above bright reddish- *euribates*. yellow with 3 small apical spots and 3 large, yellow discal spots distally gnawed out. The hindwing with a blackened distal margin exhibits a black cell-spot and behind it a row of 5 more spots. Guiana to Brazil. *MABILLE* presumes that *tychios* placed by *GODMAN* as the ♀ to *B. ramusis* may belong hereto as the ♀ or to an unknown species.

N. cous Mschlr. (= *coris* Mab. ex errore, *eugamon* G. & S.) differs from *phocus* (169 f) by its light *cous*. brown wings with white, not yellow hyaline spots, 5 of which are situate in the apex, 4 in the disc. The hindwing is light yellow; in the distal third broadly brownish. Venezuela, Guiana to Brazil. — **solon** Plötz differs by its shorter, small apical spots crowded together, so that the impression of a single oval spot is created; in the disc there are but 3 hyaline spots. On the upper surface the colour of the hindwings and the base of the forewing are more greenish-brown. — **decemmaculata** Sepp presumably also belongs hereto. The markings are exactly *decemmaculata*. as in *cous*. The body, base of the forewing and the hindwing are of a still more intense green, the fringes of the hindwings speckled with black. In case the bad figure is to represent the type itself, *SEPP*'s name would have to be inserted for it. Described from Surinam.

N. phaselis Hew. (= *faustinus* Burm., *coenosa* Mschlr.) (169 d) is above light ferruginous brown *phaselis*. with 5 apical spots and 4 widely separated hyaline spots in the middle, the latter distally gnawed out, and all of them encircled by black. Hindwing in the cell and behind it spotted black. Fringes of hindwings distinctly speckled white. The ♀ is larger with larger hyaline spots, and it is therefore not out of the question that *Bungalotis erythrus* Cr. (169 d) belongs hereto as the ♀. Widely distributed from Venezuela to Argentina almost over the whole of South America.

- caepio*. **N. caepio** H.-Schäff. (170 b). A smaller species, above dark brown, in the disc somewhat lighter, yellowish, with 4 yellow apical streaks and 4 discal spots. Hindwing above unmarked, only beneath spotted black. Honduras to Colombia.
- mermeros*. **N. mermeros** Mab. is much smaller, otherwise very similar. Above lighter brown with the discal spots much more crowded together, so that the impression of a single large spot is created. The hindwing is less extended at the anal angle. The antennal club is much shorter, the point bent down shorter than in *caepio*. Brazil.
- glarus*. **N. glarus** Mab. is dark brown, in the proximal half of the forewing obliquely cut off and in the disc of the hindwing dimly reddish-yellow. The 4 discal spots form an oblique row on the border between the 2 colours; in the apex of the forewing there are only 2 hyaline spots. On the hindwing the usual cell-spot and the bent row of 5 spots behind it. From the Lower Amazon.
- advena*. **N. advena** Mab. very much resembles *glarus* and is above likewise rusty brown, but it has 3 small apical spots; in the disc there are 4 golden yellow hyaline spots only separated by the veins, the one situate below the cell being gnawed out inside and outside. The hindwings are darker. The antennae exhibit a yellow ring before the club. Costa Rica to Colombia.
- gildo*. **N. gildo** Mab. is above dark brown with a remarkably broad costal fold; of the 4 yellow discal hyaline spots the one situate in the cell is gnawed out towards the costa; the spots are besides small, separated far from each other. Hindwing as in the preceding. Coary.
- gizala*. **N. gizala** Möschl. (= *cephisus* Hew., *evathlus* Mab.) (170 a). The brown forewing is haired yellow at the base; at the apex there are 4 apical dots, the disc is traversed by the 4 hyaline spots in the shape of an oblique band from the costal margin to the proximal angle, the lowest being bent somewhat inwards. Hindwing in the middle slightly angled, unmarked. Beneath the proximal half of the wing is unmarked dull yellow. The ♀ is somewhat larger and lighter and more extensively yellow. Panama, Colombia.
- cephise*. **N. cephise** H.-Schäff. (170 b) is above lighter ferruginous brown than *caepio*, the yellow discal spots somewhat more of the shape of an oblique band owing to the lowest spot being enlarged; the 3 small apical spots form a row inwards convex, in *caepio* distally. The hindwings are unmarked, the fringes somewhat speckled. Beneath on the forewing, the proximal margin is whitish, and on the hindwing the postmedian band of spots exhibits two distinct yellowish spots at the anal angle. The ♀ has broader wings and white instead of yellow spots. Brazil. — **N. orima** Schs. I daresay belongs hereto as a form with somewhat more markings: on the forewing there is in the discal spot in the angle between the radial and median vein a small brown dot, and the hindwing shows two darker transverse lines. Petropolis.
- broteas*. **N. broteas** Cr. (169 f) is above blackish-brown with 4 apical streaks and a white oblique band and a punctiform spot in the middle before it. Hindwing in the middle angled, above in the basal part with ochreous-yellow hair, beneath in the proximal half light yellow, at the costal margin with the beginning of a band of black spots. Of this species only ♀♀ are known, of *cous* only ♂♂, so that both may belong together. Guiana, Brazil.
- annulicornis*. **N. annulicornis** Mschl. (170 a) is smaller than *broteas*, above rusty brown, towards the base lighter, on the hindwing very extensive. On the forewing there are 5 small apical spots in a straight line, beside 4 small black dots. The middle is traversed by an oblique band of 4 white hyaline spots from the costal margin to the inner-marginal vein; the two uppermost are the largest and on both sides gnawed out. The middle of the hindwing is traversed by 2 straight rows of faded black spots. The under surface is lighter, otherwise marked the same, but on the hindwing the 2 macular bands are coherent. Here likewise only ♀♀ seem to be known. Nicaragua to Brazil.
- cebrenus*. **N. cebrenus** Cr. (170 b) is known only from the figure. Above blackish-brown, towards the base yellowish. On the forewing there are 3 small apical spots and a straight band of white hyaline spots in the middle, the three upper ones of which are coherent, whilst the two smaller lower ones are separated from each other; in the angle between the median and radial vein there is another small spot. The hindwings are darker brown, unmarked, the body is covered with ferruginous brown hair. The position of the insect described from Surinam remains doubtful.
- orita*. **N. orita** Schs. is known to us only from the description and seems to be most closely allied to *zopyrus* (168 a) placed by MABILLE to the genus *Nascus* as a synonym to his *hydarnes*. Wings dark brown with light olive-brown hair at the base. The forewing shows 3 small white apical spots and a quadripartite discal band, the uppermost spot of which is yellowish at the costal margin, whilst the others are white, transparent. Hindwing extended into a short, obtuse, bent, small tail with white-speckled fringes. Beneath the discal spots are all white, the apex of the forewing is strewn a little with white; the hindwing shows 2 indistinct transverse shades, the distal one being outside analwards spotted whitish. Expanse of wings: 38 mm. Described from Peru.

N. lucca Plötz (170 b) is united with *gizala* by GODMAN, but according to MABILLE it differs very much from it. Above blackish-brown, towards the base and on the hindwings light ferruginous brown; forewing with 3 small apical spots and a discal band as in *gizala* of 4 spots. Hindwing with a bent postmedian row of black dots exhibited beneath as lighter, black-ringed spots. Patria unknown.

N. adrastor Mab. & Boull. (172 b) very much resembles *lucca*, but it is larger, on the forewings the subapical spots are absent altogether, and in the discal oblique band the costal-marginal spot is absent, whilst the hindwings are above without any markings. The fringes are greyish-white, speckled with brown. Beneath the ring-spots of the hindwings are greyish-white, not pupilled yellowish. Described according to 1 ♀ from South America.

N. diaphorus Mab. & Boull. (*Mschlr.*?) (172 b), according to the authors' opinion, may be the ♂ of *adrastor* or *lucca*. In its exterior it entirely resembles the ♂ of *Bungalotis ramusis* (169 c), but it has light, almost white fringes which are dentate and somewhat speckled particularly distinctly on the hindwings; the hindwing is extended and angled on the lower median vein. Described according to 1 ♂ from Surinam.

27. Genus: **Ablepsis** Wts.

Smaller species with a moderately thick antennal club of the shape of a flattened sickle; palpi rising, the 2nd joint closely pressed to the face, the 3rd very short. Costal fold absent. The cell is longer than two thirds of the costal margin. Between the two inner-marginal veins of the hindwing there is a flat depression with a hair-pencil next to it. Posterior tibiae densely fringed, with 2 pair of spurs.

A. vulpinus Hbn. (170 b) is above reddish-brown, on the forewing with 3 small apical dots and 3 large, yellow discal hyaline spots: one being distally gnawed out in the cell, a large, oblong-quadrangular one below it, and a small, quadrangular one at the upper, distal corner of the latter. The hindwing shows the usual marking of the black discal spot and of the row of spots behind it; on the under surface this row of spots is distally of a lighter yellow shade. Brazil.

A. guyanensis Mab. & Boull. differs from the preceding by its more yellowish, towards the margin darkened colour, the discal spots being distally bordered with black, and by 2 more, longitudinal, black spots in the cell. The groove on the hindwing is much deeper, inside clad with yellow hair and white scales, the yellowish-red hair-pencil next to it is much longer. 1 ♂ from French Guiana.

28. Genus: **Porphyrogenes** Wts.

Here the antennal club is very slender, ensiform with a fine point; the 3rd palpal joint is very short, obtusely conical. Costal fold present; the cell of the forewing is as long as two thirds of the costal margin. The upper median vein rises far before the cell-end, the lower nearer to the base than to the upper one; the proximal margin is very convex and covers a lustrous silvery spot of the costal margin on the hindwing, which exhibits a hair-tuft; the anal fold of the hindwing is clad with long, hair-shaped scales. Only one species:

P. omphale Btlr. (168 e) is unmistakable: above black with an orange oblique band, the base of the forewing and the whole middle of the hindwing with a brilliant blue reflection. Amazon District to Bolivia.

29. Genus: **Murgaria** Wts.

Antennal club gradually thickened and ending into a fine point, behind its thickest part unciformly bent. The porrect 2nd palpal joint is densely scaled, the 3rd very short. Costal fold present. The cell of the forewing is of more than $\frac{2}{3}$ of the length of the costal margin; the upper median vein rises more than 3 times as distant from the base as from the cell-end. The hindwing is insignificantly lobated; the transverse vein is straight; the middle radial is absent. Tibiae as in the preceding.

M. albociliata Mab. (170 c) is above black with white fringes of the hindwings and grey fringes of the forewings. On the wings there are two more or less distinct transverse bands formed of dark leaden grey spots. Beneath the ground-colour is more brownish-grey, the marking of the bands blackish. Mexico to Colombia. — **nigrociliata** Mab. & Boull. has quite black fringes and originates likewise from Mexico.

M. leucophrys Mab. from Panama is quite deep blackish-brown without the marking of the bands, with white fringes on all the wings.

M. toxeus Plötz has quite black fringes as *nigrociliata* has, and beneath on the forewing in the costal-marginal half the beginnings of two white transverse bands. Mexico.

30. Genus: **Aethilla** Hew.

This genus contains large, mostly dark insects with triangular hindwings broadly and uniformly rounded off at the border, the chief mark being the upper median vein rising far before the cell-end. The ♂ exhibits a long hair-tuft on the posterior tibiae armed as usually with two pair of spurs; the middle radial is entirely absent. The ♂ has no costal fold.

- echina*. **A. echina** Hew. (170 c) is a beautiful species above purple blackish-brown, with indistinct darker transverse bands. Beneath easily discernible by the beautiful, whitish-blue border of the hindwing, which exhibits yet a crescentiform spot inwards between the median veins and is crossed by a fine notched line. Before me from Mexico, distributed through the whole of Central America to Panama and farther to Colombia and Ecuador. — *oeclydes* is the name of forms in which the light border of the hindwing beneath disappears more or less, so that at last only the crescentiform spot remains, being situate farther inwards. It seems to occur more to the south and is before me from Colombia. — *melas* Plötz (170 c, d) is perhaps also only a quite black form of it, from Rio de Janeiro.
- eleusinia*. **A. eleusinia** Hew. is above dark brown, on the forewing with 2 darker brown bands; hindwing with a cell-spot and a postdiscal, indistinct band; fringes white. Beneath coloured as above, but without the bands and towards the distal margin lighter. Expanse of wings: $2\frac{1}{2}$ inches. From Quito.
- haber*. **A. haber** Mab. is allied to *coracina* (170 c): above deep reddish-brown with a purple reflection and violettish-blue bands and spots, a band at the base of the forewing touching neither the costal margin nor the proximal margin, one in the middle, one oblique spot each at the apex and at the proximal angle; towards the margin lighter reddish or violettish-grey, more broadly so on the hindwing. Beneath more reddish-brown, similarly marked. Expanse of wings: 52 mm. From the Andes of Peru.
- subviolacea*. **A. subviolacea** Mab. is above violettish-black, all the wings above crossed by 3 faded black bands. Beneath the same, but dull, and on the hindwing towards the margin slightly violet or bluish; outside of the black median band there are here 3 white spots with a slight blue tint. Described from Ecuador.
- coracina*. **A. coracina** Btlr. (170 c) is above quite similar; beneath the wings are of a duller brown, both close in front of the margin narrowly strewn with a bluish-white, the hindwing in the basal part quite dark, the distal band broken up into small spots. Amazon District.
- epicra*. **A. epicra** Hew. is above dark brown with white fringes, both pair of wings exhibit near the middle 2 darker transverse bands. Beneath the forewing is as above; hindwing in the anal half of the distal margin grey, above the anal angle with a short, white margin, distally indented. As in *eleusinia*, the distal margin of both pair of wings forms a single bent line; the apex is sharp. Expanse of wings: $2\frac{1}{2}$ inches. Ecuador.
- lavochrea*. **A. lavochrea** Btlr. (= *athymnios* Mschlr.) (170 d) is above lighter and beneath similar to *Telegonus anaphus* (167 a) with a yellow, large marginal spot on the hindwing. In Central and South America.
- memmius*. **A. memmius** Btlr. (170 d) is distinguished by green dusting beneath, particularly towards the margin; towards the anal angle there are 2 or 3 antemarginal, high, yellow crescentiform spots. From Venezuela.
- later*. **A. later** Mab. is above black mixed with a reddish-brown; at the base of the forewing 3 light reddish-brown spots; at the costal margin a large, long, excised spot, from the centre of which a jet-black band extends to the inner-marginal vein, behind it two light rust-coloured brown spots between the median veins; in the marginal area there are two extinct bluish-black bands. On the dark hindwing there is a ferruginous spot at the base, behind it a strongly dentate band of the same colour, behind it a band of violettish-grey spots. Beneath the wings are black in the basal halves, outside slightly reddish-brown, on the forewing with a black band, on the hindwing with a bluish-white one being only distinct at the proximal margin. Peru.
- primus*. **A. primus** Plötz, from Brazil, resembles *echina* (170 c) above, the whole basal parts of the wings are very much darkened. Beneath the ground-colour is a dull brown, at the apex of the forewing and at the border of the hindwing very little dusted with a whitish-grey, with a light cell-end spot of the hindwing and two narrow, faded darker bands behind it, the distal one of which parts the whitish-grey marginal dusting.
- nocera*. **A. nocera** Plötz is a smaller species with a somewhat produced anal angle of the hindwing. Above uni-coloured brown, beneath duller with 2 undulate, darker transverse lines and a white limbal line before the brown fringes; before this light line the margin is deeply darkened. From Colombia.
- gigas*. **A. gigas** Mab. The description of this Peruvian species has unfortunately not been accessible for us.
- peruviana*. **A. peruviana** Mab. is somewhat smaller than *coracina* (170 c). Above the wings are black with a reddish-brown reflection. The under surface is of a purer black, on the forewing with a narrow reddish-brown distal margin; the hindwing shows a broader reddish-brown margin. Fringes on both sides black. Peru.

A. buffumi *Weeks* is a species having remained unknown to me, and it seems to me very doubtful-*buffumi*. fully placed here. Above dark brown, strewn with grey except the apex; from the middle of the costal margin across the cell-end to the proximal angle extends a series of very prominent white hyaline spots: 2 small subcostal ones, in and below the cell-end one large one each, and in the angle of the median veins behind it a smaller one; 2 small subapical dots; an antemedian and a postmedian darker band, the same on the hindwing very much dusted with grey. Beneath the same, the hyaline spots more coherent, the proximal angle of a lighter colour, from where a lighter part extends to the apex parallel with the margin. Hindwing with more faded bands. Expanse of wings: $1\frac{1}{3}$ inch. Suapure (Venezuela).

31. Genus: **Achalarus** *Scdd.*

The only species also has rounded hindwings, but with a very slightly produced anal-angular apex, the upper median likewise rises somewhat before the cell-end. The ♀ has no hair-tuft on the posterior tibiae. Costal fold present.

A. lycidas *Abb. & Sm.* (= *lyciades* *Hbn.*) (170 d). Above dark brown with speckled fringes and yellow *lycidas*. discal hyaline spots of the forewing, the middle one being small and quadrangular and protruding before the others towards the margin. Beneath the hindwing exhibits a white marginal area, and it is very much transversely watered with black. North and Central America.

32. Genus: **Cogia** *Btlr.*

Well distinguished by a star-shaped hair-tuft exhibited by the ♂ on the upper surface of the hindwing which is entirely rounded off, not produced at the angle. The posterior tibiae do not exhibit a hair-tuft, the ♂ is without a costal fold.

C. hassan *Btlr.* (170 d) is a small, above dull blackish-brown species with speckled fringes and 4 minute *hassan*. subapical spots on the forewing. Beneath the proximal margin of the forewing is reddish-yellow, the hindwing exhibits 4 whitish undulate lines and the space between the two middle ones darkened. Brazil.

C. cajeta *H.-Schäff.* (170 d, e) is larger, above towards the base faintly haired olive-greenish, beside *cajeta*. the small apical spots with 6 small, white, discal hyaline spots partly bordered with a darker shade. The hindwing exhibits 2 irregularly undulate macular bands. The under surface is lighter yellowish-brown, otherwise marked the same, the distal macular band of the hindwing outside light. South America.

C. hippalus *Edw.* (= *gila* *Plötz*) (170 e) is still larger; the lowest discal spot of the forewing which is *hippalus*. in *cajeta* divided into 2 small ones, is here large, outside and inside somewhat gnawed out. The under surface of the hindwing is light ash-grey, towards the margin almost white, strewn with brownish, with 3 bands of brownish-grey spots. From Arizona to Mexico.

C. calchas *H.-Schäff.* (= *terranea* *Btlr.*) (170 e). Here the discal spots of the forewing are absent *calchas*. except 1 to 3 small yellowish costal-marginal spots below each other. The hindwing is beneath brown, strewn darker, with similar macular bands as in *hippalus*, but instead of the light marginal part there is another marginal band, the median band and antemarginal band being lead-coloured, the apex of the forewing strewn with a whitish grey. South America.

C. valeriana *Plötz* (= *valeria* *Plötz* m. s.) (170 e) is midway between *hippalus* and *calchas*, with *valeriana*. somewhat smaller discal hyaline spots than *hippalus*, whilst the under surface is coloured and marked more like in *calchas*; the basal part of the hindwing is uni-coloured dark. From Mexico.

C. troilus *Mab.* is above coloured like *calchas*, but with broader wings, with 4 small subapical spots *troilus*. in an oblique line; fringes greyish-black. Beneath the forewing is reddish-grey in the two basal thirds, distally lilac-grey, the proximal margin whitish. Hindwing light violettish-grey, with two blackish bands which are very broad and only leave a narrow stripe of the ground-colour between them. Hair-pencil at the proximal margin of the hindwing long, ash-grey, almost white. Bolivia.

C. helenus *Mab.* is above very similar, with 5 small subapical spots. Fringes speckled somewhat *helenus*. darker. Beneath the forewing is brown, at the apex light violet. Hindwing violettish-grey with two regular, dentate, blackish bands. The hair-pencil at the proximal margin of the hindwing is short and of the same colour as the ground of the wing. Brazil.

C. eluina *G. & S.* (170 e, f) is above dull brown with the same small spots as in *calchas*, with 2 ir-*eluina* regular undulate macular transverse bands across both wings. Fringes slightly undulate and particularly on the hindwing speckled somewhat darker. Beneath coloured and marked the same, the forewing somewhat lighter than the hindwing. Mexico and Central America.

punctilia.

C. punctilia Plötz (170 e) is closely allied to *calchas*, but smaller; above the small costal-marginal spots of the forewing are altogether absent, beneath there are 2 light strigiform spots before and close behind the middle. Hindwing violettish-brown with 2 dark brown sinuate transverse bands, the distal one very broad. Marginal area not darker. Santarem.

phlius.

C. phlius Plötz resembles *eluina* (170 e, f), but it is still larger, more blackish-grey; instead of the discal spots a black cell-end spot and one below it; on the forewing an antemarginal, irregular macular band partly spotted white outside. Hindwing as in *eluina*. Brazil.

33. Genus: **Cabares** G. & S.

Chiefly distinguished by the forewing being slightly angled below the apex, so that the apex looks somewhat cut off, and by the forewing being angled in the middle. Only 3 species.

potrillo.

C. potrillo Luc. (170 f) looks above like the hyaline-spotted species of the preceding genus, but the discal hyaline spots form more a narrow oblique band. Beneath the forewing is in the middle light greyish-brownish, the hindwing lilac-grey with 2 brown transverse bands, the distal one of which is cloudily widened towards the margin. Fringes dark brown. Mexico, Central-America, Cuba.

enops.

C. enops G. & S. (172 a) looks somewhat like a small *potrillo* without the discal hyaline spots in the cell and above it, but instead there is a dark spot at the cell-end. Under surface likewise somewhat similar, but the more yellowish hindwing is without the distal median band, instead of which there is an ante-marginal row of moon-spots. Known from Mexico and Honduras.

nicola.

C. nicola Plötz (170 f) somewhat resembles *potrillo*, the discal band of hyaline spots is shortened, it does not reach the costal margin nor has it any small spot below the lower median vein. The under surface is more uni-coloured, the transverse bands are much narrower. Pará.

34. Genus: **Ephyriades** Hbn.

Costal fold absent. On the hindwing the upper median vein rises close at the lower cell-angle, the lower one very close to it. Otherwise very much like the preceding genus, but the wings without the feeble angles.

otreus.

E. otreus Cr. (= clericus F., zephodes Hbn.) (172 a) is a large, brown species with 3 broad, faded darker transverse bands on both wings; the forewing exhibits in the disc behind the cell two large white hyaline spots forming an oblique band, and behind them 6 subapical spots arranged in a bow. Beneath very similar. South America.

pekahia.

E. pekahia Hew. is above dark greyish-brown, at the distal margin and a postmedian transverse band on both wings darker brown. On the forewing there are 8 small, white hyaline spots: 2 in the middle, 3 in a line rectangular to the costal margin behind them, and 3 small subapical spots. Beneath coloured and marked the same. Expanse of wings: 1½ inches. From Venezuela.

35. Genus: **Typhedanus** Btlr.

Here the ♂ shows a hair-tuft on the hindwing above, the costal fold being absent. The apex of the forewing is rather sharp; the anal angle of the hindwing is extended, in *umber* very long. The upper median vein rises on the hindwing before the cell-end, the lower one close at the base. Only 2 species.

umber.

T. umber H.-Schäff. (= zephus Btlr.) (170 f). Above olive-brown with darker transverse bands, 4 apical hyaline spots, 3 hyaline spots below each other in the middle of the costal margin and 2 somewhat larger ones outside and below them obliquely below each other. Beneath marked the same, but the transverse bands are here more distinctly prominent, since the ground is lighter, strewn somewhat darker. Venezuela.

alladius.

T. alladius G. & S. (170 f, g) looks exactly like a small *Teleg. anaphus* (167 a): brown, with darker, faded transverse bands and above with a narrowly, beneath broadly yellow anal angle of the hindwing. Mexico to Colombia.

36. Genus: **Caecina** Hew.

This genus, in contrast with the preceding genus, has beside the hair-tuft on the hindwing above also a costal fold. The forewing has below the apex a slight, somewhat rounded angle, below it the margin is concave. The antennal club is ensiform.

C. calathana Hew. (170 g) in its colouring and marking entirely resembles *T. alladius* from which, *calathana*, however, it is at once discernible by the different shape of the wings. Central and South America.

C. compusa Hew. (170 g) is above and beneath marked the same, only of a duller colouring, the transverse bands somewhat more distinct, without any yellow colour on the hindwing. Amazon District.

C. calanus G. & S. (173 a) is likewise similar to *calathana*, but it has much broader wings. The hindwing is not produced so far at the anal angle and above only the fringes are ochreous-yellow. Known from Mexico, Guatemala and Panama.

37. Genus: **Ancistrocampta** Fldr.

In contrast with the neighbouring genera, the antennal club is here only moderately thickened, at the pointed end angularly flawed, not bent, and at the exterior edge it shows scanty, minute bristles. Costal fold absent; on the forewing the upper median vein rises far before the lower cell-angle. The posterior tibiae armed with 2 pairs of spurs exhibit a bent hair-pencil.

A. hiarbas Cr. (= *ozias* Hew.) (170 g) is above deep velvety brown with a large, yellow discal hyaline spot narrowed on both sides, very much widened beneath at the proximal angle. The hindwing is beneath brownish-or violettish-grey with a dark brown costal-marginal spot and such a transverse band from the middle of the proximal margin to the costal-marginal angle. South America.

A. celsus F. (= *clearchus* Plötz) (171 a) is similar, smaller, and the yellow discal band extends in about the same width from the costal margin to the proximal angle; the under surface is just like above, only of a duller brown. There are doubts about the nomenclature of this species and of the preceding. We are of GODMAN's opinion that it is thus most correctly placed. South America.

A. amyrrus Mab. is closely allied to *hiarbas*. The ground-colour is above and beneath uni-coloured black; the yellow discal band begins broadly at the costal margin and grows narrower towards the proximal margin; beside it there is a similar, yellow subapical hyaline band divided into 6 small spots by the veins. The palpi are dirty yellow, haired black. Colombia. Rio San Juan.

38. Genus: **Spathilepia** Btlr.

Well distinguished by the shape of the wings with a very much projecting angle below the apex of the forewing and a dentate border particularly on the hindwing, which is somewhat produced in the middle of the distal margin and at the anal angle. Costal fold present. Posterior tibiae with hairy fringes and 2 pairs of spurs. Only one species.

Sp. clonius Cr. (171 a) is above black with a white discal hyaline band, a series of minute apical spots and between them with a small oblong spot. Beneath very variegated with the same marking of the forewing as above, only the oblique band being much broader at the proximal angle. Hindwing brownish, at the costal margin mixed with bluish-grey and with large, dark brown spots bordered with light, the largest at the costal margin triangular, with its apex crossing the cell and extending close to the proximal margin. Very common from Mexico almost through the whole of South America.

39. Genus: **Oechydrus** Wts.

The shape of the wings is very much like in the preceding genus, but the margin is not dentate, but entire. Costal fold present; all the rest is like the *Spathilepia*, except the hindwing of the ♂ exhibiting a hair-tuft on the upper surface.

O. chersis H.-Schäff. (= *evelinda* Btlr.) (171 a) shows above the same colouring and marking as *Sp. clonius*, and there also exist resemblances beneath; the apex of the forewing and a large discal spot on the hindwing are reddish-brown; the costal margin and base are mixed with a bluish-grey. Brazil, Amazon.

O. ochrilinea Schs. is the same, but the discal band is yellow. Described from Peru. *ochrilinea*.

O. aziris Hew. (171 a) differs above by only one small hyaline costal-marginal spot and the absence of apical spots. The under surface is very variegated: forewing light reddish-brown, towards the apex speckled with a whitish-grey, with some black antemarginal spots, the margin itself being more grey. Hindwing light ash-grey with some dark brown spots partly tinted white on both sides. Rio de Janeiro.

40. Genus: **Thorybes** Scdd.

The genus is closely allied to *Cogia* and chiefly differs by the absence of the hair-tuft on the hindwing. Costal fold absent.

- mexicanus.* **Th. mexicanus** H.-Schäff. (= nevada Scdd., ananius Plötz) (171 b). Above brown with scanty, small discal hyaline spots; fringes of the forewings speckled, on the hindwing light, almost unspeckled. Beneath the brown wings are very much strewn with a whitish-grey towards the margins, unmarked, before this the hindwing shows two broad, faded transverse bands. From the Rocky Mountains through California to Mexico.
- daunus.* **Th. daunus** Cr. (= bathyllus Swsn.) (171 b) is similar, larger, with larger hyaline spots and also on the hindwing with somewhat speckled fringes. Beneath likewise similar, but the marginal area is not so light strewn whitish-grey, the transverse bands are more or less lead-coloured. In the south of the Atlantic United States. — The green larva with a yellowish subdorsal stripe, red collar and black head, lives on Papilionaceae, such as Glycine, and pupates on the stalk of the food-plant.
- paucipuncta.* **Th. paucipuncta** Dyar (171 c) is very closely allied to *daunus*, somewhat smaller, the discal spots very much reduced, often scarcely visible. Beneath likewise similar, the forewing towards the margin scarcely brightened up, the hindwing only in the middle of the distal margin, otherwise with the same transverse lines; fringes of the hindwing almost white. Sierra de Guerrero (Mexico).
- mysie.* **Th. mysie** Dyar (171 b, c) is considerably larger, above very light fawn-coloured, the hyaline spots somewhat more reduced than in *daunus*, the fringes of the hindwing somewhat speckled. Beneath marked as the other species on a ground very much strewn with a whitish grey, with 2 irregularly spotted transverse bands, the proximal one darker. From Mexico.
- thedeia.* **Th. thedea** Dyar looks above somewhat like *Cogia eluina* (170 e, f): brown with a blackish transverse band through the middle, on the median veins distally dentate, behind it two small white spots in the cell and one at the costal margin, before the apex 4 minute hyaline spots; some more, small, antemarginal spots are ringed blackish: one above the upper median vein, a double one above the lower, and a double one above the inner-marginal vein. Hindwing with traces of a postmedian row of spots. Expanse of wings: 40 mm. Mexico (Tehuacan).
- uvydira.* **Th. uvydira** Dyar (171 c) is the largest, most beautiful species of the genus, above nut-coloured brown, outside darker, with the hyaline spots of *daunus* and very dark-speckled fringes. Beneath the hindwing is almost white in the larger distal half, with 2 fine, distinctly black dentate lines; on the forewing an antemarginal line of light moon-spots. Mexico (Guerrero), taken in June.

41. Genus: **Phaedinus** G. & S.

Very closely allied to the preceding genus, distinguished by a much longer 3rd palpal joint which is porrect; the antennal apex is turned down and shorter.

- caicus.* **Ph. caicus** H.-Schäff. (= moschus Edw., schäfferi Plötz) (171 c) looks above almost like *Thor. daunus*, but the discal spots are somewhat narrower. The fringes of the forewing brownish, speckled darker, the fringes of the hindwings almost white. Beneath the hindwing is not so brightly strewn, with two broad, lead-coloured black transverse bands, the proximal one broken up into 2 spots. Arizona and Mexico.
- aventinus.* **Ph. aventinus** G. & S. (173 b) is somewhat like *caicus*, smaller, with more extended hindwings and quite dark fringes. The hyaline spots of the forewings are much smaller, almost punctiform and more numerous. The under surface is quite uni-coloured dark, almost without any traces of transverse bands. Described from Mexico.

42. Genus: **Cocceius** G. & S.

Distinguished from the preceding only by the presence of a costal fold in the ♂.

- pylades.* **C. pylades** Scdd. (171 b) is the most similar to *Thorybes mexicanus* (171 b), only somewhat larger with somewhat larger discal hyaline spots, all the fringes distinctly speckled. Beneath the marginal part is not so very bright, the 2 macular bands on the hindwing are somewhat narrower. Atlantic States.
- drusius.* **C. drusius** Edw. looks like *Ph. caicus* (171 c), it has less and smaller hyaline spots arranged somewhat differently. The under surface is darker, the bands of the hindwings indistinct; on the ventral side of the abdomen the ventral line is absent; the palpi are dark grey, mixed with brown, in *caicus* yellowish. Expanse of wings: 1.7 inches. Southern Arizona.
- syloson.* **C. syloson** Mab. is as large as *Th. daunus* (171 b). On the forewing there is an oblique band composed of 5 hyaline spots, the spot above the upper median vein projects towards the margin. Fringes of the forewing broad, in the middle dark, towards the apex and proximal angle whitish, the fringes of the hindwing almost white; speckled dark. Beneath the hindwing is blackish, traversed by 2 still darker macular bands. Described from Cayenne.

43. Genus: **Hydraenomia** Btlr.

Contains 1 small species with a shorter antennal tip. The 3 rd palpal joint is thin, bare, porrect. The distal margin of the forewing near the proximal angle somewhat concave. Costal fold present. The distal margin of the hindwing is likewise concavely indented below the middle and on the whole undulately dentate.

H. orcinus Fldr. (= albicuspis H.-Schäff.) (171 c). Above brown, at the base and margin black *orcinus*. with 2 darker transverse bands bordered by large and small hyaline spots on both wings. Beneath the hindwing is almost white with 3 black transverse bands parted by the light veins. South America.

44. Genus: **Drephalys** Wts.

The chief mark of this genus based upon one single species consists in the lower median vein of the hindwing rising close at the lower cell-angle. The ♂ shows a costal fold; the border of the wings is entire, the hindwing at the anal angle produced into a triangular point.

D. helixus Hew. (173 a, b). Above dark brown, at the base haired yellowish-green, on the forewing with *helixus*. 4 large and 3 minute hyaline spots, on the hindwing with 2 yellowish macular transverse bands. Beneath the hindwing shows a broad, white discal band on a lilac-grey ground, reaching neither the costal margin nor the proximal margin. From Panama.

45. Genus: **Paradros** Wts.

Allied to the following genus and also closely approximating *Hydraenomia*. Chiefly distinguished by the prolonged hindwings with an entire margin. On the forewing the lower median vein rises close at the base. The antennae are longer than in *Lignyostola*.

P. phoenice Hew. (171 d) is above blackish-brown with numerous white spots, yellow on the hindwing. *phoenice*. Beneath the hindwing is yellowish-grey in the basal part, in the distal part violettish-grey, between the two colours with a black transverse line. Costal margins orange-yellow. Brazil.

P. eous Hew. (171 d) is smaller, above very similar, but on the hindwing the yellow spots are reduced, *eous*. in the middle there is only an oval transverse spot. Beneath quite different, on the hindwing reddish-brown with a large, reddish-white transverse spot and a smaller, almost square spot in the black anal angle. From Brazil (Pará).

P. alcmon Cr. (171 d) differs by its white hindwing with a broad black border, also beneath coloured *alcmon*. and marked the same. Guiana to Brazil.

P. oriander Hew. is above dark reddish-brown, on the forewing with 2 cellular hyaline spots, 2 behind *oriander*. them and 3 subapical spots; near the proximal margin there are 2 yellow spots; the hindwing shows 2 transverse bands, each of 3 yellow spots. Forewing beneath the same, but at the apex lighter reddish. Hindwing reddish-brown with a round orange-yellow central spot and 2 similar spots near the proximal margin behind the middle. Anal angle black. Expanse of wings; 1.9 inches. Amazon.

P. formosus Fldr. (171 e) entirely resembles *phoenice* above, but beneath it is quite different, in *formosus*. the larger distal-marginal and costal-marginal half violettish-brown or cherry-brown, at the base and proximal margin yellowish, at the anal angle black with a round white postcellular spot terminating in the ♀ like a band into the proximal margin. Widely distributed from Panama to Brazil.

P. dumerilii Latr. (171 e) looks very much like *formosus*, but the white hyaline spots are larger, the *dumerilii*. yellow median band of the hindwing is distally concave. The hindwing beneath is dark brown in the ♂, bluish-grey in the ♀, distally tinted violet, only at the proximal margin yellow, instead of the white central spot there are the yellow spots of the upper surface, in the ♀ much lighter, almost whitish-yellow. From Surinam.

46. Genus: **Lignyostola** Mab.

Antennal club moderately thick, uniformly bent and finely pointed. Palpi porrect, dehiscent, with a slender bare terminal joint. The cell of the forewing is longer than two thirds of the costal margin; the lower median vein does not rise so near at the base as in *Paradros*. Hindwing decidedly lobate, the distal margin before it somewhat excised. Costal fold present. Posterior tibiae densely fringed with 2 pair of spurs, the upper pair short. Half a dozen species from Tropical America.

- lacydus.* **L. lacydus** Drc. (= pamphygargyra Mab., aon Plötz) is a uni-coloured blackish-brown insect with ochreous-yellow palpi. Nicaragua, Panama to Pará.
- crinisius.* **L. crinisius** Cr. (171 e) is above blackish-brown, in the basal half haired ochreous-yellow, at the body olive-green; on the forewing in the cell and below it a hyaline spot distally extended into 2 teeth, 3 minute subapical spots and between them an oblong strigiform spot, below it two more; the hindwing is of a more intense ochre-colour, in the middle traces of a blurred median band. On the under surface the basal parts of both wings are olive-green, the hindwing exhibits in the middle a broad, behind it a narrower ochreous-yellow macular band and a yellowish-white proximal margin. Widely distributed in South America.
- despecta.* **L. despecta** Btlr. (171 f) is above brown, with 2 small square hyaline spots on the forewing. Beneath marked the same, at the base and at the proximal margin of the forewing, and on almost the whole hindwing olive-yellowish. Brazil (Pará).
- ferrugineus.* **L. ferrugineus** Plötz (171 f) is above brown, towards the base fox-coloured, the same on the body and hindwing of which only the apex is dark brown, the distal margin narrow and the anal angle broader dark brown. On the forewing a minute postcellular hyaline spot between the radial and median vein. Bahia.
- epimethea.* **L. epimethea** Plötz (171 f) is somewhat larger than *ferrugineus*, the proximal third of the forewing brighter and rather sharply defined reddish-yellow, with 3 very fine, small subapical spots. Beneath lighter brown, towards the base and at the proximal margin of the hindwing olive-yellowish, on the hindwing traces of a broad, darker, postmedian transverse band. Brazil.
- cydana.* **L. cydana** Schs. has remained unknown to me and, according to the description, it may belong to *epimethea*. Wings dark brown, the basal third of the forewing rusty-yellow. Hindwing thickly haired ochreous-brown, except the costal margin and apex. Beneath lighter brown, at the bases of the wings and at the proximal margin of the hindwing tinted greenish-yellow. Expanse of wings: 46 mm. Petropolis.

47. Genus: **Hyalothyrs** Mab.

Distinguished from the preceding genus chiefly by the posterior tibiae which are without a hair-tuft.

- neleus.* **H. neleus** L. (171 f) is above black, on the forewing with numerous small, white hyaline spots, the hindwing in the disc and at the proximal margin extensively white, in the ♂ somewhat brownish, particularly beneath. Widely distributed in South America.
- priscus.* **H. priscus** Fldr. is described as a dark blackish-brown insect, with 6 white hyaline spots in the disc and 5 small subapical spots in a bent row, the hindwing with a large, white, round discal spot. According to 1 ♀ from the Rio Negro.
- nitocris.* **H. nitocris** Cr. (171 f, g) differs from *neleus* by its entirely black hindwing being white only beneath at the base like the body. Surinam.
- leucomelas.* **H. leucomelas** Hbn. (171 g) has much more extensive hyaline spots on the forewing and is well distinguished by a large reniform, in the ♀ almost circular hyaline spot of the hindwing, whilst beneath the hindwing is all white except the broad black border. South America.

48. Genus: **Mionectes** Mab.

It entirely resembles the preceding genus, but the posterior tibiae exhibit only 1 pair of spurs. Only one species.

- infernalis.* **M. infernalis** Mschlr. (171 g) is above like *nitocris* except much smaller hyaline spots, but it is easily discernible by the ochreous-yellow under surface of the hindwing with a blackish-brown apical spot. Guiana.

49. Genus: **Grynopsis** Wts.

It is unlike the allied genera owing to the peculiar shape of the wings, the hindwing with an undulate border and before the anal angle with a very lobate distal margin. The club of the long antenna is hardly thicker than the shaft, the 3rd palpal joint short, a hidden costal fold present. Posterior tibiae only with terminal spurs.

- coelestis.* **G. coelestis** Dbl. & Hew. (171 g) is above black with a bright slate-blue reflection, large hyaline spots and speckled fringes. Beneath the hindwing is of a deep orange-yellow except the black distal margin. Colombia, Brazil.

50. Genus: **Marela** Mab.

The species on the whole remind us of *Spathilepia clonius* (171 a), by the shape of the wings with the stunted apex of the forewing as well as by the marking and colouring, but they are without the costal fold. The submedian vein is beneath in its whole length set with stiff bristles. The lower median vein rises nearer at the base than at the cell-angle.

M. tamyroides Fldr. (172 d) is above black, at the bases of the wings with some slate-blue lustre, *tamyroides*. with a large tripartite discal spot, a small one below it, 4 small subapical spots and a number of very small ones below them; fringes speckled light. Beneath the apex of the forewing is brightened up by brownish, the inner-marginal area bluish-white, like the base of the hindwing, the hindwing itself being brown with 2 dentate black transverse bands. Colombia, Brazil.

M. tamyris Mab. (172 d) is smaller, the hyaline spots rather larger, in the submedian space there *tamyris*. are two distantly separated spots. The brown hindwing is extensively mixed with white, also at the proximal margin, at the base, however, not white. Amazon.

51. Genus: **Phanus** Hbn.

Antennal club very slender, almost semicircularly bent. Palpi short, appressed. Costal fold present. On the forewing in the submedian area, in the basal half and at the proximal margin with long hair, the inner-marginal part of the hindwing being also densely clad with hair; the anal part of the hindwing is extended into a lobe forming a tooth on the inner-marginal vein. Only one species.

Ph. vitreus Cr. (= *momus* F., *marshalli* Ky.) (172 e). Above black with an olive-brown tint, with *vitreus*. particularly in the ♀ longish hyaline spots in all the cell-spaces, also on the hindwing, though they vary greatly in their development. Widely distributed from Mexico to South America, in open places even in gardens on flowers common.

52. Genus: **Entheus** Hbn.

Antennae as in the preceding genus, but the palpi more porrect and diverging. On the forewing the costal fold is absent. Characteristic are the short posterior tibiae with a hair-pencil and only one pair of spurs, whilst the first tarsal joint is almost twice as long as the tibia, flattened and bulged. The species are distinguished by a very pronounced sexual dimorphism: the ♂♂ are mostly black and orange-red or yellow, the ♀♀ dark brown with large white spots, also on the hindwing, and often with an orange wedge-shaped spot near the base of the forewing. The species being very much alike and the sexes rather indefinite, there is a want of clearness in this genus.

E. priassus L. (= *talaus* L., *peleus* Cr., *telemus* Plötz) (172 e). ♂ above velvety blackish-brown *priassus*. with a broad, orange transverse band, an orange wedge-shaped preapical spot, and with a more transparent, oblong spot projecting from the middle of the transverse band towards the margin. The ♀ is somewhat browner, in the cell there is an orange wedge-shaped spot, a discal transverse-band, 6 subapical spots forming a chain, and a longish spot between these two, as well as a large, round spot in the disc of the hindwing are white, the spots of the forewings half showing through. Fringes black. Widely distributed in South America.

E. cramerianus Mab. (= *talaus* Cr. nec L., *peleus* Cl. nec Cr.) (172 e) is very similar, somewhat *cramerianus*. smaller, stouter, the orange bands much broader, all the 3 spots broadly confluent, so that they enclose a small, black triangular spot. The ♀ still more resembles that of *priassus*, the row of subapical spots on the forewing is interrupted, the discal spot on the hindwing extends farther to the proximal margin and is distally extended to a point, downward somewhat dentate. On the forewing there is another small white spot in the submedian area, the discal spot is interrupted in the cell. Fringes of the forewing near the anal angle white. Guiana.

E. dius Mab. (172 e, f) is larger than *priassus*, in the ♂ the transverse band is very broad, of a richer *dius*. yellow, the spot behind it small, separated from the transverse band and subapical spot, in the basal part of the cell an indistinct orange stripe. At the proximal margin of the hindwing a fold set with white scales. The ♀ likewise similar to *priassus*, but the subapical and discal spots are divided each into 2 groups, the white discal area of the hindwing is very large, the proximal margin white, too. Costa Rica to Colombia.

E. sirius Mab. is a fourth extremely similar species, hitherto ascertained only in the female sex. *sirius*. Spots similar to those in *cramerianus* (172 e). The discal spot in the cell is still farther separated from the lower ones. The white spot of the hindwing is almost quadrangular, its lower edge straight, extending to the grey proximal margin. MABILLE presumes this rather uncertain species to belong to *gentius*, but this is probably wrong. Described from Cayenne.

- matho.* **E. matho** G. & S. (172 f) resembles *priassus*, in the ♂ with more reddish wings and a large, red, basal wedge-shaped spot of the forewing, the discal band of a deeper yellow, the proximal margin of the hindwing broadly whitish. In the ♀ the small spot between the two bands is very small and nearer to the distal band. Guatemala, Nicaragua, Costa Rica.
- concinna.* **E. concinna** Plötz (172 e) looks very much like the ♀ of *cramerianus*, but in the basal part of the forewing there is a large triangular, sulphureous spot, the hindwings are quite yellow with a narrow black border. From Pará.
- lemna.* **E. lemna** Btlr. (= *annae* Plötz, *berytus* Hew.) (172 f). The ♂ is black, with a large yellow basal area inclusive of the costal margin and proximal margin, with two broad yellow oblique bands, often between the two latter with a small yellow spot, hindwing yellow with a black border. The ♀ described as *annae* differs from that of *priassus* by the absence of the white spot below the subapical band and a more extensive, somewhat brownish discal spot of the hindwing. Brazil (Pará).
- gentius.* **E. gentius** Cr. (172 f) almost looks like *lemna*, but the colour is a beautiful orange-yellow, the spot below the subapical band is large, obliquely quadrangular. The body is orange, too. Colombia.
- eumelus.* **E. eumelus** Cr. (= *serenus* Plötz) (172 g) is black with a narrow, in the ♂ shortened orange stripe in the cell and very narrow white oblique bands and spot. The hindwing is in the ♂ orange with a narrow black border, in the ♀ black with a white discal spot. Guiana.

53. Genus: **Cabirus** Hbn.

Almost the same as the preceding, but the posterior tibiae show beside the hair-pencil two pair of spurs. The palpi are more sessile, the 3rd joint short, conical. Only one species.

- procas.* **C. procas** Cr. (= *julettus* Stoll) (172 f) in the male entirely resembles the numerous yellow and black *Cyllopoda*-species of South America: dark yellow with black margins and a black oblique band before the apex of the forewing. The ♀ is quite different, the yellow colour is replaced by white hyaline spots with broad brownish-black veins and folds. Guiana to Peru.

Group B.

In the species of this group the antennal club is mostly not so semicircularly bent, occasionally with an obtuse end. The cell of the forewing never attains two thirds of the length of the costal margin; the middle radial vein always rises nearer at the upper than at the lower one. The anal angle of the hindwing is often extended, forming a lobate or dentiform projection; the middle radial vein is always rudimentary. Most of the nearctic forms exhibit a costal-marginal fold in the ♂, never a discal stigma. In a great number of genera the ♂ exhibits a hair-tuft on the posterior tibiae or forehips; the former always exhibits 2 pair of spurs. All the species of this group, as far as they are known, rest with their wings flatly spread out, frequently on the underside of leaves. (Group A comp. p. 849).

1. Genus: **Garga** Mab.

Antennal club strong, bent, with a short point, the 3rd palpal joint correct, conical. Costal fold absent. On the forewing the upper median vein rises a little before the lower cell-angle, the lower much nearer at the base, on the hindwing with a prolonged anal angle the same. Only one species.

- platon.* **G. platon** Fldr. (= *olena* Mab.). Size of *Sophista aristoteles* (172 g), but the wings narrower, the forewing in the apex, the hindwing in the anal part more produced. Wings above dark brown, forewing speckled grey and black, the discal macula forms an X-shaped spot, before the apex 3 hyaline dots. Hindwing with a whitish, bipartite subcostal macula, the posterior region blackish with 2 grey bands, the proximal margin and anal part densely haired. Under surface ochreous-brown, the hindwing shows beside the hyaline spots above a cell-spot; the small discal bands and the bipartite anal macula whitish in a brown ground, the hindwing with a partly extinct whitish discal band, the proximal margin light with a black subanal macula, before which there is another dark brown one. Palpi, chest and stripes on the ventral sides white. From the Upper Rio Negro and Ecuador.

2. Genus: **Dichelura** Mab.

Antennal club obtuse. Shape of the wings very characteristic: the distal margin of the forewing below the apex produced in the shape of a tooth, the same on the lower median vein, between concave. Hindwing with a long, lobular tooth on the lower median vein with a minute tooth below it, above it and below it deeply gnawed out, the anal angle itself again produced. Only one species.

- tricuspidata.* **D. tricuspidata** Mab. (173 a) is brown with 2 black transverse bands, on the forewing with a hyaline oblique band and small apical spots. Under surface marbled brown with black, torn macular bands. Ecuador.

3. Genus: **Arteurotia** *Btlr. & Drc.*

Only one conspicuous species owing to the hindwing being considerably prolonged at the anal angle and showing a silky lustrous scent-scale spot in the apical half above. ♂ without the costal fold. The antennal club is strong, bent, the final point shorter than half the length of the club, the short 3rd palpal joint obtuse conic.

A. tractipennis *Btlr.* (= *ribbei* *Stgr.*) (172 g) is above olive-brown, before the apex of the forewing *tractipennis* with a velvety-brown triangular spot, in it one, behind it 2 small hyaline spots, before the somewhat darkened border a lighter antemarginal line, in the basal half at the costal margin and below the cell small dark spots. From Mexico and Panama.

4. Genus: **Sophista** *Plötz.*

Antennal club thinner than in the preceding, the final point very slender. Palpi as in the preceding. Hindwing not so much prolonged, more of the shape of a broad lobe, and without the scent-spot; the lower median vein rises in the middle between the base and cell-end. The costal fold of the ♂ is but slightly developed or absent. Three very similar species.

S. aristoteles *Dbl. & Hew.* (172 g). Black, towards the margin with 2 brownish undulately dentate *aristoteles* lines before the somewhat speckled fringes which are bent inward at the apex of the forewing. The middle of the wings is crossed by a white band very broad particularly on the hindwings and extending on the forewing only to the upper median vein and ending broadly rounded above, whilst on the hindwing it extends broadly to the proximal margin. Rio Negro (Amazon).

S. plinius *Plötz* (172 g) is extremely similar, of a somewhat duller shade, the white band narrower, *plinius* ending upward pointed on the forewing, rounded off on the hindwing, the whole proximal margin being left black. Novo Friburgo, Bolivia.

S. calendris *Hew.* (= *clinias* *Mab.*, *epipola* *Plötz*) (173 a). Here the white band on the hindwing *calendris* has changed into a narrow, bent median line parted by the veins, whilst on the forewing it is entirely absent. The distal part of the hindwing and an indistinct transverse band on the forewing are dusted bluish-grey, on the forewing there are inside and outside of it several small hyaline spots, before the border of the hindwing small black internodal spots. Guiana, Amazon.

5. Genus: **Celaenorrhinus** *Hbn.*

The antennal club is only moderately thickened; the palpi are ascending, the 3rd joint very short. The hindwing is here quite round, the distal margin somewhat undulate; the transverse vein is very feebly developed, the middle radial vein scarcely present, the lower median vein rises much nearer at the cell-end than at the base. The posterior tibiae exhibit 2 pair of spurs, the ♂ has besides a hair-tuft at the proximal end. The species are preferably distributed in the Indo-Australian region, about half a dozen are nearctic.

C. eligius *Cr.* (= *hiera* *Plötz*) (173 a) is above brown, in the apex of the forewing there are *eligius* 3 large hyaline spots, below it 2 small ones, in the disc 2 very large ones, behind them 1, below them 2 small ones, at the costal margin a somewhat larger hyaline spot; before the margin and on the hindwing, also in the disc, several small, lighter spots. The under surface is a little duller, on the hindwing the small light spots are more distinctly prominent. From Mexico and South America, widely distributed. — From the Rio Songo from Bolivia there are specimens before me from FASSL: — **songoensis** *form. nov.* (173 b) — of a smaller and *songoensis* neater habitus; the small subapical spots are reduced to small dots, of which the middle one of the 3 upper ones seems to be placed more proximad, the discal hyaline spots are likewise smaller, the hindwing slightly rounder.

C. fritzgärtneri *Bail.* (= *variiegatus* *G. & S.*) (173 b) on an average is somewhat larger than *eligius* *fritzgärtneri* with somewhat narrower wings, the hyaline spots smaller, below the middle of the cell another minute, dark-ringed spot. Hindwing in the disc lighter with a larger dark discal spot and a similar macular band behind it. Mexico and Central America. It flies in December, rests on the keystones in dark tunnels and caves, and on being scared up it flies furiously about, though not into the open air.

C. shema *Hew.* (= *ochrogutta* *Mschlr.*) (173 b) is smaller, darker, the hyaline spots smaller, more *shema* uniformly round and more distantly separated. A small discal spot and behind it a curved row of minute round spots on the hindwing are yellowish, beneath still more distinct, and near the base there are 3 more. From Cayenne.

C. monartrus *Plötz* (= *chiriquensis* *Mab.*) (173 b) has still much smaller spots, the hindwing as *monartrus* in *fritzgärtneri*, but darker. Mexico to Panama.

- astrigera*. **C. astrigera** *Bltr.* is not unlike *monartrus*, larger, the hyaline spots increased: in and above the cell there are 3, the antemarginal row contains 9 spots, and below the cell there is one more. Beneath the submarginal row of spots on the hindwing is brick-coloured reddish. Tapajoz.
- cynapes*. **C. cynapes** *Hew.* Above dark brown, hindwing more reddish. Forewing in front before the middle of the costal margin to the proximal angle traversed by an equally broad, lustrous transparent white band parted by the veins, before the apex with 7 minute hyaline spots in a bent row. Hindwing in the middle angularly projecting. Beneath as above, but the brown area is strewn with an ochre-yellowish tint, particularly at the base and proximal margin of the hindwing; behind the band of the forewing there is a yellow spot, at the cell-end of the hindwing a light streak. Expanse of wings: 2.1 inches. Ecuador.
- vidius*. **C. vidius** *Mab.* is like the following placed by MABILLE into his genus *Narga* which, according to GODMAN is synonymous with *Celaenorrhinus*. It is described, as follows: blackish, at the margin somewhat lighter, at the costal margin and in the cell 1 or 2 darker spots. Hindwing in the disk blacker. Under surface black, forewing watered with lilac-grey, two more distinct patches at the costal margin and apex. Hindwing watered with a deep lilac-grey, bordered by a black band from the costal angle to the proximal margin. A spot at the base and a shade at the posterior margin blackish, in an oblique light appearing as 2 greyish-lilac bands, the broad basal band enclosing a square black spot at the costal margin. Expanse of wings: 19 to 21 mm. São Paulo.
- scopas*. **C. scopas** *Mab.* Blackish-brown, fringes more reddish, speckled darker, forewing with 2 dust-grey spots between the lower radial veins. Forewing beneath blackish with a lilac-grey spot at the apex and 4 silvery streaks at the rise of the upper branches. Hindwing whitish-grey, at the base and distal margin reddish-brown, traversed by a rust-brown band of spots very broad at the costal angle. The middle of the distal margin almost white; before the fringes a lustrous yellow line bordered with black. Expanse of wings: 23 mm. Venezuela (Merida).

6. Genus: **Pythonides** *Hbn.*

The moderately strong antennal club is somewhat bent, but not angularly; the short, obtuse palpi turned in front. The forewing is much longer than the distal margin, the costal margin in some species very convex, the distal margin above the proximal angle somewhat concave. Costal fold absent. Neuration as in *Celaenorrhinus*. Many species show a brilliant blue on the hindwings, particularly beneath, exhibiting a bright gleam when the insect is on the wing.

- cerialis*. **P. cerialis** *Cr.* (= *orcus* *F.*, *cerberus* *Hbn.*) (173 c) is above brown, in the somewhat more prominently dark median band of the forewing there are several small hyaline spots, behind it in the shape of a band bluish dusting, on the hindwing also in the disc. Beneath the hindwing is silvery sky-blue with a black marginal band. According to CRAMER, the larva is dark green with a lighter dorsal line and 2 similar lateral lines and a red-brown head. From Mexico widely distributed in South America. — **majorinus** *form. nov.* (173 c) from Bolivia (Songo) is very much larger and more variegated, more profusely strewn with blue.
- contubernalis*. **P. contubernalis** *Mab.* (= *praxis* *Plötz*) (173 c) is somewhat smaller, of a purer black, on the forewing in the disc and subapically with much smaller hyaline dots, on the hindwing with 2 light blue transverse bands. Beneath the hindwing is light blue with a black marginal band partly broken up into small spots, and 2 or 3 costal-marginal stripe-shaped spots. From Mexico to Colombia, Brazil.
- anicus*. **P. anicus** *G. & S.* (173 c) extremely approximates *contubernalis* and differs by almost or entirely extinct hyaline spots on the forewings and more intensely blue bands on the hindwings. The somewhat different genitals prove the insect to be a good species. Founded on two ♂♂ from Guatemala.
- parallelus*. **P. parallelus** *Mab.* looks somewhat like a large *cerialis* (173 c), in the cell-end two oblong, not united spots, 4 small subapical spots two of which are closer together. On the hindwing the distal one of the blue bands is not bent, but almost parallel to the proximal band, at the costal margin almost united. Fringes black. Hindwing beneath as in *cerialis*. Bolivia.
- cordus*. **P. cordus** *Mab.* (173 c) is very closely allied to *contubernalis*; on the forewing there are only 3 subapical dots; the hyaline spot before the cell-end consists of 3 small separate spots situate in one line below each other. The apical dots are surrounded by a band of blue scales continued in front of the border to the proximal margin. On the blue hindwing beneath the black marginal band is broadly interrupted between the lower radial veins; at the costal margin there are yet 2 large black spots, the distal one of which is continued towards the proximal margin as a more or less complete macular band. Brazil (Sa. Catharina).
- hoyti*. **P. hoyti** *Weeks* has remained unknown to me. Body above brown with golden brown hair, beneath lighter; on the brown forewing there is in the disc a 7-shaped hyaline spot with a streak behind it, below it a similar spot and above the apex of the latter a quadrangular spot; 3 small, oblong subapical spots, before and below which there is a brown, dark area; near the base and below the middle of the cell one dark-brown, not distinctly defined band each. Hindwing above with 2 similar dark brown bands. Under surface

with the same marking on the light brown ground with a darkened costal margin and apex. Suapure (Venezuela). Expanse of wings: 1.8 inches.

P. belti *G. & S.* (= *paterculus* *Hew.* nec *H.-Schäff.*) (173 d) is not unlike *paterculus*, distinguished *belti*, by the longer anal angle of the hindwing, the colour above being more grey, and by 3 hyaline spots bordered with black in the disc of the forewing, as well as 3 subapical dots; particularly the hindwings are marked with more distinct black macular lines. Hindwing beneath radiantly blue with a black costal-angular spot. Nicaragua.

P. lugubris *Fldr.* (= *ophia* *Btlr.*, *sephara* *Hew.*, *cobarus* *Mschlr.*, *ambly* *Plötz*) (173 d). Greyish-brown *lugubris*, with a slight olive tint; a narrow, dark brown antemarginal line somewhat widened at the costal margin and proximal angle; in and behind a darker median band there are numerous hyaline spots. Hindwing at the base with a brown transverse band, apex pointedly produced, before it a small, short, brown streak-spot. Beneath very much duller, without any blue. From Mexico to Colombia and Brazil.

P. truncata *Hew.* (173 d) is similar, easily discernible by less strongly angled hindwings being beneath *truncata*, of a greyish-blue colour except the margin. From Bolivia.

P. paterculus *H.-Schäff.* (= *balma* *Plötz*, *zera* *Btlr.*) (173 c) is easily recognizable by the proximal *paterculus*, angle on the forewing being produced almost in a conical shape, whilst the costal margin appears somewhat concave right before the apex. Of a deep red-brown mixed with slate-grey or violettish-grey, before the margin rusty, below the cell-end 1 or 2 small, roundish hyaline spots. Beneath lighter rusty, two inner-marginal thirds of the hindwing light blue. From Panama to South America. — Small specimens from Bolivia, the hindwings of which are beneath quite rusty yellow without any blue, may be denominated: **deflorata** *form. nov.* (173 d). *deflorata*.

P. menedemus *G. & S.* (173 e) is above of a warm brown with a deep velvety-brown oblique band *menede-* to the base of the proximal margin, the distal margin of the forewing is likewise darkened, before the apex *mus*, there is a smaller spot with 2 or 3 minute hyaline spots. Beneath lighter red-brown, two inner-marginal thirds greyish-white. Panama (Chiriqui).

P. hyacinthinus *Mab.* (= *servius* *Plötz*) (173 e) is larger, otherwise above very similar. Hindwing *hyacinthi-* beneath in the inner-marginal half light blue, in the costal-marginal part darker ferruginous. Nicaragua, *mus*, Panama, Colombia, Bolivia, Peru.

P. scybis *G. & S.* (173 e) is still larger, above of a warm violettish-brown, with more rounded hind- *scybis*, wings, the whole basal parts of the fore- and hindwings occupied by a large, deep velvety brown spot pointedly extended distally at the lower cell-angle on the forewing. On the hindwing beneath the blue is of a variable extent. Distributed from Mexico to Bolivia.

P. phila *G. & S.* (173 e) looks above exactly like *scybis*, but beneath it is entirely without the blue *phila*, colour on the hindwing; the colouring beneath is on the whole darker. Described from Panama; it may be only a form of *scybis*.

P. pelopea *G. & S.* (173 e) is likewise very similar. The upper surface is darker with a black marginal *pelopea*, band being inwardly faded; there is only a small subapical hyaline dot. The under surface is still much darker brown. From Mexico to the Amazon District.

P. erisichthon *Plötz* (= *gellius* *Mab.*) (173 e, f) is allied to the two preceding species, the dark *erisichthon*, basal marking, however, is more interrupted than in *menedemus*; on the hindwing there are in a slightly curved row 4 or 5 darker, small punctiform spots in the middle. Beneath light reddish-yellow or ochreous-yellow, the forewing with a similar, dark brown marking as above, the hindwing with 2 rows of dark dots, the proximal row mostly confined to one costal-marginal spot, and with a large costal-angular spot. Ecuador, Bolivia.

P. nolkeni *Mab.* is twice as large as *hyacinthinus*; the forewing with a large, black spot as far *nolkeni* as the cell-end, covering also the base of the forewing; from the 3 apical hyaline dots a black band extends encircling the cell and turning towards a large black spot bordering on a hyaline dot between the lower radial veins. Wings with an intense violet lustre, at the margin more reddish. The under surface is ochreous-yellow with a faint black marking. Hindwing almost quite whitish-blue, only at the costal-angle ochreous-yellow with a black dot in it. Expanse of wings: 43 mm. Bogotá.

P. insulsus *sp. nov.* (173 f) in its exterior entirely resembles an *Achlyodes*, but according to the neu- *insulsus*, ration it certainly belongs hereto. Large, brown with a violet reflection as *scybis*. The forewing only exhibits 3 small apical hyaline spots, the brownish-black velvety spots in the basal area are arranged in the same way as in *scybis*, but they are much duller and more blurred; from the lower cell-angle a similar nebulous stripe extends to the distal quarter of the proximal margin. Hindwing likewise similar, the dull, postmedian macular band more complete. Under surface dull ochreous-brown with the same marking as above, but very indistinct. According to a specimen of the Collection SERTZ from South Brazil.

- ineptus.* **P. ineptus** *sp. nov.* (173 f) is very different. Above dark violettish-brown, from the cell-end a large, darker, almost oval spot extends obliquely before the middle of the proximal margin, and before the margin there is a dark band, leaving the margin itself lighter; in the middle of the costal margin there are 2 oblong hyaline spots below each other; in the middle between them and the apex 3 minute hyaline spots, between the median veins close below the cell-end an oblong, quadrangular spot and above it a punctiform hyaline spot. Hindwing at the base and behind the middle with a broad band, before the margin with a narrow band. Forewing beneath lighter brown, at the base of the costal margin blue, near the proximal angle lighter greyish-white, with the hyaline spots as above. Hindwing radiantly silvery blue with a narrow black marginal band with 3 minute blue lunae in it in a slight expansion between the median veins and lower radial veins. 1 ♂ from Peru in the Coll. SEITZ.
- festivus.* **P. festivus** *Erichs.* (= *portulana* Plötz) (173 f) is a small, black species with some minute hyaline dots on the forewings and 2 sky-blue transverse bands across the hindwings, both of which do not reach to the costal margin. Beneath the hindwing is monotonously black, in the basal half slightly tinged blue. Guiana, Colombia.
- lucullea.* **P. lucullea** *Hew.* (173 f) is above very similar, somewhat strewn with white, the small hyaline spots in the disc more closely together; the blue bands of the hindwings are narrower and extend farther to the proximal margin. Beneath the hindwing is light blue with a narrow black marginal band, in front of it a black macular band, and in the disc 3 or 4 black spots. Brazil (Ega, Santos).
- adamantinus.* **P. adamantinus** *Mab.* (173 f) is larger than *cronion* which it approximates. Black, strewn with blue atoms, 4 small preapical hyaline spots approaching each other in two couples, below them 4 more small, little visible ones in one line towards the proximal margin and a streak-spot at the cell-end; before the fringes there is a narrow line of blue spots. Hindwing black, with a postmedian band composed of blue atoms. Beneath the forewing is similar, the costal margin as far as the cell-end blue. Hindwing blue with a broad black border growing narrower towards the anal angle. Near the costal angle a large, below it a smaller black spot. Bolivia.
- cronion.* **P. cronion** *Fldr.* (173 g) has only one broad sky-blue band on the hindwing, extending to the blue proximal margin. The forewing is brown marbled with black, strewn with white scales and 2 or 3 minute subapical dots. Beneath the proximal margin of the forewing is broadly lactean blue, the hindwing almost quite blue, only at the costal angle black with single small black marginal spots. Brazil.
- assecla.* **P. assecla** *Mab.* (= *cerealis* Plötz, nec *cerialis* Cr.) (173 g) is larger, brownish-black, with well separated, small discal spots and 6 small subapical spots. The hindwing is almost entirely blue, only at the base, costal margin and costal angle black with an indistinct median band; beneath similar, but the hindwing as far as the base blue with a fine black border which is expanded at the costal angle and proximal angle. Brazil.
- lusorius.* **P. lusorius** *Mab.* is black, with 3 small apical spots and 8 in the cell and behind it, outside with a double blue band. The hindwing with a metallic blue marginal band, near the costal angle with a black spot in it. The hindwing being blue beneath exhibits 2 bands of black spots in the disc, which are united at the proximal margin. Expanse of wings: 30 mm. Rio de Janeiro.
- cnidus.* **P. cnidus** *Plötz* (173 g) is very different: above coloured as *cerialis*, olive greyish-brown, in the basal part of the forewing and in the distal half of the hindwing with a light blue reflection, here with a dark brown middle dot and an undulate line behind it. On the forewing there are only outside of the cell 2 discal hyaline spots, before them a large, oval brown spot, behind it an undulate brown line behind which there are 4 minute subapical hyaline spots. South America (?).
- u-lucida.* **P. u-lucida** *Plötz* (173 g) is a species having remained unknown to me, presumably approximating *lugubris*. Above light brown, with antemarginal and median dark brown bands; in the median band there is a U-shaped hyaline spot distally opened, and above and below it with 2 more small hyaline spots each. Hindwing beneath in the anal half white, towards the base bluish-grey, the costal margin brown with the beginnings of 3 transverse bands. Paraguay.

7. Genus: **Ate** G. & S.

Almost the same as the preceding genus, but the posterior tibiae only exhibit 1 pair of spurs; on the hindwing the upper median vein rises somewhat nearer at the cell-angle.

- lagia.* **A. lagia** *Hew.* (173 g) is very closely allied to the following, but it has 2 or 3 more discal spots and on the hindwing beneath the blue is more uniform and extensive, the black marking reduced. Presumably only a southern form from Guiana and Brazil.

A. proxenus *G. & S.* (173 g) is above blackish-brown, behind the middle on the forewing scantily *proxenus*. dusted blue with 2 minute hyaline spots below the lower cell-angle and 2 or 3 minute subapical dots. Hindwing with a broad cyaneous marginal band. Beneath the hindwing is light blue with a brown costal margin and undulate antimarginal line, as well as 2 or 3 shortened macular bands proceeding from the costal margin. From Mexico through Central America.

A. pteras *G. & S.* (173 h) has no hyaline spots at all on the forewing, but instead of them some *pteras*. small postmedian dust-spots formed of blue scales. On the hindwing the blue marginal band is narrower and more tarnished and of a duller blue. Beneath the hindwing is almost quite blue, only at the costal margin and costal angle blackish-brown. Described according to 2 ♂♂ from Panama.

A. jovianus *Cr.* (173 h) is a large, magnificent species, black with 4 small subapical spots situate in *jovianus*. a straight line, two large discal hyaline spots, the lower being tripartite, and a blue submarginal macular band. Hindwing of a brilliant azure colour with a black costal margin and border, radiating proximally on the veins. Beneath very similar. Guatemala, Guiana to Brazil.

A. amaryllis *Stgr.* (173 h) differs by the much larger oval discal spot and enlarged subapical spots of *amaryllis*. the forewings. Guatemala, Panama, Colombia, Brazil.

A. fabricii *Ky.* (= *jovianus* *F.* nec *Cr.*) (173 h) differs by a large, white discal spot in the blue of *fabricii*. the hindwing and larger discal spots of the forewing. Colombia, Brazil, Bolivia.

A. suppar *sp. nov.* (173 h) entirely resembles *jovianus* above; the discal hyaline spots of the forewing *suppar*. are somewhat more oblique, on the hindwing the black marginal band is broader and proximally not faded as in *jovianus*, but sharply defined. As in *fabricii* there is in the blue disc a white spot divided into five parts by the black veins. Eastern Colombia (Medina) in the Coll. FASSL.

A. lancea *Hew.* (= *tertullianus* *F.*) (173 h) resembles the preceding, but the subapical spots are *lancea*. absent; the discal spot is much larger, and on the hindwing in the cell and behind it there is a white diaphanous longitudinal spot growing more roundish in the ♂. Hindhead and palpi orange-yellow. Brazil: Minas-Geraes, Sao Paulo, common near Santos.

A. lerina *Hew.* (173 i) has a large, quadripartite discal spot on the forewing, in the middle of the *lerina*. hindwing a round blue spot not sharply defined. Beneath the hindwing is blue with a black border, proximal margin and veins. Guiana, Brazil.

A. aequatoria *Mab.* is still larger than *jovianus*, jet-black, with three subapical dots situate in *aequatoria*. a triangle, below them two more and still farther down three larger ones; in the cell and at the costal margin there are 2 longish hyaline spots, below them two more. The hindwing exhibits 2 narrow blue bands connected at the costal margin, separated in the disc. Beneath the proximal margin of the forewing is broad whitish, the hindwing quite blue, except a black spot at the costal angle. From Ecuador.

8. Genus: **Paches** *G. & S.*

It is likewise very closely allied to the two preceding genera, the antennal club is somewhat longer, the 3rd palpal joint longer. The posterior tibiae exhibit beside 2 pair of spurs in the ♂ a long hair-pencil. Half a dozen of sexually dimorphous species with mostly blue ♂♂.

P. loxus *Dbl. & Hew.* (173 i) is in the ♂ above of a lustrous deep ultramarine, with a black border *loxus*. and spot at the cell-end and costal margin. Beneath black with 3 indistinct darker transverse bands. The ♀ is blackish-brown, with 3 small subapical dots and a slate-blue band of scales in the middle. Mexico to Panama.

P. gladius *Btlr.* (173 i). Instead of the black costal marginal spot there is here a median band more *gladius*. or less distinctly noticeable also on the hindwing. Brazil. Probably only the southern form of *loxus*.

P. polla *Mab.* (173 i) has almost black forewings with 2 or 3 small subapical hyaline spots, near *polla*. the proximal angle with some blue scales. The hindwings are lustrous blue, with an indistinct, lighter greyish-blue median band and mostly another one behind it. Beneath scantily strewn with a light tint. Mexico to Costa Rica.

P. narycus *Mab.* (173 i) is above in the disc of the hindwing deep blue. Forewing almost black *narycus*. with a row of whitish-blue spots which is interrupted below the apex, behind it a grey band with a dull silvery lustre, passing over to the hindwing and often indistinct towards the margin; in the cell of the forewing there is a longitudinal row of some dots. Beneath quite blackish-brown. Described from Ecuador, before me also from Peru (Pozuzo, Huancabamba).

subalbatus. **P. subalbatus** Plötz (= subornatus Mab., zonula Mab.) (174 a). Hitherto only the ♀ seems to be known; above blackish-brown with a median band formed of blue scattered scales on both wings and 3 small, white subapical dots on the forewing. Beneath the anal half of the hindwing is white with a blackish antemarginal line; the bordering towards the base is brightened up in a bluish grey and tinged brownish-red. Panama, Venezuela, Colombia, Brazil.

geometrinus. **P. geometrinus** Fldr. (= hadina Btlr., corbinianus Plötz) (174 a) has brown wings being lighter towards the margin, traversed by 2 darker transverse bands bordered by a lighter colour and parallel to the distal margin. Beneath lighter, on the forewing strewn with a reddish yellow and with a reddish-yellow discal macula, the hindwing scantily strewn with whitish, and with 2 whitish transverse lines. Panama to Southern Brazil.

phalaena. **P. phalaena** Mab. (*Stgr.* i. 1.) is apparently very closely allied to *geometrinus*. Yellowish brown with black transverse bands across both wings; the base brownish, behind it a black, distally bent band across the cell-end; on the hindwing the band is narrower; a proximally curved postmedian band terminates on the fore- and hindwing at the proximal margin with a thick black spot; at the margin another broad band. The under surface is greyish-brown with an ochreous spot in the middle, before it a grey band spotted white at the proximal margin, behind it a grey band being ochreous-yellow below the cell and terminating in a grey spot bordered with yellow. Hindwing bluish greyish-white, at the base brown with a grey median band and a blackish grey border. Bolivia.

limaea. **P. limaea** Hew. (= jablesa Btlr., caeruleus Plötz) (174 a). Forewing similar as in *subalbatus*, but the hindwing with a broad blue marginal band. Beneath the hindwing is extensively blue with a more or less spotted blackish-brown costal margin, often there is only one spot at the costal angle. Brazil (Amazon).

9. Genus: **Spioniades** Hbn.

Antennal club moderately thick with a short, bent apex; the 3rd joint of the porrect palpi is hidden. The apex of the forewing somewhat stunted. The costal fold is absent. Hindwing prolonged. The posterior tibiae with 2 pair of spurs and a hair-pencil.

artemides. **Sp. artemides** Cr. (174 a). Forewing blackish-brown with white scales strewn in the shape of a band, several minute discal and subapical hyaline dots. Hindwing in the anal half white, in the ♂ tinted somewhat brownish with a more or less distinct marginal band before the fringes. From Panama through Guiana to Southern Brazil.

abbreviatus. **Sp. abbreviatus** Mab. (174 a) is somewhat larger, the forewing shorter and broader with larger hyaline spots, the hindwing not so much prolonged, the white anal part of the hindwing reduced, the marginal band divided into spots, the lowest more distantly remote from the proximal angle than in the preceding. Nicaragua, Costa Rica, Panama, Colombia to Bolivia.

10. Genus: **Nerula** Mab.

In the characters it entirely corresponds to the genus *Cogia* of the preceding group, but the cell of the forewing is shorter than $\frac{2}{3}$ of the length of the costal margin. Only one species:

fibrena. **N. fibrena** Hew. (= nautes Mab.) (177 e) is above dark brown, the forewing with 11 hyaline dots: one at the costal margin, 2 in the cell, and one below it of the shape of the number 2; farther towards the margin 3 and an isolated one above it and 3 subapical ones. The hindwing exhibits at the base a tuft of yellowish-red hair, the anal angle is broadly white, parted by a brown band. Beneath the same, only of a paler tint; hindwing entirely white, costal margin, 2 spots below it near the base, an irregular transverse band and a spot at the anal angle yellowish reddish-brown. Expanse of wings: $1\frac{4}{10}$ inches. Amazon (Tonantins).

11. Genus: **Eracon** G. & S.

In its anatomical marks it is very closely allied to the genus *Pellicia*, but the posterior tibiae in the ♂ exhibit a long hair-pencil, and the prolonged hindwing shows above at the base of the costal margin a hair-tuft. The forewing exhibits a black spot in the cell as in *Cyclosaemia*.

biternata. **E. biternata** Mab. is dark brown with 3 darker transverse bands, in the disc of the forewing with a large black spot with two white hyaline dots in it and one above it; 3 minute, subapical, white hyaline spots in a triangle. Beneath lighter and more reddish brown. The body beneath is whitish. Panama (Chiriqui).

E. bufonia *Mschlr.* (174 b) has almost the wing-contours of *Arteurotia tractipennis* (172 h); above *bufonia*. brown, in the larger basal half dusted violettish-grey with a large, black, quadrangular discal spot, from where an extinct band extends to the proximal margin, with a second transverse, postmedian band. Hindwing similarly marked. Under surface lighter brown, at the proximal angle of the forewing and in the middle of the hindwing with quadrangular, large, yellow spots, behind them with an irregular row of smaller spots and similar ones at the costal margin, proximal margin and anal angle. Colombia.

E. inops *Mab.* is above reddish-brown with 4 bands of black spots; beneath more reddish-grey, *inops*. the lines extinct. Patria unknown.

12. Genus: **Gorgopas** *G. & S.*

From the closely allied following genus *Pellicia* separated by the presence of a costal fold and the absence of the hair-pencil on the posterior tibiae.

G. viridiceps *Btlr.* (174 b) is deep dark brown, before the distal margin lighter in the shape of *viridiceps*. spots, with 3 small, white, subapical spots. Head, collar, anterior half of the shoulder-covers and palpi above metallic green. From Nicaragua to Peru and Brazil.

G. hybridus *Mab.* looks like a *Cyclosaemia* (p. 894) with a green head: light brown, forewing with *hybridus*. a blackish marginal band, separated from the margin by a row of small lighter spots, in front of it a dark band with 3 subapical hyaline dots; in the cell there is a black spot with 2 white dots in it, the head and thorax metallic green. Expanse of wings: 28 mm. Brazil.

G. chlorocephala *Latr.* (174 b) is of a lighter ground-colour than *viridiceps*, and metallic green scales *chlorocephala*. are also at the bases of the wings. Guiana.

13. Genus: **Pellicia** *H.-Schäff.*

One of the most difficult groups to describe. GODMAN says that the attempt of ascertaining the species according to descriptions is hopeless. More than 2 dozens of almost uni-coloured blackish-brown species have been described. The forewing is rather pointed, the distal margin convex, no costal fold. The hindwing is analwards somewhat prolonged. The posterior tibiae are provided with hairy fringes and 2 pair of spurs, without a hair-pencil. The ♂♂ besides exhibit a long hair-tuft at the base of the costal margin on the hindwing; the subcostal vein mostly shows a slight swelling.

P. ephora *H.-Schäff.* (= *tiphys* *G. & S.*) (174 b) is one of the most common Hesperids in the whole *ephora*. of Central and South America. Deep dark brown with 3 still darker, faded transverse bands and 3 white subapical dots situate in a triangle, the marginal band being separated from the median bands. The under surface is coloured lighter, the ♀ also above. Widely distributed from Mexico to Colombia and Guiana.

P. bessus *Mschlr.* (= *sordidulus* *Mab.*) (174 b) is extremely similar, darker, the hindwings much rounder; *bessus*. with differently shaped genitals. Surinam.

P. macareus *H.-Schäff.* (174 b, c) is likewise scarcely distinguishable from *ephora* in its exterior, but *macareus*. the shape of the wings is much rounder, particularly of the hindwings, and the hair-pencil at the costal margin of the hindwing is considerably shorter. It occurs from Mexico through the whole of Central America to the Amazon.

P. criton *Mab.* is very closely allied to *ephora* (174 b), but smaller and discernible by the under surface. *criton*. The 3 white subapical dots are situate more in a line; the black anteterminal band is indistinctly spot-shaped. Beneath on the forewing the costal margin and apex are grey, the hindwing pinkish-grey, only at the base and costal margin blackish; before the fringes extends a narrow, interrupted band, through the middle a broader one. Bolivia.

P. bipuncta *Schs.* (174 c) is distinguished from *ephora* (174 b) by only 2 small subapical hyaline *bipuncta*. dots and less undulate transverse bands which are more broadly fused with each other. Expanse of wings: 29 mm. Brazil (Novo Friburgo).

P. nycineme *Btlr.* above entirely resembles *macareus* (174 b, c); it is discernible by the hindwing *nycineme*. beneath, where the spots of the median band are tinted light towards the base. From Nicaragua to Colombia and the Amazon.

P. bromias *G. & S.* (174 c) is a somewhat smaller species with rather distinctly prominent bands; *bromias*. the most characteristic mark is the fusion of the submarginal and median bands below the cell, so that a Y-shaped, dark marking is created. Common in Mexico and southward to Panama.

- costimacula*. **P. costimacula** H.-Schüff. (174c) is more easily recognizable by the wings exhibiting violettish-grey costal and basal halves; in this ground the beginnings of the 3 dark brown bands are distinctly prominent, the two interior ones almost exactly rectangular to the costal margin, the distal one more oblique towards the margin. This species and the following are without the small subapical spots. From Mexico down to Peru and Brazil, common.
- violacea*. **P. violacea** Mab. Forewing brown, glazed in a violettish blue, thereon three brown or ferruginous bands, the middle band only forming a spot at the cell-end. Hindwing rusty black with 2 scarcely noticeable violet bands, at the costal margin lighter ferruginous. Beneath the forewing is rusty-black with 2 scarcely visible violet bands, at the costal margin lighter ferruginous. Beneath the forewing is rusty black, at the costal margin and apex dusted ash-blue like the proximal margin. Hindwing in the basal half rusty black, outside light ash-blue, in it 2 faint, brown bands. Expanse of wings: 29 mm. Patria unknown.
- dimidiata*. **P. dimidiata** H.-Schüff. (= *didia* Mschlr., *corinna* Plötz, *nivonicus* Plötz, *bilinea* Mab.) (174c) is marked the same as *costimacula*, but somewhat smaller, with broader, rounder wings and entirely without the purple-grey suffusion of the costal parts of the wings. The anal part of the hindwing is prolonged, but more in the shape of a broadly rounded lobe. Likewise most common beginning from Mexico, but the species seems not to go so far to the south, reaching its southern extremity at Guiana.
- meno*. **P. meno** Mab. (174c) has a somewhat longer anal part of the hindwing than the preceding; this part being beneath whitish with a large, dark brown spot in it; in the disc there are besides 2 whitish spots, and the proximal margin of the forewing is light, too. The costal-marginal part of the forewing is above suffused with lilac-grey as in *costimacula*. This little species has apparently been hitherto only found in Panama.
- vecina*. **P. vecina** Schs. (174d) very much resembles *costimacula* (174c) above, but the hindwing beneath is very different. Forewing dark greyish-brown with the darker brown bands as there. The hindwing is lighter at the costal and proximal margins. Beneath the forewing is dark brown, the proximal margin very light. The hindwing is dark brown in the costal half, in the anal half whitish grey; in the middle, behind it and before the margin traces of darker lines. Expanse of wings: 32 mm. Petropolis.
- pericles*. **P. pericles** Mab. (*Stgr.* i. l.) (174d) is likewise not dissimilar; above deep velvety-black before the margin, with a lighter reflecting violet macular band, which grows broader and still lighter towards the apex; the beginnings of 2 similarly coloured bands commence at the costal margin before the cell-end and before the middle of the cell and extend almost to the median. Hindwing similar; beneath almost uni-coloured blackish-brown, the proximal margin of the forewing lighter reddish. Bolivia.
- licisca*. **P. licisca** Plötz (= *thystes* G. & S.) (174d) is recognizable by the entirely rounded hindwing without an extended anal part. The colour of the wings is very dark, so that the bands are scarcely prominent, only on the lighter under surface and in the ♀ they are more distinct. Found from Mexico to Panama.
- capitans*. **P. capitans** Schs. externally resembles *G. viridiceps* (174b) by its brilliant metallic-green head and collar. The wings are dark velvety-brown in the basal halves, distally somewhat lighter with a darker shade at the distal margin. The forewing shows 3 subapical hyaline dots in a darker oblique shade, the hindwing a narrow, antemarginal nebulous band. Beneath lighter brown with traces of darker lines. Expanse of wings: 27 mm. Venezuela (Aroa).
- polyctor*. **P. polyctor** Prittw. (= *ithrana* Btlr.) (174d) is quite differently coloured and marked: white with a dark brown basal and distal third, in the latter 3 subapical hyaline spots, farther below 2 larger, square hyaline spots scarcely noticeable in the white ground; in the discal area besides some brownish dentate lines; hindwing in the costal part almost entirely white. Very common from Mexico to Colombia and Southern Brazil.
- castolus*. **P. castolus** Hew. (174e) by its under surface is most closely allied to *vecina* (174d), but above it is almost uni-coloured blackish-brown, on both wings quite indistinctly spotted grey; the forewing shows 3 subapical hyaline dots, situate in a grey spot beneath. The anal half of the hindwing is whitish-grey, undulated blackish-brown. Described from Brazil.
- zamia*. **P. zamia** Plötz (174d). Above monotonously blackish-brown, beneath the forewing is lighter in the proximal-marginal area; the hindwing is tinted ferruginous and the anal half powdered greyish-white, the margin itself, however, remaining dark and 2 dark stripes in the disc penetrating the lighter area. South America.
- theon*. **P. theon** Plötz (174d) entirely resembles *zamia*, but it is larger and the upper surface is not so deep blackish-brown, so that a curved stripe before the marginal area on all the wings, a nebulous spot at the cell-end and another nebulous stripe at the end of the basal third are distinctly standing out. Beneath the anal parts of all the wings are lighter, of a dim whitish, and in this light part the nebulous stripes of the uppersurface show through as a chain of dark spots. From South America (the exact patria is not stated in PLÖTZ' table).
- demetrius*. **P. demetrius** (174c) is above uni-coloured dark brown with 2 dark ante- and postmedian transverse lines on the forewing. Beneath the apical part of the forewing and the greater part of the disc of the hindwing is suffused with a bluish grey, the powdered patches being traversed by dark brown lines of the ground-colour. Brazil.

P. albangula *H.-Schäff.* (174 e) is a charming, tiny insect, in which the apex of the forewing is *albangula*, ensiformly extended and the margin of the hindwing projects in the middle like a tooth. Above purple-brown with deep dark transverse bands and ferruginous spots in a row before the margin of the forewing and in a treble row above the anal marginal part. Forewing with the 3 subapical, most minute spots and a fourth in the cell-end area. Beneath in the costal and basal parts ferruginous, dusted over and speckled with black; at the anal angle on all the wings lighter yellowish-white with ferruginous markings. It is reported to originate from Rio de Janeiro.

P. meris *Plötz* (174 e) differs only little from the preceding, above black with 2 deeper black transverse *meris*, bands and 3 small white subapical dots. Beneath somewhat duller, tinted more olive. Hindwing extended rather long. Colombia.

14. Genus: **Pyrdalus** *Mab.*

Distinguished from *Pellicia* by the longer, rectangularly bent antennal club, the presence of a costal fold in the ♂, and a longer 3rd palpal joint. Here the hindwing also shows a hair-pencil at the base of the costal margin and the fringed posterior tibiae show 2 pair of spurs. Only one species:

P. corbulo *Cr.* (174 e) looks like a large *Pellicia*, deep blackish-brown with faded black transverse *corbulo*, bands and 3 minute subapical spots. In the ♂ the costal margin of the hindwing is of a light reddish-brown, from which the dark pencil stands out distinctly. Beneath lighter, otherwise marked the same, at the proximal margin of the hindwing and on the ventrum bluish-grey. From Surinam.

15. Genus: **Mycteris** *Mab.*

Likewise extremely approaching *Pellicia* and, as there, with the hair-pencil of the hindwing and the swelling of the subcostal veins. The palpi are much longer, rostriform, and have a rather pointed, straightly porrect terminal joint. On the hindwing the subcostal vein rises much nearer at the base. No costal fold. 4 species are known:

M. caerulea *Mab.* (174 f). Above almost uni-coloured brownish-black, particularly in the ♀ with *caerulea*, traces of darker bands, at the costal margin of the hindwing somewhat lighter. Beneath lighter, the proximal margin of the forewing lilac-grey, the proximal half of the hindwing light greyish-blue, in the ♀ darker. Guatemala to Colombia.

M. tyana *Plötz* (174 f) is similar, somewhat smaller and with a lighter, violettish- or purple-grey *tyana*, costal-marginal area of the forewing, in which the beginnings of darker bands are to be noticed in a similar way as in *Pellicia costimacula* (174 e). Beneath the proximal half of the hindwing is violettish-grey or bluish-grey, both wings show traces of dark, brown bands. Brazil (Sao Paulo).

M. cambyses *Hew.* (174 f) is allied to *caerulea*. Upper surface deep blackish-brown, both wings *cambyses*, with a submarginal row of grey spots, towards the apex larger, dying away analwards; the forewing exhibits an indistinct, short grey band from the middle of the costal margin, the hindwing a similar one in the middle. Beneath dark brown, the apex paler, the proximal margin grey; hindwing reddish-brown, the costal margin and 2 indistinct transverse bands darker brown. Bolivia.

M. crispus *Plötz* (174 f) is above deep purple-brown with a violet shine, with a darkened margin *crispus*, and 3 scarcely visible darker transverse bands similar to the *Pellicia*-species; between the distal band and the margin the ground-colour appears lighter. The under surface is also very dark, without any marking, the inner-marginal area of the forewing brownish, the proximal half of the hindwing lighter, more violettish-grey, with slightly darker veins. Venezuela.

16. Genus: **Nisoniades** *Hbn.*

Antennal club moderately thick, the pointed end uniformly bent; the 3rd palpal joint shortly porrect. Costal fold absent; shape of wings rather narrow, the cell of the forewing narrow, too. Veins scarcely deviating from *Pellicia*; hindwing rounded off. Posterior tibiae fringed with 2 pair of spurs.

N. bromius *Stoll* (= *fissimacula* *Mab.*) (174 f). Above dark brown, at the cell-end with a thick, *bromius*, black spot with two white pupils; before the apex there are 3 small subapical dots, 2 more between the median and lower radial veins. Beneath much lighter olive-brown, at the anal part of the hindwing more bluish-grey with the spots as above. From Surinam. — The larva, according to *STOLL*, living on *Solanum spinosum*, is green with a black head and an interrupted black dorsal line and changes into a brownish pupa on the upper surface of the leaf being somewhat drawn together by few threads.

N. pelarge *G. & S.* (174 f, g) is perhaps of the same species, above with somewhat more distinct *pelarge*, bands; beneath the hindwing is much more extensively blue or lilac-grey, towards the costal margin with 3 darker bands. Nicaragua.

17. Genus: **Cyclosaemia** Mab.

Scarcely to be separated from *Nisoniades*. The forewing is comparatively a little broader, the hindwing still rounder, the terminal joint of the palpi longer. Quite a number of mostly rather similar forms.

- herennius*. **C. herennius** Cr. (174 g). Above deep blackish-brown, in the basal half almost black, at the cell-end with a large, black spot twice pupilled white, and behind it besides 2 black bands. Hindwing the same, though without the cell-spot. Beneath the forewing is lighter brown, at the proximal margin light brownish; the hindwing is bluish-grey with 3 black transverse bands, the proximal one of which bifurcates in the shape of a Y near the costal margin. South America.
- caecus*. **C. caecus** Plötz (174 g) is somewhat similar, discernible particularly by the non-pupilled discal spot on the forewing. The colour is a lighter, duller brown, the bands are narrower. Beneath the hindwing is lighter lilac-grey, the bands pale brownish, the proximal one not forked. Patria unknown.
- morvus*. **C. morvus** Plötz (174 g) is very much larger, it has only a singly pupilled cell-spot, only one curved band behind it, in which there are 3 white subapical dots below the costal margin; hindwing at the distal margin somewhat lighter with small darker spots in the spaces between the veins. Beneath the proximal third of the hindwing is bluish, at the proximal margin almost entirely white. Brazil.
- monophthalma*. **C. monophthalma** Plötz (= *trigonilla* Schs.) (174 g) is smaller, above similar to *morvus*, but much lighter brown; the singly pupilled cell-spot is situate in a yellowish ring; the subapical spots are absent. Beneath the hindwing is monotonously light brown with 2 fine brown transverse bands, and in front of a marginal line with a row of dark triangular spots. Brazil.
- phidyle*. **C. phidyle** G. & S. (174 g) like *caecus*, has a non-pupilled black cell-spot, but it is much larger; the brown wings are lighter in the disc, 3 subapical dots in one line are encircled by black. The species is easily recognized by the light reddish-yellow apical half of the forewing beneath, in which the cell-spot is entirely absent. It seems hitherto only to be known from Panama.
- myris*. **C. myris** Mab. is just as large as *phidyle*; the apex of the forewing is prolonged. Above reddish-brown, without apical dots, with an indistinct blackish postdiscal band, which is angled on the upper radial vein and runs obliquely to the proximal margin; in the large black cell-spot there is a white dot, from where a brown shade extends to the proximal margin. The hindwing shows traces of 2 darker postmedian nebulous bands. Beneath monotonously yellowish-brown, the cell-spot indicated by reddish-brown, the bands are more distinct than above. It is perhaps no *Cyclosaemia*. Described according to 1 ♀ from Sa. Catharina.
- anastomosis*. **C. anastomosis** Mab. (174 h) is a more common species, above brown with 2 darker transverse bands and the cell-spot encircled by yellowish, with 2 white dots there in. Beneath lighter, the bands narrower, on the hindwing spot-shaped; the proximal margin of the hindwing is bluish-grey. Widely distributed from Mexico to Brazil.
- binoculus*. **C. binoculus** Mschlr. (= *earina* Hew.) (174 h) differs by more spot-shaped transverse bands, the proximal one being only indicated on the forewing, the margin darkened. Beneath the bluish-grey colour is absent at the proximal margin of the hindwing, instead of which there is a large black spot at the anal angle. Pará.
- gratiosa*. **C. gratiosa** Mab. resembles *binoculus*. Forewing above yellowish brown with a broad, brown marginal band and a curved postdiscal band; the cell-spot as in the two preceding encircled by yellow with 2 white dots, the basal area darker brown. Hindwing with 3 bent bands. Beneath light brown, the bands more distinct, the forewing at the proximal margin light ash-grey. Hindwing at the costal and distal margins light grey, from the middle to the proximal angle bluish-white; the bands on the brown ground distinctly defined, on the white ground dying away except the marginal band remaining dark. Panama (Chiriquí).
- jacobus*. **C. jacobus** Plötz (174 h) differs by the cell-spot above exhibiting 3 white dots and by 3 subapical hyaline dots. Beneath the hindwing is quite light blue with an irregular black border. From Rio.
- paullinus*. **C. paullinus** Cr. (174 h) is above quite similar to *gratiosa*, but it has a white subapical dot; beneath the whitish parts are coloured ochreous reddish-yellow. Guiana.
- metallica*. **C. metallica** Mab. is easily recognized by the metallic green head and thorax; above coppery brown, the forewing with 3 white subapical dots encircled by black; an antemarginal, a postdiscal and a discal brown band, the two distal ones spotted, the proximal one extending to the proximal margin as the continuation of the large, black, twice white-pupilled cell-spot. The hindwing shows 3 bands of brown spots. The under surface is light grey, almost white, the bands pale dirty brown. Guiana, Brazil.
- diophthalma*. **C. diophthalma** Plötz (174 h) in its colour and marking resembles rather much *monophthalma*, but the cell-spot itself is divided into 2 separate spots beneath each other, and the anteterminal macular band

bifurcates towards the costal margin like a Y, the hindwing shows at the cell-end a third transverse band reaching neither the costal margin nor the proximal margin. Beneath the hindwing is extensively whitish, towards the base and at the proximal margin dusted with blue with a dark brown marginal macular band. Patria unknown.

C. elelea Hew. is most closely allied to *jacobus* (174 h), distinguished by 2 postdiscal transverse bands, *elelea*, a third, shortened band extends from the oval, twice white-pupilled discal spot to the proximal margin; inwardly the discal spot is bordered lighter. Beneath the brown forewing is lighter at the proximal margin, at the base blue; the hindwing is entirely sky-blue, only at the apex there is a black spot and the fringes are dark brown. Expanse of wings: 1½ inches. Cayenne.

C. lathaea Hew. (174 i) stands between *herennius* and *jacobus* (174 h). Above reddish-brown, marked *lathaea*, as *herennius*. Beneath the forewing is also a little tinted blue at the base; the hindwing is pale blue only as far as the distal transverse band; in the place of the proximal transverse band there is a row of grey spots. Described from Bolivia.

C. falisca Hew. is most closely allied to *paullinus* (174 h), distinguished by 3 small subapical dots *falisca*, and a fourth farther below; an anteterminal, dark macular band is situate between the postdiscal band and marginal band. Beneath the forewing shows an ochreous-yellow spot near the apex. Hindwing yellow with some costal-marginal spots, a brown, indistinct, postdiscal transverse band and a brown margin, in front of which is a row of indistinct spots, and at the anal angle a black spot. Cayenne.

C. parus Mab. is very closely allied to *falisca*, distinguished by the absence of all the transverse bands, *parus*, only the margin is darkened by a violet lustre, with a white subapical dot. The black discal spot shows only one white pupil. Hindwing with a broader dark margin. Beneath the forewing is dull black, at the proximal angle with 2 yellow spots. Hindwing blackish with 3 yellow bands: a narrow one at the margin, before it a broader one proximally dentate, and the discal band extending from the proximal margin only to the middle. From Porto Cabello.

C. albata Mab. (174 i) deviates very much from the other species by the wings showing an almost *albata*, white discal area. The basal and marginal areas are yellowish-brown, the latter towards the distal margin darkened; at the cell-end there are, as in *diophthalma*, 2 separate, white-pupilled spots. The hindwing shows at the margin 3 black transverse bands. Colombia, Bolivia, Peru.

18. Genus: **Anastrus** Hbn.

The antennae have a long, slender, gradually thickened club terminating equably bent into the thin point. The short, obtuse terminal joint of the palpi is perfect. Forewing with a costal fold, the apex somewhat produced, the distal margin convex; the cell long and narrow. The anal angle of the hindwing somewhat produced. Posterior tibiae with 2 pair of spurs and a long hair-tuft at the proximal end. The genus is very closely allied to the following genus and so far contains 6 species.

A. obscurus Hbn. (174 i) is above deep blackish-brown, at the costal margin, the distal margin of *obscurus*, both wings and a discal band of the hindwing with a violet reflection; the ♀ is lighter brown with faintly visible darker bands and a discal spot of the forewing. Under surface much lighter and more reddish brown, with 2 narrow transverse bands removed rather far towards the margin. Widely distributed in South America.

A. neaeris Mschlr. (= *obscurus* Btlr. nec Hbn.) (174 i) is above very similar, the costal margin not *neaeris*, so extensively reflecting violet, this colour being more confined to a subapical costal-marginal spot; easily discernible by the whitish greyish-blue anal part of the hindwing beneath. Widely distributed from Mexico to Colombia, Venezuela.

A. petius Mschlr. (174 i) is likewise similar, above deep purple-black, the forewing exhibits towards *petius*, the proximal angle near the margin, the hindwing along the whole distal margin bluish-grey dusting; here also a spot in the disc is coloured the same. Beneath almost uni-coloured reddish-brown. From Surinam.

A. austera Prittw. One ♀ without the patria being stated, but described by v. PRITTWITZ with a *austera*, great number of Brazilian lepidoptera from Rio de Janeiro, according to the denomination by HERRICH-SCHAEFFER, has the size and shape of *Eantis thraso* (176 b), but above the colour turns more bluish. The apex of the forewing is obtuse; the wings above without lighter spots. At the costal margin, in front of the distal margin and at the proximal margin dispersed, light bluish-grey atoms; the distal margins of both wings are without this dusting. Under surface dark cinnamon-brown. Forewing scantily, hindwing almost entirely covered with small light blue scales, nearly of the colouring of *Lycæna corydon*. Head, abdomen and antennae dark brown; beneath the whole insect is silvery grey.

A. subchalybeus Mab. is above violescent black with a bluish-violet reflection; the forewing shows *subchalybeus*, 2 broad black bands growing broader and anastomosing in the disc, and a third at the base, besides a black

marginal band which is broader on the hindwing; the discal band is angled on the hindwing. The under surface is lighter, more brownish, with the same, though fainter markings. Expanse of wings: 37 mm. Manaos.

obliqua. **A. obliqua** Plötz (174 i) is very different: above purple blackish-brown, with 3 broad, oblique transverse bands, the middle one of which extends on the forewing from the middle of the costal margin to the proximal angle, the short distal one from the distal fourth of the costal margin to the upper third of the distal margin, which is darkened. Beneath uni-coloured light reddish-brown. Brazil, Colombia.

19. Genus: **Gorgophone** *G. n. S.*

Different by the absence of the costal fold and of the hair-pencil on the posterior tibiae. Only 1 species:

meliboea. **G. meliboea** *G. & S.* (175 a) resembles rather much *Anastr. neaeris* (174 c), but it is larger, deep purple-black, with lighter lustrous violet antemarginal bands, beneath the same as *neaeris*. Described from Panama.

patens. **G. patens** Plötz (175 a) may belong hereto. Above as *Echel. varius*, but only with one distinct discal band; hindwing at the proximal margin narrowly ochreous-yellow. Beneath reddish-brown, in the disc particularly of the hindwing lighter, tinged violet, the hindwing with a broad, reddish-brown, postdiscal transverse band. Described from Rio.

20. Genus: **Echelatus** *G. n. S.*

Likewise very closely allied to *Anastrus*; distinguished by the absence of the pencil at the posterior tibiae, whereas the costal fold is mostly very well developed. The forewing is generally somewhat longer, narrower, with a less truncate apex, the hindwing comparatively smaller.

varius. **E. varius** *Mab.* (175 a, b) is a common species, distributed from Mexico through the whole of Central America to Colombia and Venezuela. Above dark brown, towards the margin darker with 2 broad, faded, darker transverse bands. Beneath lighter, reddish-brown, on the hindwing in the anal part light bluish-grey, with 3 darker transverse bands. Costal fold well developed.

eugramma. **E. eugramma** *Mab.* differs from *varius* by 3 small subapical dots and 2 more below them, all being encircled by black; the transverse bands are black and distinct. The hindwing is in the anal half of a bright blue, otherwise ferruginous with 3 dark transverse bands therein. From Panama (Chiriqui).

robigus. **E. robigus** Plötz (= *luctuosus* *G. & S.*) (175 a) is above the same as *varius*, beneath on the hindwing the anal half is not bluish-white, but of the same colour with the rest of the wing. If the genitals were not constantly different from *varius*, we might think it to be a local form, since the species is known from Western Mexico, where *varius* is absent, besides from Southern Brazil and Colombia.

sempiternus. **E. sempiternus** *Btlr. & Drc.* (175 a) has above a somewhat lighter ground-colour with more distinct transverse bands and a large, black, quadrangular cell-macula; the hindwings are also distinctly marked. Beneath scarcely different from *varius*. Separated by the costal fold being almost absent in the ♂. Common and widely distributed from Mexico to the Amazon.

polyaenus. **E. polyaenus** *Mab.* resembles *platypterus* in its shape, the forewing with a more pointed apex, brownish-red with 2 discal bands, one near the base, the other extending through the disc and bifurcating at the cell-end, sending one branch to the costa; at the margin a more deeply coloured, badly demarcated band. In the hindwing similar marking, the space between the two bands rather genuinely reddish-brown. Colombia.

platypterus. **E. platypterus** *Mab.* This imago unknown to us is compared by MABILLE with *Achlyodes lalandii* *Latr.* (Encycl. Méthod. 9, p. 761, Nr. 95 Note) which, however, is not at all stated in the Hesperid catalogue by MABILLE himself. The patria is known neither of this nor of *platyptera*; it is described to be of a shape similar to *lalandii*, blackish-brown, with 2 badly defined bands on the forewing; the first very broad, occupying the whole cell and dissolved in the basal brown; the second very broad; at the margin a broad band.

diversus. **E. diversus** *Mab.* approaches *luctuosus*; smaller with distinct, black macular bands, the wings in a certain exposure to light with a violet reflection. Beneath brown with an ochreous-yellow apical spot, also the proximal margin of the same colour; hindwing ochreous-red with 3 distinct macular bands. Colombia, Brazil.

simplicior. **E. simplicior** Plötz (= ♀ *alburnea* Plötz) (175 b) resembles *sempiternus* above by the distinct band-marking and the cell-spot, but beneath the hindwing is quite brown as in *robigus*, without the blue anal part; the transverse bands extend almost to the proximal margin. Brazil, Paraguay.

E. tolimus Plötz (175 b) is marked above as *Gorg. patens* (175 a) with but one dark median band, *tolimus*, the margin being very much darkened. Beneath likewise similar, but the anal half of the hindwing is blue. The postmedian transverse band is here very distinct. From Colombia. The species may be better inserted in *Gorgophone*.

21. Genus: **Grais** G. & S.

Is very closely allied to *Anastrus*, chiefly distinguished by its longer and narrower cell of the forewing; costal fold and hair-pencils on the posterior tibiae are absent.

G. stigmaticus Mab. (= *fumosus* Plötz) (175 b). A common, widely distributed, large species. Above *stigmaticus*, brown with 2 spotted darker transverse bands, the proximal one being shortened and provided with 2 or 3 minute, white, subapical hyaline dots. Beneath somewhat lighter, otherwise marked the same. From Mexico to Panama, to Colombia and Southern Brazil, occurring also in Jamaica.

G. choricus Schs. is just as large, dark brown, with a violet lustre, at the distal margin darker, the *choricus*, transverse bands somewhat spotted; 3 small, subapical, hyaline dots. Beneath separated by the anal part of the hindwing being scaled lilac-grey, the distal brown macular band being more distinctly prominent. From Mexico (Paso de San Juan).

22. Genus: **Mylon** G. & S.

The third joint of the horizontally porrect palpi is very short. The forewings are broad, at the apex somewhat stunted. The posterior tibiae exhibit a hair-pencil and 2 pair of spurs.

M. lassia Hew. (175 c) is above whitish, dusted grey, in the basal and marginal thirds of the fore- *lassia*, wing, and more narrowly at the margin of the hindwing densely dusted with brown and very much like *Eudamidas melander* from which it is easily separated by 4 small, hyaline, subapical spots and the long hair-pencils of the posterior tibiae. Very common and widely distributed from Mexico to Colombia and Bolivia.

M. pulcherius Fldr. (175 c) is very similar, larger, the discal area of the hindwing more uniformly *pulcherius*, dusted brown, faintly contrasting with the basal and marginal areas; the dark marginal area of the hindwing broader. Mexico to Colombia and Brazil.

M. pelopidas F. Forewing above dark ash-grey with a dark brown discal line. Hindwing ash-grey. *pelopidas*. Body dark brown, antennae black. Hindwing with darker marginal dots. Under surface ash-grey. — This very short description which fits to quite a number of species mentions as patria: „in Indiis“, which probably means the West Indies formerly constituted by great parts of tropical America.

23. Genus: **Eudamidas** G. & S.

Different from *Mylon* merely by the absence of the hair-pencil of the posterior tibiae.

E. melander Cr. (175 c) is a well-known, very common species with greyish-white wings dusted *melander*, brown in the basal and marginal areas, with torn, dark macular bands; easily discernible from the very similar *Mylon lassia* by the absence of the small hyaline spots and of the hair-pencils. From Mexico to Paraguay. — From Peru f. **obscurior** Schs. was described; above darker and browner, forewing without a discal spot, the subterminal shade darker and not dentate.

E. ozema Btlr. (175 c) is similar, smaller, paler, more thinly scaled, somewhat iridescent, the marginal *ozema*, and basal areas only slightly darkened. Very common from Mexico to Colombia and Southern Brazil.

E. cajus Plötz (175 c) is somewhat larger, with a more bent costal margin of the forewing and *cajus*, a more pointed apex. The whitish wings are dusted more reddish-brown, the discal area of the forewing is not remarkably lighter, the dark antemarginal band is particularly on the forewing less dentate and more blurred. Beneath almost without markings except the antemarginal bands. Hitherto apparently only known from Peru and Bolivia.

24. Genus: **Xenophanes** G. & S.

Separated from the preceding genera by the shorter, more rounded wings without a costal fold; nor do the posterior tibiae exhibit a hair-pencil.

tryxus. **X. tryxus** Cr. (175 c). Above brownish-grey, dusted bluish with numerous hyaline spots arranged like a band; beneath at the proximal margin of the forewing and in the disc of the hindwing almost purely white. Everywhere very common from Mexico to Southern Brazil, generally not rising beyond altitudes of 3 to 4000 ft.

ruatanensis. **X. ruatanensis** G. & S. is probably of the same species. It is smaller and much darker, particularly on the under surface of the hindwing the white area is very narrowly confined, the hyaline spots smaller. Known only from the Island of Ruatan (Honduras).

25. Genus: **Carrhenes** G. & S.

Almost the same as the preceding, but the ♂♂ exhibit a costal fold and a brown hair-pencil on the posterior tibiae. On the forewing the upper median vein rises nearer at the lower cell-angle.

fuscescens. **C. fuscescens** Mab. (175 d) is above dark greyish-brown with a reddish shine, spotted darker in the shape of transverse bands, and with 7 minute hyaline spots, one of them in the cell, 3 subapical ones and 3 below them. Beneath somewhat lighter, of a reddish-yellow, marked as above with a black spot at the anal angle of the hindwing. Mexico to Honduras.

calidius. **C. calidius** G. & S. (175 d) is very similar, in the middle of the proximal margin of the forewing and in the disc of the hindwing brightened up by lilac whitish, whereby the macular band of the hindwing is more distinct. Beneath the hindwings are more whitish, the macular bands often almost extinct. Mexico to the Amazon.

chaeremon. **C. chaeremon** Mab. (175 d) is considerably larger, very similar, but with clearer and more distinct markings; wings in the basal and marginal areas more blackish-grey, in the disc lighter, particularly on the hindwing almost white. The ♀ is still larger, the bases of the wings darker, the rest whiter, the markings more feeble. Expanse of wings: 35 to 38 mm. Sao Paulo.

autander. **C. autander** Mab. resembles *Chiomara asychis* (178 a). Wings greyish-black with a marginal band of minute black spots being anteriorly pupilled whitish; at the apex there are 3 quadrangular hyaline spots, below them a blackish band; in the disc there are 2 black, interrupted dentate lines, between them whitish; in the submedian area a red-brown spot. The hindwing is brownish black, with an antemedian white band bordered with black, near the margin with a reddish-white macular band. Beneath the hindwing is white, at the proximal margin bluish with 3 blackish macular bands in the disc. Expanse of wings: 34 mm. Buenos Ayres.

besa. **C. besa** Mab. is dark greyish-yellow with 3 apical hyaline dots on the forewing, an oblong cell-spot with a small one at the costal margin above it and 4 behind it between the median and lower radial veins. Hindwing with a dark discal band, along the margin with small, indistinct, yellowish spots, also in the middle. The under surface is lighter, more yellow, the forewing with a bent row of 5 or 6 yellowish spots before the apex; on the hindwing beneath the light macular bands are more distinct, particularly the distal one; in the cell a round, yellowish-white spot. Expanse of wings: 28 mm. Patria unknown.

andraemon. **C. andraemon** Mab. has the size and shape of *chaeremon* (175 d). Wings dirty white, dusted light reddish-brown, the base of the forewing brown bordered by a darker colour, projecting below the cell, here with a quadrangular, light yellow spot; the discal area is almost white, at the costal margin with a brown triangle, the apex of which is situate at the cell-end; into the light brown marginal area the white discal area projects in 2 small spots between the radial veins. Hindwing brown, the costal margin as far as the middle white, behind it with 2 brown bands. Under surface white with a brown costal-marginal triangle. Colombia.

callipetes. **C. callipetes** G. & S. (175 d) resembles *fuscescens*, but it has more numerous hyaline spots; the spot at the cell-end is double, above them there is another spot at the costal margin; the discal spots are larger and extend almost to the proximal margin. The hindwing also shows 2 hyaline spots in the disc. Beneath the hindwing does not show a spot at the anal angle. From Southern Mexico to Colombia, everywhere rare.

meridensis. **C. meridensis** G. & S. (175 d) approaches *callipetes* and is easily discernible by the whitish-blue anal half of the hindwing beneath. Costa Rica, Venezuela.

canescens. **C. canescens** Fldr. (175 d, e) is another very similar species, smaller, of a paler colour, with smaller hyaline spots; on the forewing the dark spots are more distinct. Beneath the colour is still much paler, the spots very irregular. Widely distributed and common from Mexico to Colombia.

leada. **C. leada** Btlr. (175 c) is above in the disc still much paler, almost yellowish-white, so that a large, darker apical spot is very prominent, the basal area being darkened, too. Costa Rica to Paraguay.

dilucida. **C. dilucida** Mschlr. (175 c) is a species placed here as doubtful by MABILLE. Above greyish-brown, in the discal area strewn with red with 3 small apical hyaline spots and a broad discal hyaline band. The hind-

wing shows a very broad hyaline discal band and a narrow one behind it. Beneath white with greyish-black, spotted transverse bands. From Surinam.

26. Genus: **Potamanax** Wts.

This genus contains more than a dozen of rather small species with comparatively short and broad forewings, with a rather rounded apex, mostly dark-coloured, with a whitish or yellowish discal area. The antennal club is strong, bent. The 3rd palpal joint is rather long, straightly porrect. The cell of the forewing is short and narrow, the lower median vein rises almost just as distant from the base as from the upper median vein, the latter rising rather near the lower cell-angle. The posterior tibiae exhibit 2 pair of spurs, but no hair-pencil.

P. pammenes *G. & S.* (175 e) is a small species, above blackish-brown with a rather broad, white discal band which is rounded and narrowed on the forewing, not reaching the costal margin and with a faint yellow tint towards the proximal margin. The dark ground-colour is postdiscally somewhat lighter in the shape of a band. The under surface is much lighter, the hindwing as far as the base greyish-white. From Nicaragua. *pammenes*.

P. unifasciata *Fldr.* (175 e) approximates the preceding, but it is easily discernible by 5 minute, white, subapical dots and orange-yellow colouring at the proximal margin of the white discal band on the forewing. Colombia (Bogotá). *unifasciata*.

P. thoria *Hew.* differs from *pammenes* (175 e) by a considerably narrower white discal area, particularly on the forewing. Ecuador. *thoria*.

P. melicertes *G. & S.* (175 e) is likewise closely allied to the preceding and separable by the white discal area being slightly smoked in a brownish shade, reaching the costal margin on the forewing and being somewhat snapped off below the median veins, whilst on the hindwing it does not reach the proximal margin. From Panama (Chiriqui) and Costa Rica. *melicertes*.

P. flavofasciata *Hew.* (175 f) has only on the forewing a band of yellow colour shaped as in *pammenes*, the hindwing remaining quite black, except a lighter part at the costal margin at most. Ecuador, Bolivia. *flavofasciata*.

P. xantholeuce *Mab.* (175 f) has likewise a yellow discal band occurring, however, also on the hindwing. The wings are of a lighter brown, before the margin somewhat dark in the shape of a band, and also postdiscally at the costal margin and behind the cell clouded darker. Beneath the hindwing is bluish-grey in the anal half and at the base. Panama. *xantholeuce*.

P. fassli *sp. nov.* (175 f) is somewhat similar, but the yellow discal band on the forewing has the shape of an oval spot and reaches neither the costal margin nor the proximal margin. The light distal area is veined dark, while the band is not. The spot of the hindwing is of a purer white, at the costal margin very much expanded and scarcely extends beyond the median. Beneath the hindwing is almost entirely white, except a narrow brownish-grey marginal part with some small light spots in it, at the base it is somewhat bluish. Several specimens from Colombia (Rio Negro, Sosomoco) and Bolivia (Songo). *fassli*.

P. latrea *Hew.* (175 f) initiates another group of mostly somewhat larger species, in which the forewing shows behind the white, mostly darker veined discal area a second brownish, smoked band sharply intersected by the black veins, appearing in the present species between the median vein and lower radial vein and exhibiting above it towards the margin 2 smaller spots besides; the forewing exhibits an indistinct, antemarginal row of brownish dots. The white discal area is smoked brown towards the costal margin. From Nicaragua. *latrea*.

P. thestia *Hew.* (175 f) is in the ♂ similar, the band of the forewing broader, as far as the costal margin of a pure white, not reaching the proximal margin on the hindwing; on the forewing there is a yellow spot in the submedian area near the base. In the ♀ the band of the forewing is smoked grey. Ecuador. *thestia*.

P. paralus *G. & S.* (= *thestia* *Drc.* nec *Hew.*) (175 f, g) is almost the same, but it has a considerably narrower white band being still more shortened particularly on the hindwing. Peru. *paralus*.

P. effusa *sp. nov.* (175 g) is the most closely allied to *fassli* (175 f). The ground-colour is a much duller greyish-brown, the broad, whitish band extending from the costal margin to the proximal margin is distally not sharply defined; behind it there are yet some whitish diffuse spots, particularly distinct in the submedian area and between the radial veins. Hindwing as in *fassli*. Beneath almost entirely white. From East Colombia (Rio Negro). *effusa*.

P. confusa *sp. nov.* (175 g) is very similar, the band much narrower, quite faded and ochreous-yellow; also on the hindwing it is narrower and extends farther to the proximal margin, which is haired light greyish-blue. Beneath white, tinted ochreous, with a light blue base of the hindwing and a light brownish-grey apical part of the forewing and distal margin of the hindwing in which there are small light spots. From Panama. *confusa*.

- caliadne*. **P. caliadne** G. & S. (175 g) is likewise very closely allied to *thestia*, more variegated owing to the much broader, light brown postdiscal band and the light yellowish marginal dots; in the submedian area near the base of the forewing there is a large, white spot parted black by the fold; the broad, white discal area of the hindwing does not reach the proximal margin. Described from Costa Rica.
- violaceus*. **P. violaceus** Mab. (175 g) has an exterior somewhat similar to the preceding, but it probably scarcely belongs hereto owing to the shorter palpi and some other slight differences. Its size is very variable. The broad, white, black-veined discal band is at the proximal margin more or less yellow; at the cell-end small black discal spots may be present or absent; the marginal area on the forewing is extensively violettish-grey. From Peru and Bolivia. — As **fumida** form. nov. (175 h) I denominate specimens from the valley of the Rio Aguaca from the West Colombian Cordilleras, entirely dusted brownish-grey, except a conspicuous yellow spot on the proximal margin of the forewing and the light yellowish costal-marginal part of the hindwing. They look rather different, but are probably not a species of their own.

27. Genus: **Achlyodes** Hbn.

Distinguished from the preceding by the much shorter terminal joint of the palpi, and a less strong and less bent antennal club. On the forewing the lower median vein rises somewhat nearer at the base.

- fridericus*. **A. fridericus** Hbn. (175 h) is one of the smaller species; above black, on the forewing postdiscally irregularly blackish-brown band-shaped lighter, on the hindwing with a very indistinct lighter discal band. Beneath somewhat lighter with 2 scarcely lighter submarginal bands; on the hindwing the distal margin is greyish towards the anal angle, at the anal angle itself at least in more northern specimens distinctly spotted white; the light area crossed by a darker band. Panama to the Amazon and Brazil.
- calliginea*. **A. calliginea** Mab. (175 h) is very similar, on an average larger, and beneath always without whitish-grey on the hindwing. Mexico to Venezuela and Colombia.
- calavius*. **A. calavius** G. & S. (175 h) is an entirely monotonous blackish-brown species, beneath just a little lighter, at the proximal margin of the hindwing still lighter. Guatemala, Nicaragua, Panama.
- bubaris*. **A. bubaris** G. & S. (175 h) shows a small, apical hyaline dot and a light submarginal area on both wings. Described from Mexico.
- simplex*. **A. simplex** G. & S. (175 h, i) differs from *bubaris* by its larger size and 3 subapical dots. From Panama.
- cyrna*. **A. cyrna** Mab. (= *fasciata* G. & S.) (175 i) looks above exactly like *simplex*, but beneath the distal third of the forewing is orange or ochreous yellow in which there are 3 subapical dots. Panama.
- braco*. **A. braco** Plötz (175 i) is above deep blackish-brown with lighter antemedian, median and postmedian parts, more distinct in the ♀, in the shape of transverse bands. Beneath lighter, particularly towards the proximal margin more reddish-brown with darker macular bands in it. Panama to Brazil, Cuba.
- prudens*. **A. prudens** Plötz (175 i) is of a deep violettish-black, on the forewing postdiscally with a curved black macular band, behind it antemarginally lighter reddish-brown. Beneath lighter brownish, towards the proximal margin greyish with a darker, indistinct postdiscal band. Surinam, Cayenne.
- thiena*. **A. thiena** Plötz (175 i). Purple-brown, in the middle of the proximal margin of the forewing as far as the median black, above it with a cell-spot, and the beginnings of ante- and postmedian bands at the costal margin, before the darkened marginal part the band of the ground-colour is parted by a narrow, black, undulate line. Beneath somewhat lighter, more reddish brown, forewing indistinctly marked, hindwing with a cell-spot, a curved band behind it and a darkened margin. British Guiana; Pará.
- serapion*. **A. serapion** Plötz (175 i) is a very small species, doubtfully placed here. Above purple-brown with black transverse bands forming an angle on the median vein; on the hindwing they are somewhat finer and more indistinct. Beneath lighter, strewn darker, with indistinct markings. From Novo Friburgo.
- protius*. **A. protius** Plötz (= *pulverea* Mab.) (175 i). Above slate-coloured black with 2 curved black transverse bands and a similar antemarginal band interrupted in the middle on the forewing. Beneath lighter brownish, at the proximal angle of the forewing brightened up; here the proximal transverse band is absent. Brazil (Rio de Janeiro).
- violella*. **A. violella** Mab. is said to be a form of *fridericus*. Forewing without hyaline spots, black with deep violet macular bands, as if impressed, one at the base, one in the cell of 2 spots each, at the cell-end a broad band as far as the inner-marginal vein, behind it an undulate band of smaller spots, and before the black fringes a row of dots. Hindwing with 3 basal spots, 1 luna in the cell, behind it 3 separate macular bands. Beneath blackish, only at the base of the forewing light red-brown with the bands as above. Bolivia.

A. cyclops *Mab.* from Colombia and Guatemala has very broad forewings with a pointed apex, and *cyclops*. rounded hindwings protracted in the middle of the margin, with a slightly lobate anal part. All the wings are black, tinted reddish; at the apex lighter, traversed by dark bands. In the forewing before the apex a curved row of black dots from the costa to the middle of the wing, where it often disappears, at the costa centred white and behind exhibiting a whitish macula, and also above the dot very finely pupilled white.

A. colotes *G. & S.* (176 a). This species established according to but 2 ♀♀ entirely resembles *simplex colotes*. (175 h, i) above, but beneath it is very different: greyish-brown, on the hindwing and in the antemarginal area of the forewing lighter; the hindwing exhibits at the cell-end a band-shaped, dark spot and behind it a slightly bent, somewhat longer band, the base and margin being likewise darkened. Nicaragua and Panama.

A. oiclus *Mab.* is dark red-brown, the forewing with 2 broad, straight bands touching the proximal *oiclus*. margin in a right angle, and with 3 small subapical dots; hindwing with a rounded spot at the base, behind it a semicircular band. Beneath lighter brown, the hindwing in the anal half of the distal margin yellow into which colour a piece of the black postdiscal band extends. Panama (Chiriqui).

A. orsus *Mab.* This species is unknown to me and its appertaining to this genus is questionable. *orsus*. Above reddish-brown, with 3 small subapical dots and 2 broad, black, faded bands suffused with violet; the hindwing shows a similar cell-spot and a curved median band, the margin being darkened, too. Beneath lustrous lilac-grey, hindwing with 2 curved bands, one postdiscal and one antemarginal band, which terminate before the proximal margin. From Porto Cabello.

28. Genus: **Pachyneuria** *Mab.*

A very peculiar genus deviating by the doubly bent, very strong costal-marginal vein excelling the subcostal vein in thickness, and by the remarkably strong submedian fold. Distal margin nearly just as long as the proximal margin; on the forewing the middle radial vein is much nearer to the upper one than to the lower. Terminal joint of the palpi conical, rather long, set straight forward. Antennae with a long club and a fine, bent apex. Posterior tibiae fringed with 2 pair of spurs.

P. obscura *Mab.* (176 a) is lustrous olive-grey with thick, black veins and a dentate antemarginal *obscura*. line. Beneath dull black. Colombia, Peru, Bolivia.

29. Genus: **Praxis** *Mab.*

The only species known is a small insect with horizontally porrect palpi. Antennae with a fusiform club, bent round in the second third. Distal margin of forewing below the lower median vein with a concavity so that above it a small angle arises. Hindwing somewhat angled. Posterior tibiae with long, fluffy hair and 2 pair of short spurs.

P. quadrata *Mab.* is dark brown with a black basal stripe and a large, obliquely quadrangular spot *quadrata*. in the disc, one point of which touches the costal margin; apex likewise darkened. Hindwing with 2 shortened bands from the costal margin. Beneath reddish-brown, at the proximal margin of the forewing whitish. Described according to 1 ♂ from Massauary.

30. Genus: **Sostrata** *G. & S.*

The antennal club is longer than in the preceding genus, the 3rd palpal joint likewise longer. Forewing longer and narrower with a rounded distal margin and costal fold. Posterior tibiae with 2 pair of spurs. On the whole not dissimilar to the species of *Paches* and to some blue *Pythonides*.

S. scintillans *Mab.* (176 a) is blackish, towards the margin with a lilac reflection, strewn with numerous *scintillans*. silvery-blue, small scale-spots, and some narrow, black undulate bands, some postmedian, rather inconspicuous, small hyaline spots. Beneath lighter brown with darker, undulate transverse lines. Mexico to Brazil.

S. adamas *H.-Schäff.* (= *leucorrhoea* *G. & S.*) (176 a) is above the same, but beneath the anal part *adamas*. of the hindwing is bluish-white; also on the forewing the proximal margin is spotted white. From Panama to Colombia.

S. pusilla *G. & S.* (176 a) is considerably smaller, of a purer black and only towards the base *pusilla*. strewn with silvery blue; the subapical dots of the forewings are absent. Nicaragua; Panama; Amazon.

S. plumbago *Plötz* (= *chalybs* *Mab.*) (176 a) is brown with a broad, black transverse band strewn *plumbago*. with silvery blue. Beneath lighter brown with a yellowish base and proximal margin, the hindwing suffused with a lustrous grey, with a black macular band, in the middle double. From Peru (Chanchamayo).

31. Genus: **Milanion** Wkr.

Distinguished by the oblong shape of the wings with a comparatively short distal margin. The cell of the forewing is broad and short; costal fold absent. Antennal club long and sharp. Palpi thickly scaled with a long, black terminal joint. Posterior tibiae with a hair-tuft and 2 pair of spurs.

- hemes*. **M. hemes** Cr. (176 b) is black with small, white discal and cellular spots, and 5 white subapical dots in a curved row. The hindwing shows a very broad, white discal band extending from the costal margin to the proximal margin. In the ♀ the discal spots and the white area of the hindwing are enlarged. Guiana, Brazil.
- marciana*. **M. marciana** G. & S. (176 b) is very closely allied to *hemes*, but the white area of the hindwing is much broader and the forewing is without the white cell-spot. From Panama.
- marica*. **M. marica** G. & S. (176 b) almost looks like a *Potamanax*, the discal band of the forewing being much steeper and standing rectangularly on the proximal margin; the hindwings are longer, too, and thereby also the discal band ending towards the anal angle appears steeper. Nicaragua.
- leucaspsis*. **M. leucaspsis** Mab. is above blackish-brown with 5 subapical and 4 discal white spots. Of the latter that at the costal margin is small, in the cell there is a larger one. Hindwing with a broad, white transverse band. Beneath marked the same, but of a paler colour; on the hindwing the basal part is white, the white band broader. Abdomen above black, beneath white with a black anus whereby it differs from the closely allied, smaller *hemes* the abdomen of which is above belted white. From Cayenne and Brazil.
- clito*. **M. clito** F. (176 b) resembles *hemes*, but it has about the same shape of wings as *marica*, with a convex projection of the hindwing in the middle of the margin and a concavity below it so that a somewhat rounded anal lobe is created. The discal spots situate below the cell of the forewing are somewhat extended and the white spot of the hindwing has an oval shape and touches neither the costal nor proximal margins. Guiana, Brazil.

32. Genus: **Eantis** Bsd.

The genus contains some conspicuous representatives with a slender, bent antennal club, porrect palpi, with a broad second and rather short, conical terminal joint. The apex of the forewing is almost ensiformly pointed, the distal margin very convex, the hindwing very broad, rounded quadrangular. The posterior tibiae with a hair-pencil and 2 pair of spurs. Some species are very common; the black insects are fond of resting on umbels and other white blossoms, noticeable from afar, with their wings flatly spread, the apical part of the forewing being very much bent above the surface and hanging down.

- thraso*. **E. thraso** Hbn. (176 b) is a well-known, common species from Mexico through almost the whole of South America as far as Paraguay, also in the Antilles. Black, in the distal costal-marginal half of the forewing with an oblong-oval, brownish-grey, lighter part, in it at the costal margin itself a narrow dark spot; on both wings bluish-grey antemarginal spots, in the disc towards the proximal margin larger, brownish-grey, round spots which are more or less extinct in the darker ♀.
- ulpianus*. **E. ulpianus** Poey (= rossine Btlr.) (176 c) is somewhat similar, the bluish-grey marginal macular band appears as a straight, narrow band extending from the apex to the proximal angle and cutting off the strongly bulging distal margin. Instead of the light inner-marginal spots there is a broad, dark brown band projecting pointedly on the middle radial vein and being flawed towards the margin. Beneath very much dusted bluish-grey, particularly on the hindwing. From Brazil and Cuba.
- papinianus*. **E. papinianus** Poey (176 c) approximates *ulpianus*, the dark band of the forewing is here at the costal margin much broader, flown together with the cell-spot; the light marginal band is not prominent at all, instead of it a dark oblique line appears parting the apex and extending to the distal third of the proximal margin. Beneath only the anal half of the hindwing is dusted bluish-grey. Described from Cuba.
- pallida*. **E. pallida** Fldr. (? = mithridates F. ? = ozotes Btlr.) (176 d) is brownish-olive, with a lighter antemarginal oblique band and two indistinct, darker, undulate transverse bands and cell-spot. Beneath lighter brownish, the distal-marginal half almost whitish. Very common from Mexico to Colombia and Bolivia. Specimens flying at the latter locality seem to be constantly darker, but they are also found elsewhere.
- agylla*. **E. agylla** Mab. is somewhat larger and darker brownish-black than the preceding, in the basal third almost black, in the middle with an olive-green shine, before the apex are 3 white subapical dots, behind it a blackish-brown band expanded at the proximal margin; marginal area with a rather broad, black margin. The light area of the hindwing is reduced, with 3 dark brown bands. The under surface is light yellowish-brown, the hindwing blacker, the markings more distinct. The ♀ is larger, the apical dots more intense, behind them 2 more dots encircled by brown, in the cell a black spot. From Bolivia.

E. chlorocephala *sp. nov.* (176 d) is somewhat doubtful as to its position. Smaller than *pallida*, otherwise similar in the colour and marking, but the marginal area is not so broadly darkened, but only with a rather narrow, darker submarginal line. Three small, white subapical dots, the middle one being the smallest. Head and collar with a metallic green reflection. Under surface almost as above, but the hindwings are much darker brownish-black than the forewings. Bolivia (Rio Songo).

33. Genus: **Sebaldia** *Mab.*

Scarcely different from the preceding, but the ♂ exhibits a hair-tuft at the base of the costal margin of the hindwing above and a spot corresponding to it beneath. Only one well-known species:

S. busirus *Cr.* (= *sebaldus* *F.*) (176 e) is above deep dark brown with still darker macular markings, beneath the anal distal-marginal part of the hindwing is of a bright orange-yellow, in the ♂ with dark spots therein. From Mexico through Central America, Venezuela, Colombia, South East Brazil to Paraguay. In the Upper Amazon district the yellow of the hindwing beneath is reduced, in the Lower Amazon district and Guiana, also in Colombia, it disappears altogether: f. **obscura** *Mab.* — The larva is violettish-brown with alternately yellow and white belts, and lives on Citrus.

34. Genus: **Doberes** *G. & S.*

Separated from *Eantis* by the longer terminal joint of the palpi and much less ensiform apex of the forewing. The posterior tibiae exhibit only one pair of spurs and on the inside a hair-comb with short spiny bristles in it. Costal fold absent. Only 1 species.

D. hewitsonius *Reak.* (= *mexicanus* *Fldr.*, *ananius* *Plötz*) (176 d). Light brown with 2 chestnut-brown costal-marginal spots, the proximal one rectangular, the distal one before the apex triangular, two undulate darker bands particularly on the hindwing broadly surrounded with a lighter colour. Beneath especially the hindwings are strewn violet. Mexico.

35. Genus: **Masices** *G. & S.*

Distinguished from the preceding genus by the longer antennal club and shorter terminal joint of the palpi. The middle radial vein of the hindwing is almost absent.

M. anticus *Plötz* (176 d) is dark blackish-brown with a violet reflection, 2 black cell-spots and an oblique band of the forewing expanded towards the proximal margin, the margin darkened. Hindwing the same, but instead of the cell-spots there are 2 transverse bands. Beneath only little lighter, the cell-spots absent, and the apical half of the forewing somewhat lighter. From East Mexico. — In West Mexico, Costa Rica and Guatemala flies: f. **sobrinus** *G. & S.*, in which the apical half of the forewing beneath shows decidedly yellow colour. The ♀ is considerably larger.

36. Genus: **Antigonus** *Hbn.*

Well distinguished by the peculiar shape of the wings: the proximal margin of the forewing is very concave, the proximal angle extended to a lobe, the hindwing is extended like a tooth on the upper radial vein. The antennal club is semicircularly bent. Palpi as in *Eantis*. Posterior tibiae with hair-pencil and 2 pair of spurs. The ♂ exhibits a costal fold.

A. nearchus *Latr.* (= *ustus* *Hbn.*, *pausus* *Warr.*, *hippalus* *Fldr.*, *sataspes* *Fldr.*) (176 e) is above deep blackish-brown with darker macular bands, between them in some places with a violet reflection. The under surface is reddish-brown, in the ♀ more yellowish-brown, of the macular bands only the distal border-lines are dark, the bands themselves somewhat darker brown. Very common from Mexico to Southern Brazil.

37. Genus: **Systasea** *Edw.*

In its structure very near the preceding genus, but the tooth of the hindwing is shorter, mostly another small one below it, the distal margin below deeper concave, the apex of the forewing somewhat stunted. The slender antennal club is simply bent, the terminal joint of the palpi longer.

S. erosa *Hbn.* (= *westermanni* *Latr.*) (176 e). Dark brown, in the ♂ densely powdered with a bluish grey; the forewing exhibits 4 white subapical dots in a straight line, in the ♀ some more hyaline spots between the median and radial veins and 3 undulate, darker macular bands. Beneath marked the same, but the ground-colour in the ♂ is red, in the ♀ yellowish-brown. Mexico to Paraguay.

- funebria*. **S. funebris** *Fldr.* (176 c) is somewhat similar, more blackish-brown with 2 distinct, coherent transverse bands which are particularly on the hindwing acutely prominent; the distal one is here towards the margin bordered by a light grey stripe. Beneath lighter, red-brown, towards the margin on the forewing more yellowish-brown; in the distal transverse stripe of the forewing there are here, more distinct than above, some small hyaline spots proximally sharply bordered by dark. Mexico.
- corrosa*. **S. corrosa** *Mab.* (= *sericus* *Plötz*) (176 c) is above blackish-brown with a violet reflection; one antemedian and one postmedian jet-black transverse line; in the distal one being very much curved there are 3 white subapical hyaline spots and farther below two more; it is thickened into spots on the hindwing at the costal margin, the proximal one on the forewing projects in the middle angularly towards the base, in the cell of the hindwing angularly towards the margin. Beneath red-brown, marked as above. Mexico to Guiana.
- liborius*. **S. liborius** *Plötz* (176 c) is above not dissimilar; between the two transverse lines a third is inserted on the forewing. The small median hyaline spots are absent in the ♂, whilst in the more greyish-brown ♀ they are present. At the costa of the forewing there is another small hyaline spot at the proximal band; body and base of wing show a greenish reflection. The under surface is more blackish-brown, in the anal half of the hindwing whitish. Bahia, Chapada.
- incisa*. **S. incisa** *Mab.* (= *aserea* *Plötz*) (176 c) is likewise similar, much smaller, darker, the 2 transverse bands broader, more faded, the proximal one on the hindwing reduced to a cell-spot. The forewing shows 2 white, subapical hyaline spots. Brazil.
- pulverulenta*. **S. pulverulenta** *Fldr.* (= *taeniatu*s *Plötz*, *zampa* *Edw.*) (176 e) is brownish-grey with a white-hyaline, narrow median band distally projecting pointedly with 2 teeth on the median veins, whilst towards the costal margin it is distally, towards the proximal margin proximally bordered with a ferruginous yellow; marginal area especially towards the apex darkened. Hindwing in the disc and marginal area more extensively mixed with a ferruginous yellow, with a lighter bluish-grey transverse line in the distal area. Beneath the hindwing is almost white. From Arizona to Guatemala.
- emorsa*. **S. emorsa** *Fldr.* (176 e) is a very variable species from Mexico, light greyish-brown, on both wings towards the proximal margin dusted bluish-white, with two whitish, partly hyaline macular bands and a very large, roundish spot behind the cell. Beneath almost white, only towards the margin light yellowish-brown, at the anal angle with a black spot. — At the same place and time there fly specimens with a very broad, purely white discal area on both wings and a more darkened base and marginal area: **albimedia** *form. nov.* (176 f), without showing any real transitions, for which reason it may be a species of its own.

38. Genus: **Staphylus** *G. & S.*

It forms together with *Bolla* *Mab.* one of the most difficult Hesperid genera. Many species are externally scarcely separable, at most by slight differences in the length of the last palpal joint, the palpal covering or other minute details, above all by the shape of the male genitals. The antennal club is somewhat obtusely pointed, the thickening unilateral, so that the other side is concave. Costal fold present. The upper median vein rises a little before the cell-angle. The distal margin of the hindwing is somewhat indented below the subcostal vein. The 3rd palpal joint is rather long, straightly porrect, the two first joints long-haired. The posterior tibiae show 2 pair of spurs, no hair-pencil, but they are long-haired. We combine *Bolla* *Mab.* with it, the palpi are here somewhat shorter, the hindwings more rounded.

- mazans*. **St. mazans** *Reak.* (= *ascalaphus* *Stgr.*, *oeta* *Plötz*, *vincula* *Plötz*) (176 f) is blackish-brown as all the following are, in some places particularly the ♀ scantily strewn with somewhat lighter, yellowish scales, with 2 very indistinct, broad, faded, darker transverse bands and 2 small white subapical dots on the forewing, which may also disappear. The hindwing is in the cell and band-shaped behind it somewhat lighter spotted. Mexico to Colombia and Venezuela, also in Trinidad, everywhere very common.
- hayhursti*. **St. hayhursti** *Edw.* is very closely allied to *mazans*; the colour of the wings is decidedly lighter with a prominent dark marking, and below purely white palpi which in *mazans* are intermixed with grey hair. It may be the northern representative of *mazans* from the southern United States, occurring, however, also in Mexico.
- scoramus*. **St. scoramus** *Schs.* has the same shape of wings. Yellowish scales are interspersed into the ground-colour, the dark markings are almost entirely extinct; the scales form an antemarginal row of small, indistinct, greenish yellow spots, the same in the disc and near the base; 2 small subapical dots are present. Beneath of a duller colouring, the small subterminal spots a little more distinct, particularly on the hindwings. Palpi dark grey. Expanse of wings: 26 mm. Peru.
- anginus*. **St. anginus** *Schs.* (176 f) does not differ above from *mazans*. Beneath dark brown, the hindwing in the anal half thickly strewn with grey and with a white strigiform spot at the cell-end. Expanse of wings: 21 mm. Novo Friburgo (Southern Brazil).

St. minor Schs. has likewise the same shape as *mazans*. The colour is a duller brown, scantily strewn *minor*. with 3 indistinct darker grey transverse lines near the base, in the disc and before the margin, which are parted into spots by the veins; the small subapical dots are absent. Beneath lighter brown, especially at the costal margin and apex of the forewing, at the base, proximal margin and anal angle of the hindwing strewn yellowish. Expanse of wings: 19 mm. Peru.

St. tadus Schs. has a more uniformly undulated distal margin of the hindwing than *mazans*; the *tadus*. subapical hyaline dots are absent. Wings dark brown, scantily strewn light yellow; in the middle and before the margin minute, very indistinct, grey spots. Beneath of a duller brown with a grey cell-end streak of the hindwing, the small grey spots more distinct than above. Expanse of wings: 26 mm. Novo Friburgo.

St. aztecus Scdd. (176 f) is also like *mazans*, but the hindwings entirely margined, rounded, not *aztecus*. undulate, and below the apex not excised. The colour is lighter than in *hayhursti*; the forewing exhibits 3 subapical dots. Mexico.

St. brennus G. & S. (176 f) is above almost uni-coloured blackish-brown, scantily strewn with *brennus*. ochreous, with a but little lighter submarginal band; subapical dots absent. Palpi below clad with long, black and yellow scales. Panama.

St. giselus Mab. (= eusebius Plötz) (176 f) entirely resembles *brennus*, but it has 3 subapical dots. *giselus*. Colombia (Bogotá). — f. *subgisela* Strd. has besides 1 or 2 small discal dots. *subgisela*.

St. evippe G. & S. (176 f) approximates *giselus*, but the palpi are beneath of a purer white; the *evippe*. 2 subapical dots are more or less extinct, the first being often entirely absent, whilst in the ♀ they are better visible. Mexico to Guatemala.

St. orsines G. & S. (176 g) is similar, much larger, more monotonously black without subapical *orsines*. dots; palpi longer porrect, below whitish, the apex of the forewing is sharper, the distal margin straighter, the genitals are very different. Mexico.

St. terreus Schs. is above dark greyish-brown with darker brown bands at the base, in the middle *terreus*. between the median and the proximal margin with a cell-spot above it, and in the distal area with a fine ante-marginal line and at the distal margin large spots flown together towards the apex. Beneath dark brown with a light grey antemarginal band; anal half of hindwing grey, traversed by a brown band, at the cell-end with a grey streak. Expanse of wings: 29 mm. Venezuela.

St. holophegges Dyar (176 g) is above black with a slight bronze reflection, without any markings *holophegges*. at all; beneath brownish-black. Palpi beneath grey intermixed with white scales; ventrum whitish-grey with a black discal line. Expanse of wings: 22 mm. Mexico (Misantla), taken in July.

St. litus (176 g) is likewise black with a slight bronze tint, unmarked; head and collar scantily inter- *litus*. mixed with coppery scales. Beneath black with a greenish shine; palpi below, chest and a double line on the ventrum white; in the fringes of the apex of the forewing some white scales. Costal fold yellow. Expanse of wings: 25 mm. West Mexico (Sierra de Guerrero), taken in June.

St. alicus Schs. Dark brownish-grey with black transverse bands in the middle and behind it, similar *alicus*. basal area and marginal spots; on the hindwing the dark basal area is flown together with the discal band. Forewing beneath dark brown, at the proximal margin lighter, the distal margin tinted violet; hindwing violettish-brown with the darker brown markings of the upper surface. Expanse of wings: 24 mm. South East Brazil.

St. subapicatus Schs. Head and palpi brown intermixed with yellow hairs. Forewing dark brown *subapicatus*. with a darker, oblique discal shade and a distal one being slightly bent towards the costal margin and composed of oblong spots; similar antemarginal spots; hindwing with a cell-spot and narrower discal and distal bands flown together at the costal margin; marginal spots irregular. Beneath the forewing is dark brown, at the costal margin, distal margin in the lower half and before the apex grey, the apex itself dark brown, hindwing somewhat lighter than above. Expanse of wings: 36 mm. Songolica (Mexico).

St. cylindus G. & S. (176 g) is likewise a larger species resembling somewhat *Achlyodes simplex cylindus*. (175 h, i) and *cyclops*, distinguished by the darker distal margin of the forewing beneath, which is ochreous-yellow in *cyclops*. Mexico to Costa Rica and Colombia.

St. imbras G. & S. (176 h). The ♂ is without the subapical dots, whilst the ♀ has 3 of them. Palpi *imbras*. longer than in *brennus* (176 f) which the species resembles very much. Mexico.

St. melangon Mab. is allied to *imbras*, but it has a grey base of the wings, and in the disc of *melangon*. the hindwing 2 grey transverse bands. Patria unknown.

St. saletas G. & S. differs by the wings being decidedly tinted ferruginous-brown, the dark transverse *saletas*. bands being more distinctly pronounced. Palpi below white, not yellow. The forewing shows 2 subapical dots, the ♀ besides 3 hyaline dots in the disc. Guatemala.

- cremerus*. **St. evemerus** *G. & S.* (176 g) is blackish-brown with 3 indistinct, darker transverse bands than the other species, the ♂ without, the ♀ with 3 subapical dots. Palpi below ochreous-yellow intermixed with black hairs. Genital organs very different. Costa Rica.
- unifascia*. **St. unifascia** *Mab.* (176 g) has more blackish-grey wings, the ♂ with one, the ♀ with 2 subapical dots, with a darkened basal area. Palpi below whitish. Mexico, Honduras, Panama.
- cupreiceps*. **St. cupreiceps** *Mab.* (176 g). Blackish-brown with a bronze tint, at the base darker; forewing with a faded, reddish postdiscal band; hindwing with a black postmedian macular band, the margin darkened more in the shape of a band. Beneath with a more yellowish tone and more distinct bands. Palpi, head and collar orange-coppery. Mexico to Bolivia and East Brazil.
- aurocapilla*. **St. aurocapilla** *Stgr.* (= *vulgata* *Mschlr.*) (176 h) is most similar, smaller, palpi below dull yellowish-white, the genital apparatus quite different. The ♂ without, the ♀ with 3 subapical dots. From Mexico to Argentina.
- flavipalpis*. **St. flavipalpis** *Plötz* (176 h) has somewhat longer extended forewings of a dark blackish-brown colour with the usual, faded, broad, dark transverse bands and 3 subapical dots, the middle dot being removed somewhat proximally. Beneath somewhat lighter brown. Face and palpi below ochreous-yellow. Copiapo (Chile).
- ceos*. **St. ceos** *Edw.* differs from *aurocapilla* by the longer palpi being below purely white. Forewing of the ♂ with 2, of the ♀ with 3 subapical hyaline dots. Arizona, Mexico.
- ascalon*. **St. ascalon** *Stgr.* is closely allied to *mazans* (176 f), but larger. Particularly different by the hindwing beneath being dark only in the costal-marginal part, but in the proximal area light whitish-grey, especially at the anal angle. At the costa of the forewing 3 very minute dots below each other, a larger hyaline spot at the cell-end and behind it another fine one recognizable with the lens. Described according to 1 ♂ from Novo Friburgo in South Brazil.
- epicaste*. **St. epicaste** *Mab.* is above blackish-brown; on the forewing extend 2 almost straight transverse bands, one in the disc, the second postdiscally, touching neither the costal margin nor proximal margin; in the median band there are 2 hyaline dots at the costal margin; margin narrowly darkened; on the hindwing both bands are angled. Beneath more reddish-brown with extinct bands. Palpi below white. Expanse of wings: 22 mm. Brazil.
- cupreus*. **St. cupreus** *Mab.* Wings black, above indistinctly undulate, with 3 very small white apical dots, thorax and vertex with a coppery lustre. Beneath the wings are black, at the costal margin paler, hindwings blacker. Brazil.
- phylo*. **St. phylo** *Mab.* Blackish-brown; forewing with a light, ochreous antemarginal band and a quadrangular cell-spot; 3 minute subapical hyaline dots. The hindwing exhibits a similar, undulate band parallel to the distal margin and 2 in the disc. Beneath the distal margin is broadly lighter. Palpi below white, apex blackish-brown. Expanse of wings: 27 mm. Brazil.
- hilarina*. **St. hilarina** *Mab.* is the size of *Zopyrion satyrina* *Fldr.* (177 h). Reddish blackish-brown, margin somewhat convex. On the forewing before the distal margin a narrow, spotted, lighter, reddish band, on the hindwing it is broader though more extinct. Beneath the same, at the distal margin lighter; hindwing in the anal half whitish. Described from Pará.
- tyro*. **St. tyro** *Mab.* is as large as *mazans* (176 f); above black with traces of a reddish antemarginal line, in the disc of the hindwing strewn reddish. The under surface is lighter, at the distal margin of the forewing somewhat lighter; the hindwing shows a reddish-grey antemarginal line and two similar cell-dots. Palpi yellowish, at the apex black. Brazil, Venezuela.
- tetra*. **St. tetra** *Mab.* entirely resembles the following *pullata*, but it is more of a slate-colour, with 3 subapical dots and a narrower marginal band. Fringes broader black. Forewing at the apex more pointed. From Cayenne.
- pullata*. **St. pullata** *Mab.* The broad wings are brownish-black, hindwing quadrilaterally rounded. On all the wings there is an indistinct marginal band tinted ochreous, parallel to the distal margin, the hindwing with a similar cell-dot; on the forewing 2 quite minute subapical hyaline dots. Beneath coloured the same, the marginal band fused with the lighter distal margin, the light cell-dot of the hindwing more distinct. Brazil.
- zorilla*. **St. zorilla** *Plötz* (176 h) is unknown to me in nature; it is said to be very closely allied to *giselus* (176 f), but it has 2 distinctly separated subapical hyaline dots; it is much smaller with a whitish costal fold of the ♂. Panama.
- cordovanus*. **St. cordovanus** *Plötz* (= *tucumanus* *Plötz* ex errore) (176 h) is a very small species with a very minute hyaline dot far away from the apex. Hindwing towards the proximal margin somewhat lighter brown. From Cordova (Argentina).
- chlorocephala*. **St. chlorocephala** *Plötz* (176 h) is a small species: blackish-brown with 2 black macular bands, a golden green head and collar, and easily recognizable by the hindwing being beneath in the anal half of a bluish whitish-grey colour, traversed by 2 undulate brown transverse lines. Brazil.

39. Genus: **Diaeus** *G. n. S.*

Very closely allied to *Systasea* (p. 903) and distinguished by the longer and more porrect 3rd palpal joint. Costal fold absent. Posterior tibiae with 2 pair of spurs and a hair-pencil. On the hindwing the upper median vein rises much nearer at the cell-end.

D. lacaena *Hew.* (176 i) is a small, pretty species easily recognizable and in no way mistakable *lacaena*, by the white discal area, the red-brown basal area and the blackish-brown apical area with black dentate lines. Mexico to Costa Rica and Panama, and reported as doubtful from Brazil. — f. **lacaenina** *Mab.* (*Stgr.* i. l.) (176 h) *lacaenina*, from Colombia (Rio Negro) is somewhat larger and darker.

D. variegata *Plötz* (176 i) is similarly marked, but much darker, monotonously greyish-brown with *variegata*, an olive tint in the ground-colour, without the red-brown apical spot. Beneath the colour is more whitish. From Brazil (Rio de Janeiro).

40. Genus: **Onenses** *G. n. S.*

Well distinguished by the forewing being long-dentate on the median veins; the anal angle extended like a lobe. Cell of forewing long and broad, costal fold absent. Hindwing likewise with 2 teeth on the upper median and upper radial. Antennal club long turned round. Palpi long porrect, the horizontal terminal joint hidden. Posterior tibiae with 2 pair of spurs and a hair-pencil. Only one species:

O. hyalophora *Fldr.* (176 i) is unmistakable for its large vitreous areas. From Mexico to Panama, *hyalophora*, reported also from Texas.

41. Genus: **Timochares** *G. n. S.*

Separated from the preceding genus by the entirely margined wings with a somewhat stunted apex of the forewing, with a very long costal fold. The horizontal palpal terminal joint is longer porrect.

T. trifasciatus *Hew.* (= hemula *H.-Schöff.*) (177 a) is pale brownish, the hindwing lighter yellowish *trifasciatus*, with 3 oblique, undulately dentate transverse lines. The ground-colour is variable, and dark (= **obscurior** *obscurior*, *form. nov.*) (176 i) and light forms fly together at the same places. From Mexico through the whole of South America to Argentina.

T. ruptifasciatus *Plötz* (177 a) is similar, but the transverse lines are broken up into macular bands. *ruptifasciatus*, Mexico.

42. Genus: **Ebrietas** *G. n. S.*

In the veins corresponding with the preceding genus, but the shape of the wings is much broader, the proximal margin is somewhat concave; the costal-marginal vein terminates before the cell-end, in *Timochares* a little behind it. The 3rd palpal joint is somewhat longer.

E. osyris *Stgr.* (177 a) is a well-known species, easily recognizable by the orange-yellow anal part of *osyris*, the hindwing beneath which is traversed by brown undulate lines; the apex of the forewing is likewise somewhat orange beneath. Above deep blackish-brown with black macular bands and cell-spots. Mexico to the Amazon.

E. infanda *Btlr.* (= perfidus *Mschlr.*, patens *Prittw.*, bodia *Plötz*) (177 a) is above very similar, *infanda*, but the hindwing beneath is quite brown, only somewhat lighter than above. The forewing is below the apex somewhat more deeply excised. Colombia, Peru.

E. undulatus *H.-Schöff.* (= anacreon *Stgr.*, tortricinus *Plötz*) (177 b) is smaller than the preceding, with *undulatus*, an intense violet tint, the macular bands deep velvety black, also beneath much darker, more blackish violettish-brown. Mexico to South Brazil. — In Guiana and Bolivia flies a very characteristic form: **evanidus** *Mab.* (177 b). *evanidus*. The blackish base is distally bordered by a straight ashy-grey band; the black median band is complete and forms in its centre a more or less angular spot, whereas the two distal bands are almost or entirely absent, the distal one being mostly indicated only by spots at the proximal margin, the proximal one at the costal margin.

E. livius *Mab.* (*Stgr.* i. l.) agrees with *undulatus* (177 b) in the size and colour; the marginal band *livius*, is narrow, spotted, the inner-marginal spot small; the postmedian band is double at the apex, thin, united with the 3rd in the cell. In the submedian area there is a straight band near the base, separated from the black base only by a scarcely lighter band. Hindwing with 3 rather broad black bands, the marginal one more spotted

than the others. Forewing beneath blackish, marginal area lighter, ferruginous-reddish, especially at the proximal margin. Hindwing in the posterior half light ferruginous-brown, the black bands hardly visible. Bolivia.

- lachesis.* **E. lachesis** Schs. looks like *osgris* (177 a) and is above separated by a small hyaline spot in the upper angle of the black cell-spot and a subapical hyaline spot. Beneath the yellow of the hindwing extends in 2 antemarginal rows of spots to the costal margin, and the proximal angle of the forewing also shows 2 yellow spots. Mexico (Tabasco).
- eclyptica.* **E. eclyptica** Btlr. (177 b) is extremely similar to the preceding, the proximal half of the forewing is much more monotonous in the colouring, darker, without the violettish-grey dusting. The posterior tibiae are without the hair-pencil which is present in the two preceding. Mexico to the Amazon.
- claudia.* **E. claudia** Plötz (176 i) is above very similar to *undulatus*, easily discernible by the hindwing beneath being coloured bluish-grey in the larger anal half. Venezuela. — **E. triseriata** Plötz (176 i) is presumably only a form of it with a still more extensive and more violettish whitish anal part of the hindwing beneath, so that there are 3 transverse bands in it; the forewing is also somewhat whitish at the apex and proximal angle. Venezuela.
- chacana.* **E. chacana** Plötz (177 b) from Panama is very closely allied to *claudia*, but much smaller. The upper surface shows much more faded band-marking, the hindwing beneath is in the anal half of the distal margin only narrowly bluish-grey, so that only one transverse band is in it.
- eremita.* **E. eremita** Plötz (177 b) is larger, above dusted lavender-grey, with distinct, coherent macular bands, in the cell there is only one shortened spot. The hindwing beneath is almost quite whitish bluish-grey, only the costal-marginal part is narrowly greyish-brown. South America.
- impressa.* **E. impressa** Mab. (177 c) is blackish, without any violet tints. Forewing at the base and apex lighter, in the discal area darker. Hindwing almost uni-coloured with 2 indistinct darker transverse bands. Beneath lighter brown. Palpi below grey. From Panama to Bolivia.

43. Genus: **Camptopleura** Mab.

The palpal apex is obtuser than in the preceding genus. The forewing shows a costal fold in the end of which the costal margin forms an obtuse angle; the broad hindwing is regularly rounded, otherwise all agrees with *Ebrietas*.

- theramenes.* **C. theramenes** Mab. (= *auxo* Mschlr.) (177 c) is dark brown, with deep violettish-black bands and watered in the same colour. The under surface is lighter with 2 dentate darker bands near the distal margin. The proximal margin is somewhat lighter. Mexico to South Brazil.
- ebenus.* **C. ebenus** Mab. in its size and colouring resembles *Brachycorine arcas* (Drury), but it is still blacker, forewing scantily strewn with small grey scales behind and below the cell. Beneath unmarked, only at the margin somewhat lighter. By the angled costal margin it belongs here. From Bolivia.
- iphicrates.* **C. iphicrates** Mab. has very broad wings; blackish-brown, strewn with a greyish blue, the undulate lines reddish black. Hindwing more reddish ochreous-brown, broadly margined dark, with 2 blackish-brown marginal bands. On the under surface all the lines are light reddish-brown, in the disc almost whitish, unmarked, with a darkened apex of the forewing; hindwing reddish-brown with a narrowly darkened distal margin. Very closely allied to *thrasybulus*, but constantly differing. From Cayenne and Brazil.
- termon.* **C. termon** Hpffr. (= *strigulosa* Stgr. i. l.) is likewise very closely allied to *thrasybutus* (177 c), but differing by the marking and colouring. Above more ochreous-grey, the costal and distal margins red-brown with 3 red-brown, spotted undulate lines, at the border greyish-blue with a sagittally spotted marginal band strewn with blue. Hindwing still lighter greyish-ochreous, distal margin and 2 undulate bands dark brown. Beneath the forewing is whitish-ochreous, the costal margin of the forewing, 2 confluent marginal bands, hindwing with 2 costal-marginal spots and apex darker. Length of forewings: 19 mm. Peru (Chanchamayo).
- tisias.* **C. tisias** G. & S. (177 c) looks very much like *C. thrasybulus*; the markings are more regularly linear, not so faded, the ground-colour is of a more uniform tint. Costa Rica; Panama to the Amazon.
- cataphanes.* **C. cataphanes** Mab. is smaller than *theramenes* (177 c) and most closely allied to *termon*; the violettish bluish-black markings are finer, more distinct, towards the base they disappear more under the lavender-grey dusting which covers the costal-marginal part and basal part as well as the body. Beneath blackish, the proximal angle of the forewing whitish in the ♀, at the costal margin there is a very distinct, black macular band; hindwing in the ♂ in the anal half light red-brown, in the ♀ as far as the middle of the cell whitish with 2 black bands and 2 cell-spots. Fringes black. Sa. Catharina.

44. Genus: **Cyclogypha** Hbn.

Very closely allied to the preceding genus and distinguished by a stronger antennal club, longer terminal joint of the palpus, and a more pointed apex of the forewing. The costal margin of the hindwing is strongly angled behind the proximal third, and shows a long hair-pencil at the rise of the costal.

C. thrasybulus *F.* (177 c) is above violettish-black with velvety-black dentate lines, beneath more *thrasybulus*, reddish-brown with duller markings, and in the ♂ with a lighter, lilac-grey apex and a lighter proximal margin of the forewing. Very common from Mexico to Southern Brazil.

C. caeruleonigra *Mab.* is very similar, somewhat smaller, the dentate lines more coherent. Beneath *caeruleo-nigra*, black, at the costal margin and apex reddish-brown, the base of the costal margin and the proximal half of the cell as far as the proximal margin of a pure bluish-white; distal margin of hindwing reddish-brown, more or less dusted light blue. Guiana.

45. Genus: **Haemactis** *Mab.*

Antennae short, slender with a small, bent club; terminal joint of palpus almost as long as the second, bent forward. Forewing elongate, produced on the lower radial vein, below the apex concave, like the hindwing. The bare posterior tibiae exhibit only one pair of spurs. Only one species:

H. sanguinalis *Dbl. & Hew.* (177 d) is a small, black and red species resembling certain *Erycinidae sanguinalis*, and not to be mistaken for any other species. Ecuador and Bolivia.

46. Genus: **Diphoridas** *G. u. S.*

Allied to the preceding genera. Terminal joint of palpus still longer, the margin of the forewing more convex, below the apex and above the proximal margin somewhat concave, costal margin before the apex likewise slightly concave. Costal fold absent. Posterior tibiae with 2 pair of spurs and a hair-pencil.

D. phalaenoides *Hbn.* (177 c) is a common, small species with similar characters of the marking as *phalaenoides*, in *Cycloggypha*, but the transverse lines are finer, more numerous and particularly prominent as a bent ante-median transverse line and towards the distal margin near the proximal angle; apical half of the costal margin on the hindwing much darker. Beneath of a duller brown, more monotonous, in the anal half of the hindwing occasionally somewhat lighter lilac-grey. Mexico to Paraguay.

D. palpalis *Latr.* (= *aura* *Plötz*, dichrous *Mab.*) (177 d) is very similar, somewhat larger, hindwing *palpalis*, more brownish, beneath in the anal half whitish. Panama to Brazil.

47. Genus: **Gorgythion** *G. u. S.*

Very similar to the preceding genera, the palpi not quite so long, the shape of the wings broader, at the distal margin less concave, the apex somewhat stunted. Otherwise the same as in *Diphoridas*.

G. pyralina *Mschlr.* (177 d) is light violettish-brown with black macular bands particularly prominent *pyralina*, in the anal half of the forewing in the shape of spots, above them in a row of spots 3 or 4 spots are strewn with bluish-white; 2 minute subapical hyaline dots. Beneath duller greyish-brown. Common from Mexico to Southern Brazil. — f. **marginata** *Schs.* (177 d) presumably belongs hereto; it differs by the broad blackish-brown margin of the hindwing. Described according to 2 Peruvian specimens.

G. begga *Prittw.* (= *alcandra* *Mab.*) (177 d) is above scarcely separable from the preceding, but *begga*, the hindwing above is blacker towards the apex; the chief mark, however, is the hindwing beneath being whitish in the anal half. Mostly common from Panama to Paraguay.

G. beggina *Mab.* (177 d) is above much lighter, light yellowish-violet, whereby the macular bands *beggina*, are much more conspicuous than in the other species; the markings are otherwise almost the same. The hindwing is beneath in the anal half still purer and more extensively white with more feebly prominent markings. Bolivia.

G. beggoides *Schs.* is another very closely allied species. Above greyish-brown, with similar macular *beggoides*, markings as the others, but more confluent; the postcellular row of spots consists of large, elongate spots between the veins; the marginal spots are confluent towards the apex; subapical spots entirely absent; on the light brown hindwing the dark markings are nearly all broadly flown together. Beneath also the forewing shows whitish at the apex and proximal angle, the hindwing a broad white proximal margin and anal angle, white spots in the cell and at the cell-end, and whitish diffuse patches before and on the margin. Expanse of wings: 15 mm. An insular form from Trinidad.

48. Genus: **Anisochoria** *Mab.*

Distinguished by very long, beak-shaped palpi; antennal club strong, curved bow-like and finely pointed. Costal margin of forewing strongly convex, the apex appearing somewhat stunted. Costal fold absent. Border of hindwing regularly rounded. Posterior tibiae with 2 pair of spurs.

A. polysticta *Mab.* (= *lemur* *Mschlr.*) (177 d, e). Above brownish-black, with an oblique row of *polysticta*, 6 very small white hyaline spots from the middle of the costal margin to the proximal angle, 3 small apical spots and 2 or 3 below them. Beneath somewhat lighter brown, in the distal part of the forewing still lighter, in the apex somewhat reddish. Hindwing lilac-grey, watered blackish; with 3 faded brownish transverse bands and ferruginous spots below the costal margin. Common from Mexico to Guiana and Peru. Southern specimens are mostly much darker, the small discal hyaline spots almost disappearing, beneath on the hindwing appear larger chestnut spots.

- pedalioidina*. **A. pedalioidina** *Btl.* Upper surface jet-black, the forewing towards the apex and margin lighter with an irregular antemarginal stripe; near the apex 5 hyaline spots, in the disc 2. The body is also jet-black. Beneath the wings are lighter, with irregular grey bands and dark brown shades. Forewing with an auburn apical spot. Hindwing with 2 large auburn costal spots and an auburn central dot. Length of wings: 1.9 inch; in the colouring it resembles a *Pedaliodes* (t. 35). The exact patria is not known.
- sublimbata*. **A. sublimbata** *Mab.* has only 3 subapical hyaline dots and a light antemarginal band of both wings, which may be divided into spots. Beneath the hindwing is olive at the base and margin. Colombia.
- minorella*. **A. minorella** *Mab.* resembles the preceding and varies in the size. Above blackish or greyish-brown with 3 subapical dots from which a darker stripe runs down, marked by lighter dots, which are occasionally transparent; at the cell-end 3 small hyaline spots. On the hindwing a dark brown postmedian transverse band on both sides bordered with a somewhat lighter yellowish. The dirty grey fringes are speckled black. Forewing beneath greyish-black, in the marginal area lighter yellowish, at the cell-end a black streak, the apical dots pronounced by black angular streaks. The hindwing shows in the disc a large blackish spot appearing to be strangulated in the middle; its anterior half is square with a black appendage towards the proximal margin, which is bordered with white. Marginal area light grey, towards the costal margin light ochreous. Bolivia.
- bibiana*. **A. bibiana** *Plötz* (177 e) is above light greyish-brown with 3 small subapical spots and a fourth above the upper median vein; at the cell-end 2 small light spots; disc of hindwing traversed by a darker arcuate stripe. Beneath lighter yellowish-brown, watered somewhat darker, marked as above. Hindwing still lighter and more yellowish, at the base a darker spot; from the costal margin as far as into the cell a large, brown, triangular spot, on the apex of which there are 2 black dots below the cell. In the marginal area 2 darker brown stripes. Fringes speckled black. This species described from Colombia is probably identical with one of the allied species.
- superior*. **A. superior** *Mab.* is a larger species, above black with lighter margins, 3 apical dots and a lighter grey marginal stripe, towards the proximal angle on both sides bordered by triangular black dots. Beneath a two-pointed white spot is distally attached to the middle subapical dot; in the middle of the marginal area there is a lighter moon-spot. Hindwing ashy-grey, watered black, at the costal angle with a triangular brown spot which may also be bipartite; it occupies the whole cell and is situate with the apex towards the base; at the lower radial vein and towards the proximal margin it is bordered with white. Bolivia.
- subpicta*. **A. subpicta** *Schs.* is described as dark brown with a darker distal margin and lighter subterminal spots towards the apex; 3 hyaline subapical dots. Beneath the forewing is dark brown with a light brownish area at the apex and proximal angle, in the former dark grey spots; the middle of the distal margin is tinted olive. Hindwing isabel-coloured mixed with olive and watered dark; a light discal line terminates in the cell with a silvery spot, below it a black spot. Expanse of wings. 33 mm. Castro, Paraná.
- oligosticta*. **A. oligosticta** *Mab.* is larger than *polysticta* and of a deeper black, the forewing towards the margin more auburn with 3 white subapical dots; postdiscally only 3 small punctiform spots, the two upper ones double. Hindwing unmarked with reddish fringes. Beneath at the proximal angle more auburn, the hindwing with a large, purple costal-marginal spot, at the distal margin and proximal margin grey, darker reticulate in the shape of bands. Expanse of wings: 41 mm. Colombia.
- albida*. **A. albida** *Mab.* (177 e) above almost resembles a *Theagenes*. Forewing very thinly scaled in the disc, ochreous-brownish, towards the margin darkened with 2 or 3 minute subapical punctiform spots. Hindwing in the disc whitish, at the margins blackish-brown. Beneath coloured and marked the same, though of a much duller colour. As its patria only South America is mentioned.

49. Genus: **Theagenes** *G. u. S.*

Chiefly distinguished from the preceding genus by a still more convex costal margin of the forewing exhibiting a slight concavity before the apex. The ♂ has a costal fold. Hindwing in some species rather strongly dentate, in *diurna* even extended into long points. More than half a dozen species distributed over Central and South America.

- aegides*. **Th. aegides** *H.-Schäff.* (177 e) is above greyish-brownish, in some places mixed with bluish-grey, with numerous darker transverse lines and 2 apical dots. Disc of hindwing white. Beneath the forewing is for the greatest part yellowish-or orange-brown, the white hindwing especially towards the margin brownish and watered bluish. From Mexico through the whole of Central America to Colombia.
- albiplaga*. **Th. albiplaga** *Fldr.* (177 e) is somewhat larger, stronger, more densely scaled, more profusely mixed with bluish-grey, with but one subapical dot; the white spot of the hindwing is smaller, rounder, the base and proximal margin broader, darker. Beneath the hindwing is more intensely and more irregularly strewn, especially the costal margin is darker, too. Central America to Venezuela.

Th. lactifera *Btlr. & Drc.* (= *bipuncta* *Plötz*) (177 f). This well-known, common species is distinguished by greyish-brown forewings with a darkened base, two darker dentate transverse lines and 2 or 3 small white subapical spots; hindwing in the disc white, more or less smoky. Beneath on the forewing towards the margin yellowish lighter parts are predominant, on the hindwing more reddish-brown tints. Mexico to Colombia, rather variable. — f. **noctua** *Fldr.* (177 f) is lighter, the forewing in the disc spotted light, the white area of the hindwing much more extensive. As *noctua* is the older form, it ought to be the name of the species.

Th. stator *G. & S.* (177 f) is much darker than the preceding species, marked more irregularly, with very dark hindwings. Beneath on the lighter brown ground on the hindwing towards the costal margin intermixed with small red spots. Mexico to Colombia.

Th. haematospila *Fldr.* (177 f) is very similar, more intensely marked and easily discernible by much more prominent scarlet spots beneath also at the apex of the forewing. Venezuela, Colombia, Bolivia.

Th. diurna *Btlr.* (177 f). Unmistakable by the hindwing being extended on the median veins into 2 long pointed dents. The total tint is more brownish, above otherwise marked similarly as *stator*. Beneath the anal half of the hindwing is whitish, the costal part brown and spotted orange-yellow. Brazil.

50. Genus: **Miltomiges** *Mab.*

This genus established for the only species is distinguished by long antennae with a long, turned down point; palpi long porrect. On the forewing the upper radial vein rises below the upper cell-angle, the middle radial vein nearer at the lower. Hindwing rounded, before the anal angle slightly concave. The posterior tibiae are provided with fringes on the outside and exhibit 2 pair of spurs.

M. cinnamomea *Fldr.* (= *haematites* *Mab.*, *depuncta* *Plötz*) (178 b) looks above like a *Cobalus* and is uni-coloured deep blackish-brown. The under surface is yellowish-red, strewn with cinnamon-brown, in the interior of the forewing darker brown, towards the proximal angle light grey, towards the apex more yellowish with distinct dark veins. Hindwing with a broad, dentate, dark brown transverse band and dark anal stripe. Colombia and Brazil.

51. Genus: **Scantilla** *G. u. S.*

This genus likewise based on but one species is very closely allied to *Staphylus* p. 904 to 6, from which it differs by the absent costal fold, a stouter, shorter and more obtuse antennal club and a longer 3rd palpal joint being turned forward and downward.

S. opites *G. & S.* (177 g) is coloured and marked as the species of *Staphylus*, dark brown with 2 indistinct, faded transverse bands; no subapical dots. The under surface is strewn with dark ochreous, the palpi are below white. From Guatemala.

52. Genus: **Paramimus** *Hbn.*

Distinguished by long forewings with a short distal margin without a costal fold. The antennae exhibit a long, uniformly bent club; palpi thickly scaled white, from which the long black terminal joint projects. The posterior tibiae are not thickened and exhibit a hair-tuft and 2 pair of spurs.

P. stigma *Fldr.* (177 h) has blackish-brown wings with 2 large, white, transparent spots, in an oblique light with a silvery lustre, behind the cell of the forewing, below it a red spot. The hindwing shows a white median band not reaching the costal margin. Beneath paler, the hindwing as far as the base white, at the anal angle spotted white. Panama to Colombia.

P. scurra *Hbn.* (177 h) is very similar; whereas in *stigma* the proximal white spot is situated above the red one, it is longer here, crescentiform and passes the red one outwardly. Beneath the anal angle is not spotted white. Brazil. — In f. **leucodesma** *Er.* (177 h) from Guiana the red inner-marginal spot is entirely absent.

P. herberti *G. & S.* is likewise similar, the lower white hyaline spot of the forewing, however, is very irregular, not square and extends into the cell. Described from Matto Grosso.

P. monostigma *G. & S.* is likewise allied, the forewing, however, is dark brown, and only the red spot is present, the two hyaline spots being entirely absent. Santa Martha.

P. empolaeus *Dbl. & Hew.* (177 g) is a somewhat larger species with 2 reddish-yellow spots in the middle of the costal margin and at the proximal angle of the forewing, and a white spot between them. The hindwing shows a more rounded creamy-white discal spot. From Brazil.

alaricus. **P. alaricus** Plötz (178 a) is likewise larger, without red spots, with three small subapical spots situate in a triangle, an oblong quadrangular spot in the cell, a small one above it and a somewhat larger one below it. From Bahia.

53. Genus: **Charidia** Mab.

Distinguished from the preceding merely by the thickened posterior tibiae and a shorter palpal terminal joint. Only one sexually dimorphous species.

lucaria. **Ch. lucaria** Hew. (177 g). This pretty, little species is well characterized by the figure. Guiana, Colombia, Bolivia.

54. Genus: **Atarnes** G. u. S.

Likewise similar to a *Paramimus*. The antennal club is longer with an obtuse apex; the 3rd palpal joint is short. The ♂ is without a costal fold. The posterior tibiae show 2 pair of spurs, but no hair-pencil. Only 2 very similar species:

sallei. **A. sallei** Fldr. (177 g) from Mexico to Costa Rica is a common, unmistakable species, black with a white median band forming on the lower radial vein an almost rectangular angle, and an orange-yellow spot therein at the proximal margin below the cell; in the marginal area the veins and folds are striped white.

servatius. **A. servatius** Plötz (177 g) is extremely similar, larger, darker, the veins of the marginal area very much finer, the white median band projects distally on the upper median vein and does not reach the proximal margin on the hindwing. From Pará.

55. Genus: **Zopyrion** S. u. G.

Very closely allied to the following genus *Timochreon* and distinguished by its more slender structure, longer though rounder wings. Antennal club is more abruptly flaved, the 3rd palpal joint longer; costal fold present in the ♂.

sandace. **Z. sandace** G. & S. (177 h). Upper surface monotonously greyish-brown with single small light dots. Fringes light yellowish-white, speckled dark. Beneath almost whitish, hindwing still lighter, watered brownish with 2 more distinctly prominent transverse lines which are more or less interrupted, and with an antemarginal row of crescents. Mexico to Guatemala.

evenor. **Z. evenor** G. & S. (178 b) is above very similar, but beneath more ochreous-yellow on the forewing with 2 indistinct, dark, antemarginal macular bands; hindwing likewise more brownish, the transverse markings much less coherent, the proximal one only consisting of 3 small spots. From Matto Grosso to Argentina (Salta).

satyrina. **Z. satyrina** Fldr. (177 h) is beneath quite similar to *evenor* in the colour, but the hindwing shows before the whitish distal margin high black moon-spots, in front of them the white marginal colour is separated from the brownish ground-colour by a darker shaded lunular line; the centre is crossed by an almost straight line from the costal angle to the proximal angle. Colombia.

56. Genus: **Timochreon** G. u. S.

Structure of the body rather robust. Antennal club only feebly thickened and gradually bent; 3rd palpal joint rather short. Apex of forewing pointed, costal fold absent. The posterior tibiae with 2 spurs and in the ♂ with a long hair-pencil.

satyrus. **T. satyrus** Fldr. (177 i) is above dark brown with a row of black spots before the distal margin of the hindwing and 2 indistinct lines before it. Beneath entirely resembling an *Euptychia*: greyish-brownish, distally somewhat more bluish, with 2 brownish postmedian transverse bands bordered darker, and before the black marginal line of the hindwing a series of black eye-spots, of which only the second from above is dull brownish. From Panama to South Brazil (Para, Matto Grosso).

doria. **T. doria** Plötz (178 b) is another species still more resembling *Euptychia*: above duller brown, the eye-spots of the hindwing more distinctly light-ringed, the second from above composed of 2 small, narrow spots. Beneath the disc of the forewing is light ferruginous-yellow; the marginal area light reddish-violet, proximal bordered by a whitish line. Eye-spots of hindwings ringed light yellow. From Mexico.

57. Genus: **Pholisora** Scdd.

Antennal club almost rectangularly flaved with an obtuse apex. Terminal joint of palpus slender projecting. Costal fold present; apex of forewing very round. Posterior tibiae with 2 pair of spurs.

catullus. **Ph. catullus** F. (177 h) is on both sides black with a faint marginal row and a somewhat more intense submarginal row of white dots; the latter is entirely absent on the hindwing. Beneath the dots are almost extinct.

The green larva with a black head lives on *Chenopodium*, *Amaranthus* and Labiates such as *Monarda*; it spins a leaf together with few threads in a cymbiform shape and feeds only at night. Common in the whole temperate North America.

Ph. mejicanus *Reak.* (177 h) is similar, the submarginal row of spots, however, is very much curved, and at the cell-end there is a minute white dot. In the ♀ the small spots are somewhat larger. Beneath there are mostly only 3 or 4 subapical dots; the colour is particularly on the hindwing lustrous slate-coloured black with darker veins. Palpi beneath white. Distributed from the south-western part of North America to Mexico.

Ph. smodora *Dyar* (177 i) is much larger with broader, rounder wings, with a somewhat browner tint; only the curved, submarginal row of spots and a tiny cellular dot are present. Beneath more brown, without markings, only on the hindwing there are towards the anal angle some small white scale-spots. The whole body is beneath white. West Mexico (Guerrero).

Ph. clytius *G. & S.* is smaller than *mejicanus*, the wings without any spots, the hindwing in the middle of the distal margin more produced. The different genitals prove the insect to be a separate species. From Mexico.

Ph. alpheus *Edw.* (177 i). Wings above blackish-brown, mixed with a somewhat lighter colour; on the forewing there are 3 subapical dots, a discal dot and between the median veins a whitish submarginal streak. Hindwings darker. The under surface is deep dark brown, on the hindwing scantily strewn with white irregularly marked. Palpi beneath whitish. From New Mexico and Arizona to Mexico.

Ph. libya *Seddr.* (177 i) is easily discernible from the other species by white fringes, and towards the apex especially in the ♀ a lighter, grey apex of the forewing. Hindwing beneath light grey mixed with a darker shade, with white discal spots and minute white marginal spots. Nevada to Arizona and California.

58. Genus: **Chiomara** *G. & S.*

Palpal terminal joint porrect or somewhat pendent; antennal club comparatively obtuse. Distal margin of forewing convex. Posterior tibiae with a rather dense fur, a hair-pencil and 2 pair of spurs.

Ch. mithrax *Mschlr.* (= *noctula* *Plötz*) (177 i). This well-known species is of a deep blackish-brown with a slaty-black, broad discal area, proximally bordered by a row of velvety black dots; a similar row of spots is situate farther distally. Beneath lighter brown, with a darkened basal part on all the wings. Mexico, Guatemala, Colombia to Brazil, Cuba.

Ch. punctum *Mab.* (= *basigutta* *Plötz*, *marthona* *Schs.*) (177 i) is very similar, mostly smaller, distinguished by a lighter bluish-grey, prominent postdiscal band and a very prominent black spot in the proximal third of the proximal margin. Widely distributed in South America.

Ch. silvia *Mab.* Size and exterior of *punctum*. Forewing blackish mixed with ashy-grey; near the base a broad, lilac-grey band with a thick, black dot in the submedian space; the following black band is pointedly broken in the cell, then follows a broad greyish-lilac band traversed by 2 black stripes; the black marginal area is crossed by a greyish-red dentate line. The red-brown hindwing shows 3 darker undulate lines. Beneath the forewing is proximally black, in the marginal third light red-brown with a lilac apical spot. Hindwing black, distal margin red-brown, with a black cellular spot and 2 black median bands, the proximal one of which is bordered with yellowish at the anal angle. Described from Bolivia.

Ch. gesta *H.-Schäff.* (= *blanda* *Plötz*, *invisus* *Btlr. & Drc.*) (178 a) is a smaller, variable, darker species, blackish-brown with indistinct darker transverse bands and a dull bluish-grey postdiscal band. Occasionally there are on the hindwing beneath whitish diffuse spots towards the anal part. From Mexico to South Brazil, in Cuba and Jamaica. — f. **gorgona** *Plötz* (178 a) is a lighter brown form from Guatemala with reduced black spots and bands. — f. **bigutta** *Prittiv.* (177 i, 178 a) with a somewhat different band-marking, distinctly speckled fringes of the hindwing, and beneath towards the anal angle with lighter whitish hindwings; it may be better regarded as a distinct species; described from Colombia.

Ch. asychis *Cr.* (= *dilucida* *Plötz*) (178 a) is a very different, extremely common species and very variable. Above greyish-brown, towards the base bluish-grey with a broad hyaline band through both wings; the uppermost spot of the band on the hindwing is bipartite; here there is in the cell another narrow, crescentiform spot, and there are lighter antemarginal macular bands. Widely distributed from Mexico to Argentina, and in the Antilles; specimens from St. Vincent are darker with more distinct spots on the wings beneath.

Ch. onorbo *Möschlr.* (178 a) very much recalls *asychis* which it also resembles a great deal in its size and shape of the wings. But beneath *onorbo* shows the basal area of the hindwing bluish-grey and sharply defined against the white discal band from which it is separated by a dark line, just like the dark marginal area. Above particularly the speckled marking of the distal half of the forewing deviates from *asychis*. Described from Surinam.

59. Genus: **Gindanes** *G. u. S.*

In the structure and exterior similar to the species of *Pythonides* of the *lugubris*-group and chiefly only distinguished by the peculiar shape of the wings. The apex of the forewing is cut off and the distal margin straightly extends down to the end of the lower median vein, where it is deeply indented and runs obliquely to the proximal angle; hindwing below the apex almost laciniformly produced. The posterior tibiae exhibit beside a hair-pencil 2 pair of spurs. Antennal apex somewhat longer and palpal terminal joint shorter.

brebisson. **G. brebisson** *Latr.* (= *brebissonii* *Ky.*, *phagaesia* *Hew.*) (178 c) is above light brown with a deep brown velvety spot in the middle of the forewing and smaller ones behind it, at the proximal angle of the forewing and at the apex of the hindwing the distal margin of which, being situate below it, is dusted bluish-white. The forewing exhibits besides at the exterior edge of the discal spot one large and several small hyaline spots. Beneath the hindwing is light blue, at the costal margin and apex spotted somewhat blackish-brown. From Colombia and Brazil.

panaetius. **G. panaetius** *G. & S.* (178 c) is probably only the northern form of the preceding and merely distinguished by the ochreous-yellow, not blue under-surface of the hindwing, only the anal part being somewhat dusted bluish-white. From Nicaragua and Panama.

brontinus. **G. brontinus** *G. & S.* (178 c) is of a much darker brownish-grey, the hyaline spots are much more reduced, and the dark discal spot is narrowed into a streak; instead of them there is a broad, dark antemarginal band. Under surface dark brownish-grey. Apparently only in Nicaragua.

extensa. **G. extensa** *Mab.* It is doubtful to me, whether this species being described as *Pterygospidea* belongs hereto. The wings are described to be yellowish-grey, forewing at the proximal angle deeply excised. Margin brown, proximally dentate. 3 subapical hyaline dots in a brown band, between the upper median vein and the middle radial vein a bipartite hyaline spot and below it a similar one in the submedian space; at the lower cell-angle there is another hyaline dot in a brown spot. Hindwing below the apex very much gnawed out, at the middle radial vein with a long booth with 3 faint, brown, small bands. Wings beneath light blue, the darkest at the base of the hindwing with a black border as far as the tooth. Expanse of wings: 27 mm. Hunyabamba.

60. Genus: **Heliopetes** *Billb.*

It contains a number of rather homogeneous insects offering great difficulties as to the synonymy. All of them are above more or less purely white, mostly with a black apex of the forewing. The medium-strong antennal club is bent, the palpi are porrect, the 2nd joint covered with hairy scales, the terminal joint rather slender, conical. Costal fold present; posterior tibiae beside two pair of spurs with a hair-pencil.

domicella. **H. domicella** *Erichs.* (= *willi* *Plötz*, *aconyta* *Plötz*, *adepta* *Plötz*) (178 c) is the darkest species with a broadly blackened basal and distal part of the wings, so that only a broad white discal band is prominent and the species almost looks like a *Hesperia*. Beneath similar, but duller, more olive-grey, particularly the basal part of the hindwing is light and only defined towards the white discal band by an olive-grey band pointedly bending inward in the cell towards the base. From Arizona and Mexico through almost the whole of South America (Colombia, Guiana, Brazil to Argentina).

arsalte. **H. arsalte** *L.* (178 c, d) is almost entirely white, only towards the apex along the ends of the veins on the forewing there appear black rays; fringes speckled dark; in the ♀ the apex of the wing is somewhat more extensively smoked blackish, with a white, oblique subapical band. Beneath the veins are finely darker, on the hindwing the lower median vein is somewhat darker. Widely distributed from Mexico to Paraguay and in Jamaica, everywhere very common.

petrus. **H. petrus** *Hbn.* (= *niveus* *Hbn.*, *laginia* *Hew.*, *bianca* *Plötz*, *janice* *Ehrm.*) (178 d) differs by a much broader and blacker apex of the forewing with a smoked subapical band in it; the margin of the hindwing is likewise broader black. From the following *alana* it differs by the absence of the dark spots in the middle of the hindwing beneath. From Nicaragua through Colombia, Guiana to the Amazon.

alana. **H. alana** *Reak.* (= *adusta* *Plötz*) (178 d) resembles *petrus* above. Beneath on the ochreous-brown hindwing behind the cell and before the margin between the median and subcostal veins more or less distinct brownish spots. From Mexico to Brazil and Paraguay, everywhere common. — As f. **ligania** (178 e) *Plötz* figures a large, strong form with a very broadly blackened apex of the forewing without a light subapical band and beneath only one spot between the median veins of the hindwing, no patria being stated. — f. **marginalis** *Plötz* (178 d) from Peru is probably a form of it with a broadly blackened margin of the hindwing.

nivella. **H. nivella** *Mab.* (= *nivea* *Scddr.* nec *niveus* *Hbn.*, *orbiger* *Mab.*, *eulalia* *Plötz*) (178 d) has above a narrowly blackened distal margin growing wider in the apex of the wing with traces of subapical spots, one

of which projects above the upper radial vein to the margin; on the hindwing there are before the fine black marginal line small dark spots on the ends of the veins. Beneath the hindwing shows a rather broad black marginal band which is interrupted by white below the upper radial vein; near the base there are yet some dark diffuse spots. Mexico to Colombia and Brazil. — **maimon** Plötz (178 e) is probably a small, above entirely white form of it from Guiana.

H. macaira Reak. (= *oceanus* Edw., *locutia* Hew.) (178 e) is smaller, above the same, beneath the hindwing is smoked brownish except the anal part, the marginal band is not interrupted and distally extending in a coppery brown, the basal spots are larger. Arizona to Panama. — f. **jason** Ehrm. is a pale, thinly scaled form from Venezuela with beneath extinct basal markings, of a slender structure.

H. cnemus G. & S. (178 e) is above much more intensely marked with broad blackish-brown marginal bands; in the broad apex of the forewing there are 4 or 5 small, narrow, white subapical spots. Beneath almost like *nivella*, but the apical part of the forewing is more broadly marked black, whereas the marginal band of the hindwing is feebler. Only from Mexico.

H. laviana Hew. (= *leca* Btlr.) (178 e) is mostly rather large with a faintly stunted, broadly blackened apex of the wing, with subapical, apical and marginal white spots. Beneath in the apex of the forewing 2 larger, olive-brown spots. Hindwing more or less extensively dusted olive yellowish-grey, with a broad, dark, basal transverse band which in the cell returns to the base in an acute angle, and a broadly darkened marginal part proximally bordered by an almost straight, darker, inside white line extending from the costal angle to the anal angle. The development of the marking, however, is very variable. Mexico to Argentina, everywhere very common. — f. **ericetorum** Bsd. (178 f) is a very light form from California.

H. sublinea Schs. is unknown to me, but it apparently approximates *laviana* very much; distinguished by a black cell-end streak and white fringes speckled with black, as well as more distinctly black veins in the apical half also beneath. Hindwing of a purer white with a broad olive-grey marginal part, a dark apical spot and a darker marginal band below the lower radial vein; the broad, proximal olive-grey band extends from the costal margin to the lower median vein. Expanse of wings: 33 mm. Described from Mexico (Orizaba).

H. purgia Schs. must be likewise similar to *laviana* (178 e); above marked just like it, but below the lower radial vein there appears a larger, white marginal spot. Fringes dark grey. On the hindwing the veins are partly black, beside a black marginal line and black marginal lunae there is a subterminal line interrupted between the radial veins; base, and proximal margin of the hindwing dusted black. Fringes of hindwings white speckled with black. Beneath marked light reddish-grey, forewing with a black cell-end streak; hindwing yellowish-white with black veins, a broader and darker subterminal band; the proximal band as in *laviana*, the inner-marginal area remains broadly white, unmarked. Expanse of wings: 30 mm. Castro (Paraná).

H. pastor Fldr. (= *omrina* Btlr.) (178 f). I consider to be a distinct species; smaller than *laviana*, without traces of a stunted apex of the wing; owing to the more distinctly marked veins the dark marginal area looks striped. Marginal part of the hindwing more intensely marked. Beneath of a purer white, markings in the marginal part likewise more radiately arranged and with a decidedly yellowish-green tint: basal band feebler, in the middle interrupted. Guiana to Brazil. — In Bolivia there occurs a still much more intensely marked form which I denominate **intensa** form. nov. (178 f). Above particularly on the hindwing in the costal half there appears a postdiscal band angularly projecting distally and being also present beneath; the subbasal band is deep olive-brown and complete. — f. **pampina** Plötz (178 f) from Buenos Ayres, in contrast with it, is much lighter, above much more extensively white, and beneath on the hindwing only the basal band is rudimentarily noticed.

H. leucola Hew. (178 f). I dare not decide whether this is a distinct species or only an intensely marked form of *petrus* (178 d) from which it is not discernible above, whilst beneath the hindwing is of a more intense yellow colour with prominently black veins and internerval stripes, without any dark antemarginal spots. From Minas Geraes.

H. concinnata Mab. seems to be allied to *laviana* (178 e); distal margin of wings more intensely marked black with small, white submarginal and very small marginal spots which are absent between the median veins. On the hindwing beneath the upper part of the basal band is absent. Described from Rio Grande do Sul.

H. figara Btlr. Wings above white, forewing at the base, costal margin, apex and distal margin brown; an apical, white oblique line is parted into 5 dots by the veins crossing it. Hindwing at the proximal and distal margins brown, veins (except the base of the costa) black, fringes white speckled with brown. Body brown, head and prothorax spotted white. Wings beneath white, veins in the distal half black; apex between the veins white. Otherwise as above, but lighter. Body white. 1.6 inch. Exact patria not stated.

61. Genus: **Thanaos** Bsd.

Rather closely allied to the preceding genus; the basal palpal joints are clad with long hair, the conical terminal joint is bent forward. Costal fold very strongly developed. Hindwing in the basal quarter of its costal

margin somewhat angular, the fringed posterior tibiae exhibit 2 pair of spurs. Numerous species of a very dark colouring in contrast with the preceding genus, the principal range of which is situate in North America.

- brizo.* **Th. brizo** *Bsd. & Lec.* (178 f). Above lilac-grey with darker macular bands, the postdiscal band very regularly formed of small ring-spots, appearing also beneath as minute light yellow spots. Hindwing with a row of yellowish submarginal dots being more distinct beneath. Atlantic States, Colorado, Arizona. The larva lives on oaks, Galactia and Baptisia.
- icelus.* **Th. icelus** *Lintn.* (178 g) is much smaller, the postdiscal area much lighter than the rest of the wing; the yellowish dots above and beneath do not form any regular rows, but are more dispersed. The range is the same. The larva lives on foliage-trees.
- somnus.* **Th. somnus** *Lintn.* (178 g) is somewhat larger than *icelus* and a very dark species so that only the submarginal row of light dots is more distinct. From Florida.‡
- lucilius.* **Th. lucilius** *Lintn.* (178 g) is a smaller, very common species, blackish-brown with darker macular bands and minute light submarginal spots; discernible from the very closely allied *pacuvius* (178 h) by its lighter, dark-marked hindwing with a submarginal band of light spots, in which near the apex 2 spots are far removed towards the base. The likewise very closely allied *zarucco* has much more intense purple-grey dusting on the wings and more regular macular bands on the forewing. Atlantic States. — f. *lilius* *Dyar* is very similar, larger, as large as *zarucco*, more mixed with brown, particularly a brown spot at the cell-end is very prominent, being interrupted by the straight, dark cell-end line. The markings are more blurred and not so much contrasting as in *zarucco*. A geographical race from British Columbia, Washington, California. Flies in May, June, and again in August.
- persius.* **Th. persius** *Seddr.* (178 g) is much more monotonous and mostly darker than *lucilius*, but very variable in this respect. Apex of forewing a little more pointed than usually with 3 distinctly prominent, small subapical spots. The hindwing scarcely shows traces of the light submarginal dots. Atlantic States and Rocky Mountains. Larva on willows.
- ausonius.* **Th. ausonius** *Lintn.* is the smallest of all the *Thanaos*-species; by the absence of the white subapical spots it approximates *brizo*, otherwise it is more closely allied to *zarucco*. The submarginal band composed of small, oblong, black spots is twice very much bent. The transverse vein is conspicuously marked brown. Instead of the discal band being coherent in the other species there are here 3 small, oblong, blackish-brown diffuse spots. The species was established according to a single ♂ from Center (Colorado) that was taken on May 12th 1871.
- afranius.* **Th. afranius** *Lintn.* (178 g) is a very small species with a blackish-brown, grey-marbled forewing showing 4 small, oblique subapical dots and one behind the cell. Hindwing dark blackish-brown with a double row of small submarginal dots being above very indistinct, beneath more prominent. Colorado, Arizona.
- zarucco.* **Th. zarucco** *Luc.* (= *martialis* *Seddr.*) (178 g) very much resembles *lucilius*, but it is much more dusted with a purple or lilac-grey, and thereby lighter, and the macular bands are more regularly arranged. The submarginal spots on the hindwing are more irregular and more blurred. Atlantic States, Colorado, also in Cuba. The larva lives on Indigofera and Amaranthus.
- juvenalis.* **Th. juvenalis** *F.* (= *juvenis* *Hbn.*, *costalis* *Dbl. & Hew.*, *ennius* *Seddr.*, *concolor* *H.-Schöff.*) (178 g). A much larger species, light brown, marbled by black macular bands and with a complete, postdiscal row of small hyaline spots bordered by small black sagittiform spots; also at the cell-end there are two. Atlantic States and Rocky Mountains as far as Missouri and New Mexico. The larva lives very polyphagous on oaks and Papilionaceae.
- petronius.* **Th. petronius** *Lintn.* (178 g) is similar, especially in the basal half darker, more contrasting; the band of hyaline spots does not extend so far to the proximal margin. The hindwings are also much darker. Florida.
- horatius.* **Th. horatius** *Seddr.* (= *virgilius* *Seddr.*) (178 h). Marked as *juvenalis* and with the same band of hyaline spots, but only half its size, and of a very much lighter ground-colour. From the southern Atlantic States.
- terentius.* **Th. terentius** *Seddr.* (= *ovidius* *Seddr.*). Of this species we find in the literature accessible to us only a very detailed description of the ♂ genital armature, and for this reason we cannot make any particular statements as to its exterior. It originates from Florida.
- propertius.* **Th. propertius** *Lintn.* (178 h) is likewise somewhat smaller than *juvenalis*, very much like it, darker, greyer, more monotonous, the small postdiscal hyaline spots very small. Owing to the distal margin running somewhat more obliquely, the course of the band is more oblique, too. Hindwings darker. Pacific States.

Th. naevius *Lintn.* (178 h) is smaller, with narrower and more pointed wings than *petronius* which the species approximates; the postdiscal hyaline band is likewise shortened and also contains only 2 discal spots below the subapical band. Behind the middle of the costal margin lighter spots. Only known from Florida. *naevius.*

Th. pacuvius *Lintn.* (178 h) is much smaller, very contrastingly marked on a grey ground, the small hyaline spots of the postdiscal band, being formed as in the preceding species, are very small. Hindwing almost entirely black, its fringes in the anal half purely white. Colorado, Arizona and Mexico. *pacuvius.*

Th. tatus *Edw.* is established according to a single ♂. It is discernible from the other species with white fringes of the hindwings by the purely brown colour of the marginal area of the forewing without whitish-grey scaling; the usual, oblong, black marginal spots exhibit distally bluish-white bordering, so that a very conspicuous, white-dentate line is produced. From Arizona. *tatus.*

Th. parkeri *Weeks* is said to be most closely allied to *tatus*. Above dark brown, slightly dusted with grey, with a postdiscal band irregularly strewn with grey, extending from the costal margin to the lower median vein; 4 small, white, hyaline subapical dots. Hindwings dark brown with traces of lighter submarginal diffuse spots. Beneath dull brown, the submarginal diffuse spots of the hindwing more distinct. From Venezuela (Suapure). *parkeri.*

Th. clitus *Edw.* (178 h) is much larger and darker than *pacuvius*, often behind the middle of the costal margin with a brighter spot. Hindwing almost monotonously black with broad white fringes as far as the apex. Arizona and New Mexico. *clitus.*

Th. funeralis *Seddr.* (= *australis* *Mab.*) (178 h). This species being widely distributed as far as South America is extraordinarily similar to *clitus*, on an average smaller, greyer, darker, with somewhat narrower forewings. The following species are neither easily discernible, chiefly by the difference of the genitals. In *funeralis* the tegumen exhibits on the under surface 2 short, downwards posteriorly curved hooks; the valves are very asymmetrical, the right one has undulate edges and exhibits on its distal edge 2 upturned, obtuse appendages. From California, Texas and Arizona through Mexico to Guatemala; Colombia. *funeralis.*

Th. tristis *Bsd.* is externally scarcely discernible from *funeralis*, mostly somewhat larger. The forewings are somewhat less pointed. On the under surface of the tegumen are 2 long hooks being downwards anteriorly curved, the right valve shows at its distal edge a very bristly, boss-shaped appendage. California to Mexico. *tristis.*

Th. maestus *G. & S.* from Arizona and Mexico (Puebla) is only separable by the different genitals. The tegumen is similar as in *tristis*, but the right valve appears as a distally turned, ensiform hook. *maestus.*

Th. albomarginatus *G. & S.* (178 h) is recognizable by its large size and by the white fringes of the hindwing being particularly broad at the anal angle, beneath also by the white border before the fringes. Common from Mexico to Colombia. *albomarginatus.*

Th. diogenes *Plötz* (178 i) is the most similar to *petronius* (178 g), but somewhat smaller, with narrower wings and a more oblique distal margin, of a somewhat darker colouring, the postdiscal hyaline spots are minute, below the subapical ones there is only one small hyaline dot. Described from Cuba. *diogenes.*

Th. heteropterus *Plötz* (178 i) is not dissimilar to *brizo*, but of a purer bluish-grey, and it has 3 conspicuous, white, subapical hyaline dots. Hindwing darker brown without the yellowish submarginal dots, instead of them with a darker submarginal band. From Brazil (Chapada). *heteropterus.*

Th. austerus *Schs.* is unknown to me. Above dark brown, strewn with dark grey, little prominent scales, a discal band, a spot at the cell-end, bent round it the postdiscal band; distal margin broad dark grey, in it a dark subterminal line; marginal line brown, base of fringes grey; the grey markings are partly bordered by darker brown fine lines. The dark brown hindwing is lighter at the distal margin. Expanse of wings: 36 mm. Peru. *austerus.*

Th. mülleri *sp. nov.* (178 i) is most similar to *brizo*, also in the shape of the wings and the size. The blackish-brown ground-colour is very much strewn with lighter or darker whitish-grey or bluish-grey scales; in and behind the middle there are 3 fine, black, lunar transverse lines and in the middle of the cell a spot; before the brownish-grey fringes there is a blackish marginal line. Hyaline dots entirely absent. Hindwing monotonously blackish-brown with snow-white fringes being blackened at the apex. Beneath on the hindwing fine, white anteterminal and thicker white terminal dots. According to 1 ♂ from Mexico (Esperanza) in the Coll. DRAUDT. *mülleri.*

Th. lacustra *Wright* (178 i) is apparently allied to *mülleri*, but of a much more monotonous brownish-grey, not dusted so blue, and it has quite brownish-grey, not white fringes on the hindwings. Also beneath the submarginal and marginal dots on the hindwing are extinct and yellowish-grey. From California. — **pernigra** *Wright*, likewise from California, seems to be almost the same, but it is reported to have 3 small white subapical dots and to be smaller. *lacustra.* *pernigra.*

62. Genus: *Melanthes* *Mab.*

Antennal club shorter and more pointed than in *Thanaos*, terminal joint of the palp more slender. Distal and proximal margins broadly rounded. Posterior tibiae almost bare with 2 pair of long spurs. Costal fold present. 3 large forms from the West Indies.

brunnea. **M. brunnea** H.-Schüff. is extremely allied to the following, it is smaller with smaller hyaline spots.
jamaicensis. Described from Cuba. — f. **jamaicensis** Mschlr. (178 i) is probably only a local form from Jamaica. Large, monotonously blackish-brown above and beneath with 3 minute subapical dots and 2 more near the margin below them.

zephodes. **M. zephodes** Hbn. (178 i) has nothing to do with *Ephyriades otreus* Cr. as was erroneously considered hitherto. Very similar to the preceding, somewhat smaller, and with narrower wings, blackish-brown with 5 minute, white subapical dots and 2 more proximally placed dots below them, and another one in the upper cell-angle. Beneath somewhat lighter with traces of darker transverse bands across the hindwing. The ♀ has much larger hyaline spots and 2 faded dark transverse bands before and in the middle, between which the ground is partly dusted bluish-grey. Cuba, Bahamas.

63. Genus: **Brachycoryne** Mab.

Antennal club with an obtuser end, shaft short, not curled. Costal fold very strongly fringed with long hair-scales, inside bare. The middle and posterior tibiae exhibit long slender hair-pencils, the posterior tibiae 2 pair of short spurs, the anterior tibiae with end-spurs. Only one species:

arcas. **B. arcas** Drury (= flyas Cr., velasquez Luc.) (178 i). Large, monotonously dark blackish-brown, above without any marking. Beneath somewhat lighter, at the proximal margin of the forewing yellowish-grey with traces of a darker postdiscal band. Hindwing with 2 antemarginal, faded, lighter, dentate bands. Panama (Chiriqui), Hayti, St. Thomas, Cuba.

64. Genus: **Hesperia** F.

This genus being distributed across the whole world except Australia has been dealt with more at large in the palearctic part. Briefly worded, the antennal club is rather obtuse, the palpi are erect, the second joint clad with hair-scales, the terminal joint slender, obliquely upturned. Forewing with or without a costal fold, posterior tibiae with 2 pair of spurs with or without hair-pencils. The homogeneousness of the American species is still very uncertain; there are probably half a dozen species at most.

a) With a costal fold and hair-pencil (*Scelothrix* Rmb.).

syrichtus. **H. syrichtus** F. (= orcus Cr., oileus Ww., tartarus Hbn.) (178 k) is extremely variable as most of the other species. Above brownish-grey verging into black, particularly towards the base very much haired whitish-grey with white macular bands covering more or less the whole surface of the wings. Beneath the hindwing is white with 2 irregular light grey or brownish dentate bands which are finely bordered with black, and with high marginal bows. Most widely distributed from Mexico to Paraguay, everywhere common.

centaureae. **H. centaureae** Rmb. (= wyandot Edw., ruralis Bsd.). This species figured in the palearctic part (Vol. I t. 86 a) occurs also in the northern Atlantic States. The white spots are much smaller than in *syrichtus*, the white hairing more scanty, beneath on the hindwing the bands are darker, more coherent.

philetas. **H. philetas** Edw. resembles *montivaga* (178 k) above, but it has smaller spots. The hindwing beneath is quite different white with a yellowish tint, basal and discal areas more whitish, without a discal band, scantily streaked brown; 3 small streak-spots at the costal margin are more distinct; behind the middle are 3 rows of most minute spots, the most proximal row only composed of small brown dots; in the smoky brownish marginal area minute, white moon-spots. Described according to a specimen from West Texas.

scriptura. **H. scriptura** Bsd. (178 k) is smaller than *centaureae*, the hindwing quite unspotted except a double white discal spot; fringes more purely white. On the forewing the submarginal macular band seems to be more pointedly broken below the apex. California, Arizona, Montana.

bocchoris. **H. bocchoris** Hew. The description of this Bolivian species was not accessible to us.

fulvovittatus. **H. fulvovittatus** Btlr. resembles above *americanus* (179 b) except the more strongly smoked discal band of the hindwing. Beneath the hindwing is white with 4 orange transverse bands, an indistinct one at the base, a very irregular, oblique one behind the basal third, a curved, dentate one through the middle, being here and there bordered with brown and being separated from a narrow marginal band only by a row of small, white moon-spots; proximal margin broad white. From Chile.

b) With a costal fold, but without a hair-pencil (*Pyrgus* Hbn.).

H. montivaga Reak. (= *tessellata* Seddr., *communis* Grt., *adjutrix* Plötz, *albescens* Plötz, *varus* Plötz) *montivaga*. (178 k) differs from the very similar *syrichtus* by a darker, less grey-haired base of the wings, and the marginal row of spots almost disappears. Distributed from Arizona and Florida to Nicaragua, everywhere common. f. **crisia** H.-Schüff. (178 k) is probably to be taken as a smaller insular form from Cuba with smaller spots, *crisia*. which are less coherent. — f. **occidentalis** from Arizona and Texas is reported to be smaller and whiter. *occidentalis*. It was asserted of late that *montivaga* is synonymous to *syrichtus*, in which case the species would have to be denominated *tessellata*.

H. caespitalis Bsd. (= *ricara* Edw., *petreus* Edw.) (178 k) looks very much like *centaureae*, on the *caespitalis*. hindwing the postdiscal band of white spots is broader and more coherent. Beneath the hindwing has a decidedly ferruginous-brownish tint with large white spots. California, Oregon, and Nevada.

H. xanthus Edw. (179 a) is extremely similar to *caespitalis*, the white macular bands still broader, *xanthus*. especially on the hindwing. Under surface much paler, almost as in *montivaga*. Hitherto only known from Colorado.

H. americanus Blch. (179 b) is a larger, stronger species from Chile; the white discal band of the *americanus*. hindwing is especially broad, fringes scarcely speckled. Beneath the hindwing is very differently marked, the bands are very narrow, very dentate, the proximal one defined on the lower median vein, the costal-marginal part almost straight and not dentate. — In f. **bellatrix** Plötz (178 b) from Argentina the bands of the hindwing *bellatrix*. beneath are broader, more coherent.

c) Without a costal fold and without a hair-pencil (*Battus* Scop.).

H. notata Blch. (= *insolatrix* Plötz, *lycurgus* Plötz) (179 a) is extremely similar to *syrichtus* and *notata*. *montivaga*, but the band of the hindwing is generally narrower, less curved. Very common from Mexico to Argentina. — f. **valdivianus** Phil. (179 b) is probably also only a form of it from Chile with a faded, smoky *valdivianus*. brownish band of the hindwing without the white discal spot. Beneath the surface is of a more yellowish tint, the transverse bands show a reddish-brown colour. — f. **veturius** Plötz (179 a) is presumably a form with much *veturius*. smaller white spots.

H. trisignatus Mab. (= *valdiviana* Reed) (179 a) is presumably no form of *notata*, but a distinct *trisignatus*. species. Above very dark owing to the great reduction of the white spots; on the hindwing a large, rounded, white discal spot is very conspicuous, besides there is only an antemarginal row of spots. Beneath very much dusted brownish, in the ♀ much more intensely transversely watered dark, with two interrupted, greyish-black nebulous bands in and behind the middle. Argentina and Chile.

H. emma Stgr. (179 a, b) is a rather large, broad-winged species, above black with 2 rows of white *emma*. spots in the middle and anteterminally; on the hindwing there is a large, square postmedian spot and a faded row of whitish dots before the distal margin. Fringes above and beneath white speckled with black. Beneath the forewing is blackish, at the costal margin and in the apical part light yellowish-white. Hindwing beneath pale yellow with 2 rows of larger black markings in the middle and in the distal part, and a number of small black strigiform spots at the costal margin and some small, dispersed dots. From Cocapata (La Paz in Bolivia).

H. cuzcona sp. nov. (179 a) may be a smaller form of *emma*. Shape of wings much narrower; above *cuzcona*. the white spots are a little more prominent, the wings towards the base more intensely haired whitish-grey, the fringes very broadly speckled white and black, the spot of the hindwing oblong quadrangular. Beneath almost purely white, forewing in the disc faintly dusted blackish; the transverse bands on the hindwing very narrow, composed of irregular, small, jet-black spots with single brownish grains of dust between them; fringes of hindwings beneath purely white, unspotted with thick black dots before them on the ends of the veins. From Peru (Cuzco).

H. archia Dyar is allied to *emma* (179 a, b). Above brown with yellowish-white fringes speckled with *archia*. brown, base and marginal area scaled yellowish; forewing with a quadrangular cell-spot and some more spots, like in *emma*. Hindwing with a yellowish strigiform spot at the cell-end and light dusting behind it and an antemarginal row of minute light spots. Forewing beneath as in *cuzcona*, hindwing light ochreous, strewn dark, with 2 rows of blackish, rounded quadrangular spots, as in *emma*. Peru.

65. Genus: **Celotes** G. n. S

Resembles the preceding genus, the antennal club is more slender. Costal fold present: the terminal joint of the palp is perfect, almost somewhat pendent. The posterior tibiae beside 2 pair of spurs exhibit a strong hair-pencil. Only one species:

C. nessus Edw. (= *notabilis* Streck., *radiatus* Plötz) (179 a) is distinguished from all the American *nessus*. species by the alternately light and dark radiary rays, and an unmistakable species. Texas to Mexico.

Subfamily: **Pamphilinae** Wts.

Group A.

Antennae with a bent, gradually tapering club. Terminal joint of the palp moderately long, correct. ♂ forewing in the American species without a stigma.

66. Genus: **Butleria** Ky.

This genus which was formerly combined with the following by the name of *Butleria* now only contains yet some species from South Chile of a characteristic exterior. Antennal club rather obtuse, palpi shorter, beneath hairy. Forewing at the base convex with an obtuse apex. Posterior tibiae with one or two pair of spurs.

bisexguttata. **B. bisexguttata** Phil. (179 c) is above blackish-brown with 6 minute orange spots which are in the ♀ partly larger and increased by two; the ♀ besides exhibits behind the cell of the hindwing a larger, roundish orange spot. Beneath the forewing is blackish, at the costal margin and apex red-brown as the hindwing, the latter with a broader, blackish discal shade and an undulate marginal band. It flies in dense forests in South Chile.

aperta. **B. aperta** Plötz (179 c) is allied to the preceding. Above dark blackish-brown with 3 small yellow discal spots arranged in a triangle, and 3 small subapical dots. Hindwing unmarked. Beneath the costal half of the forewing, the costal margin and the distal-marginal third of the hindwing are red-brown, on the hindwing 2 undulate, dark submarginal lines. Patria not stated.

valdivianus. **B. valdivianus** Phil. (= *exornatus* Fldr.) (179 c) is above much more intensely spotted yellow, especially in the submedian space, and the hindwing shows a submarginal row of yellow dots; fringes yellow. Beneath the forewing is yellow, spotted black, the hindwing more brownish-red with 3 transverse rows of silvery white spots partly bordered with black. Chile.

flavomaculata. **B. flavomaculata** Blch. (= *vicina* Reed., ? *paniscoides* Reed.) is a not quite certain species, it seems to be smaller than the preceding, but otherwise very much like it, easily discernible by yellow instead of silvery white spots beneath. Probably also *paniscoides* Blch. belongs hereto, the description of which is too insufficient as to allow its identification. Chile.

facetus. **B. facetus** Plötz (179 b) is allied to *flavomaculata*. Above black with numerous small yellow punctiform spots and a larger one at the cell-end. Hindwing with a light discal diffuse spot; fringes yellow speckled with black. Beneath the black, yellow-spotted forewing exhibits a reddish-yellow costal margin and distal margin. Hindwing reddish yellowish-brown with a large trisected, Isabel-coloured spot in the inner-marginal area, 2 small ones in the basal area and one at the costal margin above them. From Argentina and Chile.

polyspilus. **B. polyspilus** Fldr. (179 b, c) is again difficult to identify. It is somewhat larger, blacker, the discal spot of the hindwing larger, fringes of a purer yellow. Hindwing beneath lighter reddish-yellow, without any black markings, so that the white spots are situate directly on the reddish ground. This species, according to ELWES, flies more on open grass-plots in Argentina and Chile.

paniscoides. **B. paniscoides** Blch. (= *cauquenensis* Reed.) is a doubtful species which, as was mentioned above, probably is synonymous with *flavomaculata*, or perhaps also belongs to *facetus*, both of which exhibit yellow instead of silvery white spots on the hindwing beneath. Stated from Chile.

fruticolens. **B. fruticolens** Btlr. (= *tripunctatus* Mab.) (179 c) is a somewhat larger, most variable species. Above black, on the forewing with 4 to 9, on the hindwing with 2 to 4 small orange spots. Beneath the forewing is blackish, at the costal margin and apex reddish-yellow with the spots of the upper surface; hindwing orange, in the disc lighter yellow, at the proximal margin blackish, between the two colours a whitish ray. The forms denominated by BUTLER: *tractipennis*, *quadrinotatus* and *pulcher* only differ by the number of the small yellow spots. Chile, rising up to 4000 ft., and varying according to ELWES more in the maritime districts than in the mountains.

philippii. **B. philippii** Btlr. is very closely allied to *fruticolens*, differing only by a silvery stripe on the hindwing beneath. Apparently rare and hitherto only found in the Province of Valdivia.

ritus. **B. ritus** Plötz (179 c) is likewise closely allied, considerably larger with much larger yellow spots and two silvery stripes on the hindwing beneath with 3 silvery spots between. Hindwing much darker, only at the costal margin slightly yellow. From Chile.

sotoi. **B. sotoi** Reed. is likewise a very rare species very closely allied to the preceding. It differs by the bases of all the wings being strewn with yellowish, and a silvery white spot on the hindwing beneath. From South Chile, flying in dense forests.

67. Genus: **Dalla** Mab.

Antennal club with a longer point than in the preceding genera, palpi somewhat longer, especially the terminal joint slender. Forewing at the base not so convex. Posterior tibiae fringed with 2 pair of spurs. Numerous species mostly marked black and reddish-yellow.

D. cypselus *Fldr.* (179 c, d) is above blackish-brown with 4 yellowish-white discal spots on the forewing and 3 small subapical dots; of the former a small one is in the cell-end, 2 larger, separated ones below it and the 4th outside of them somewhat below the apical dots. Hindwing with an oval, somewhat reniform, orange discal spot, and towards the anal angle with orange fringes. Beneath more chestnut-coloured, the submedian spots of the forewing broadly united, towards the proximal margin of a deeper yellow; at the anal angle of the hindwing only a minute yellow diffuse spot. Colombia. *cypselus.*

D. frater *Mab.* (= *mesoxantha* *Plötz*) (179 d) is very similar, mostly larger, the uppermost submedian spot broadly flown together with the cellular spot which is larger here; beneath at the anal angle of the hindwing a larger orange spot. Venezuela, Colombia. *frater.*

D. virius *Mab.* is larger than *cypselus* (179 c, d), the spots on the forewing are of a deeper yellow, the cellular spot is larger, touching the quadrangular spot below it. The orange spot of the hindwing is somewhat indented at the proximal margin, the fringes are dark brown. Beneath the discal spots of the forewing form an angled band as far as the costal margin. Zamora (Ecuador). *viri.*

D. gelus *Mab.* (*vicina* *Mab.* i. l.) (179 d) is somewhat smaller than *cypselus* and *viri.* The spots on the forewing are the same, but somewhat larger and whiter, the two lower discal spots almost touch each other, the cellular spot is much smaller, placed near to the costal margin. The spot on the hindwing is likewise lighter yellow, larger, rounder. The hindwing beneath exhibits at the costal margin 2 additional yellow spots near the base and behind the discal spot, a third is situate at the anal angle. From Bolivia. *gelus.*

D. genes *Mab.* is larger than *cypselus* (179 c, d). Forewing jet-black with 3 subapical dots, the median one being minute, and 3 discal spots; that in the cell small, more remote from the others, light yellow; the spot in the submedian space is entirely absent. The spot on the hindwing is large, oval, orange, on the veins prolonged; fringes ferruginous. Beneath ferruginous, at the proximal margin of the forewing blackish. Hindwing reddish-brown, the discal spot blurred, only little lighter than the ground, bordered by 2 broken lines of a dull brown; proximal margin blackish; at the ends of the veins one black dot each. Zamora (Ecuador). *genes.*

D. ticias *Mab.* (179 d) is allied to the following species, but on the hindwing it resembles more *cypselus* by the oval spot. Discal spots in an oblique line, the two lower ones united, above them a streak in the cell, which may also be absent. Hindwing with an orange discal spot. Forewing beneath at the apex and at the costal margin red-brown, otherwise blackish; the discal spots are flown together into a very large one; hindwing reddish-brown, the spot not distinctly defined, traversed by 2 or 3 red-brown lines. Bolivia. *ticias.*

D. caenides *Hew.* (179 d) is very similar, the spot of the hindwing longer, the fringes more red-brown, beneath the discal spot of the hindwing is more sharply defined, not traversed by lines. Venezuela, Colombia. *caenides.*

D. connexa *sp. nov.* (179 e) is allied to *caenides*; on the forewing the triangular cell-spot forms a large quadrangle with the triangular spot below it, being diagonally parted by the median; at the distal upper angle another small triangular spot is connected with the apex, subapically there are 3 minute spots, all of them orange like the very large, oval, towards the base pointed spot on the hindwing; fringes at the anal angle orange. Beneath the apex of the forewing is reddish-grey, the discal spot very large, extended to the costal margin and proximal margin. Hindwing reddish brownish-grey, at the proximal margin blackish, in the disc strewn with yellow. Bogotá. *connexa.*

D. monospila *Mab.* Forewing blackish-brown, 3 united subapical dots, the 3 orange discal spots combined to one inclusive of a cellular streak, only separated by the veins, the distal one somewhat lighter. Hindwing black with a large ferruginous orange discal spot, equally broad and long, distally dentate. Fringes red-brown. Beneath like the preceding, the discal spot clear, the proximal margin blackish. Bolivia, Colombia. *monospila.*

D. cypria *Mab.* (179 d) is larger, forewing scarcely different; the spot of the hindwing very long, removed near to the costal margin. Fringes of hindwings whitish and thereby easily discernible. Hindwing beneath monotonously red-brown, discal spot little prominent, at the anal angle a small, yellow spot. Bolivia. *cypria.*

D. cupavia *Mab.* is very closely allied to the following *evages* (*scylla*), ground-colour above blacker, spots whiter, the cell-spot absent; on the hindwing the discal spot is smaller, quite round, the fringes dark ferruginous, at the proximal angle lighter; the hindwing beneath is more monotonous. Bolivia. *cupavia.*

D. evages *Hew.* (= *scylla* *Mab.*) (179 e) is above blackish-brown with 3 subapical dots, the middle one being the smallest; in the discal area 3 yellowish hyaline spots arranged in a line, above them in the cell another small one. The spot of the hindwing is distally somewhat dentate, as in *cupavia*, too, towards the proximal margin extended into a point. Fringes of hindwings yellowish-white. The forewing beneath is black, at the apex and costal margin reddish; the lower 2 discal spots are broadly flown together white; hindwing reddish-yellow, at the proximal margin light yellow, also at the costal and distal margins some dull, lighter patches. Bolivia. *evages.*

D. charybdis *sp. n.* (179 e) looks above almost like *scylla*, the spots are whiter, the fringes of the hindwings dark. Beneath all the red-brown and yellow tints are absent, the ground-colour is also on the forewings blackish-brown, the spots creamy-white, as above, but in addition there is one anal and one costal spot each near the base on the hindwing. Bolivia. *charybdis.*

- geon*. **D. geon** Mab. is allied to the two preceding, but well discernible by the hindwing beneath. Above chocolate with similar spots, but the cellular spot is triangular, united with the middle discal spot. Hindwing blackish-brown with a large, oval spot being produced somewhat proximally, fringes orange. Forewing beneath yellow, tinted blackish between the discal and apical spots as far as the proximal angle; hindwing yellow, towards the margin tinted reddish, the discal spot semicircularly surrounded by 6 ferruginous spots, that at the proximal margin being the largest. Ecuador (Loja).
- oxaites*. **D. oxaites** Hew. (= *syrisca* Mab.) (179 e, f) is somewhat smaller, the cell-spot is flown together with the discal spot below it to a large triangular spot, distally there is another one, the 3rd is absent; the black fringes are distally whitish. On the brown under surface of the forewing the spots are larger, the discal spots form a band; hindwing dark reddish-brown, beside the large white discal spot there is an oblong one at the base of the costal margin, a large one at the costal angle, at the base of the cell a small one which may also be absent, and along the distal margin 6 whitish spots of which that at the anal angle is the largest. Proximal margin bluish-grey. Bolivia.
- octomaculata*. **D. octomaculata** G. & S. (179 e) also belongs into this group. Above similar to *eryonas*, somewhat larger and with broader wings, with larger yellowish-white spots. Beneath the hindwing is without the costal-marginal and costal-angular spots, beside the discal spot there are only 2 at the anal angle. From Costa Rica.
- eryonas*. **D. eryonas** Hew. (= *dolabella* Plötz, *troetschi* Stgr., *heteropterus* Plötz, *fimbriola* Stgr. i. l.) (179 e) is very much like *oxaites*, but it only has 2 subapical dots, the 2 discal spots are better separated, on the hindwing the discal spot is more yellow, more oblong, extending farther to the proximal and costal margins. Beneath on the hindwing the whitish spots are much more extensive. From Panama through Colombia to Brazil.
- hesperioides*. **D. hesperioides** Fldr. (179 f) is a much larger species, on the body and at the bases of the wings orange or ochreous-yellow with similar spots on the forewings as in *oxaites*. The orange spot on the hindwings extends to the base and to the proximal margin; fringes broadly orange. Beneath reddish-yellow, behind the middle of the forewing black except the orange apex. Hindwing reddish-brown with torn yellow spots which are partly finely bordered with black. Colombia.
- polycrates*. **D. polycrates** Fldr. (179 f) is of the same size, above without any reddish-yellow, body and bases of wings somewhat haired olive-greenish. Spots of forewings white hyaline, the 2 middle ones not triangularly flown together, but only separated by the median. Hindwing with a small, round, orange discal spot. Beneath the hindwing is almost monotonously yellowish-brown with traces of a darker discal band. Colombia, Peru.
- superior*. **D. superior** sp. nov. (179 f) is still a little larger than *polycrates*. On the forewing the two discal spots are broadly flown together, the lower one triangular, all slightly yellowish. On the hindwing there is beside the bipartite orange postdiscal spot another basal one. Beneath the forewing shows a broad, yellow discal band, the hindwing is dark red-brown with 3 slightly darker transverse bands which are on both sides bordered by undulate, fine, dark lines, one being situate basally, one in the middle with a long dentiform projection below the costal margin, the third being antemarginal, the margin itself being narrowly darkened. Colombia: Monte Tolima; (FASSEL).
- caicus*. **D. caicus** Hew. (179 f) looks above almost like a large *eryonas*, but above the middle of the proximal margin of the forewing it has one more white discal spot; the spot of the hindwing is white, large, rounded. Beneath the hindwing is yellow, veined brown with the large, quadripartite discal spot and one more white spot bordered with brown each at the costal angle and anal angle. Venezuela.
- inca*. **D. inca** sp. nov. (179 g) is very closely allied to *caicus* and above scarcely different, but the white spot of the hindwing is not so round, but the cellular part more oblong; fringes of hindwings distinctly speckled light and dark. Beneath all the yellow and brown tints are absent. The apex of the forewing is lighter, grey, the hindwing white, scantily dusted with grey, otherwise marked as *caicus* except the longer light cell-spot. On the whole larger. From South Peru (Madre de Dios), taken by FASSEL.
- ligilla*. **D. ligilla** Plötz (179 g) is similar; above the 4 discal spots are fused into a single one, the spot of the hindwing is decidedly yellow, also the fringes which are speckled a little darker. Beneath on the hindwing the brown colour is more predominant; at the base of the cell there is another long, light yellowish wedge-shaped spot. Patria not stated.
- dimidiata*. **D. dimidiata** Fldr. (179 g). Forewing spotted as in *oxaites*, hindwing with a large, white discal spot extending to the costal margin, the proximal margin very much haired bluish-grey. Beneath unmistakable, owing to the hindwing being white in the basal half and distally deep red-brown with blackish spots. Venezuela, Colombia, Bolivia. In f. **xantholeuca** Plötz (179 g) from Venezuela the basal part of the hindwing beneath is purely yellow.
- jelskyi*. **D. jelskyi** Ersch. (179 h) is very different. Above almost as *oxaites* (179 e, f). Beneath the hindwing is yellowish with dark brown veins except the transverse vein, so that in the middle a long stripe of the ground-colour extends from the base to the margin. From Peru and Bolivia.
- lalage*. **D. lalage** G. & S. (179 h). Above blackish-brown with a large discal spot and a subapical spot of orange colour, the spot of the hindwing large, orange, like the fringes. Beneath almost entirely light yellow, only the forewing exhibits a blackish antemarginal band being forked towards the costal margin. From Mexico.

D. lethaea Schs. is above coloured and marked almost as *lalage* (179 h). Beneath the wings are deeper yellow, the cell of the forewing is black almost to the end, towards the base also below the cell; behind it there is a broad black band not reaching the costal margin, being distally bent above the upper radial vein and reaching the proximal angle beneath. The base of the proximal margin of the hindwing is scaled black. Costa Rica (Poas). *lethaea.*

D. lysis Schs. resembles somewhat the following *faula* (179 h); the forewing exhibits in the cell a yellow triangular spot, below it behind the middle between the median veins a small spot and above it farther distally yet a dot; distally below the costal margin a short oblique streak. The hindwing shows the large discal spot of *faula*. Beneath the forewing is blackish-brown with a yellowish-brown costal margin, the distal margin narrowly, the apex somewhat more broadly yellow, the yellow discal spot enlarged. Hindwing yellowish-white, veined brown except the transverse vein and base of the middle radial vein remaining coloured like the ground. Fringes brown. Costa Rica (Turrialba). *lysis.*

D. faula G. & S. (179 h) is very much like *lalage*, the spots somewhat lighter yellow, the discal spot somewhat differently shaped; the hindwing shows a long, narrow discal stripe which is parted at the lower margin by the median. Beneath likewise light yellow, the blackish marking somewhat more extended the hindwing dusted with brownish-grey except the cell. From Mexico. *faula.*

D. arpia Schs. (179 h) likewise belongs hereto, but the subapical spots are entirely absent and the discal spot extends from the subcostal vein to the submedian fold. Beneath almost as *lalage*, but the base of the forewing is black and above the cell connected with the distal-marginal band not being forked. Hindwing quite light yellow. Described from Rio de Janeiro, but it also occurs in Bolivia and is thus certainly widely distributed. *arpia.*

D. pruna Plötz (179 h) from S. Domingo is perhaps only an insular form of the preceding with smaller spots above. Beneath the colour is more yellowish-grey; on the forewing only the apex is yellowish, the distal margin is from the middle downwards dark brown like the proximal two thirds of the costal margin and the whole basal half. *pruna.*

D. seirocastnia sp. n. (179 i) is above deep blackish-brown with an orange, bipartite discal spot and 3 subapical dots of the forewing. Hindwing in the disc deep orange, broadly bordered with blackish-brown with orange fringes. Beneath the forewing the costal margin, apex and narrowly the distal margin are strewn with red-brown. The hindwing is densely dusted with red-brown, but in the disc the yellow ground-colour is scarcely visible; proximal margin black, strewn with yellow. From Colombia (Monte Tolima). *seirocastnia.*

D. privata sp. nov. (179 i) resembles the preceding on the forewing above, but the discal spots are smaller; the hindwing is entirely blackish-brown without an orange discal area. Fringes red-brown, only at the anal angle of the hindwing somewhat more orange, parted by a dark discal line. Beneath the hindwing is quite red-brown, but very scantily strewn with yellow. Bolivia (Cuesta of Cillutincara). Type in the Coll. FASSL. *privata.*

D. agathocles Fldr. (9 i). Here begins a small group of species with several yellow spots of the hindwing. *agathocles* is above blackish, the small spots of the forewing are yellowish-white, insignificant. The hindwing exhibits a large basal spot and behind it 3 distal-marginal spots, the two upper ones of which are situate close together. Beneath the forewing is reddish-yellow in the basal and inner-marginal half, apically blackish. The hindwing is red-grey with 2 slightly conspicuous yellowish transverse bands. Colombia. *agathocles.*

D. pulchra G. & S. (179 i) is similar, somewhat smaller; on the more chocolate ground the forewing exhibits one more light yellow spot in the submedian space, which is situate farther towards the base. The hindwing only shows 3 deep orange spots, 1 towards the base, 2 distally; the fringes of the hindwing are also deep orange. From Costa Rica. *pulchra.*

D. saleca Mab. (179 i) likewise very much like *agathocles*. The spots of the forewing are more reddish-yellow, the cellular spot very much nearer to the spot below it. The fringes of the hindwing are dark red-brown. Beneath the whole basal half, the costa and apex are blackish red-brown, only the discal macular band is reddish-yellow. The hindwing is likewise red-brown, the bands not very conspicuous. Colombia, Peru. — From the Cuesta of Cillutina (FASSL) a form is before us: **albescens** sp. nov. (179 k) with larger, entirely white spots. *saleca.* *albescens.*

D. bubobon Dyar. Above bronze-black, spotted yellow: 1 obliquely quadrangular spot in the cell, 2 faded ones below it, 2 more between and above the median veins, the lower one larger, below it another small, dark yellow spot; hindwing with yellow discal spot and 4 behind it, fringes speckled light. Beneath the spots are larger, more numerous, particularly on the hindwing, where also 3 round spots are situate at the costal margin. Expanse of wings: 36 n. Mexico (Guerrero). *bubobon.*

D. grovius Mab. is larger than *bubobon*, the forewing with 3 subapical dots, a cellular spot and behind it and below it with 4, not 3 more spots. The spot of the hindwing is prolonged, of a brighter yellow than on the forewing, from the costal margin a pointed tooth of the ground-colour penetrates into it; at the distal margin there is only between the median veins a yellow spot. Fringes of hindwings orange. Beneath as *saleca*, but on the red-brown hindwing there are 3 distinct light yellow bands, a broad basal band, another one being connected with it extends to the anal angle, the third being extinct and situate near the fringes; on the ends of the veins there are black dots. Ecuador (Loja). *grovius.*

D. epiphaneus Fldr. (179 i) is still larger, at the bases of the wings dusted with ferruginous-brown, with large band-shaped, reddish-brown spots as far as the proximal margin. The hindwing exhibits a basal *epiphaneus.*

spot and a large quadrangular one between the radial veins, sometimes another smaller one below it. Beneath the hindwing is red-brown with deeper red-brown, torn macular bands. Venezuela.

gaujoni. **D. gaujoni** Mab. is allied to *epiphaneus*. Above black with 3 confluent subapical dots and 3 separate discal spots, the lowest punctiform, the third touching the cellular spot. Hindwing with 3 large, reddish-yellow spots, one of which is at the base of the cell. Fringes at the ends red-brown. Beneath the hindwing is red-brown with the spots as above, bordered by 4 black transverse lines, the basal spot being double owing to another one being situate above it. Ecuador (Zamora).

ochrolimbata. **D. ochrolimbata** sp. nov. (179 k). Above blackish-brown with a coppery reflection and ochreous-brown fringes. In the cell-end and below it there are 2 insignificant, small, ochreous-yellow spots and subapically 3 minute dots. Beneath the apex of the forewing, and the hindwing are chestnut, the spots of the forewing are expanded and lighter towards the proximal margin. According to 1 ♂ from Peru (Pozuzo) from the Coll. SEITZ.

quadristriga. **D. quadristriga** Mab. (179 k) initiates a group of smaller species being above unmarked blackish-brown. The fringes are somewhat lighter, the forewing is scantily strewn with yellowish scales. Beneath the forewing is jet-black in the basal two thirds, at the apex and the costal margin red-brown; at the margin there is a triangular, reddish-white spot, tripartite by the veins, beginning near the proximal angle. Hindwing red-brown with 4 rows of small black strigiform spots, forming dissimilar transverse lines costal margin and submedian space blackish. Expanse of wings: 28 mm. Described from Merida (Venezuela).

boliviensis. **D. boliviensis** Mab. is very much like *quadristriga*: above brown with a lighter reflection and a yellowish middle of the distal margin and black veins; fringes dark grey. Forewing beneath blackish, at the costa and apex greyish-white, in the submedian space a large, white triangular spot with 2 small ones above it; proximal margin ashy-grey. Hindwing dark grey, at the costal margin almost black and with 3 small brown bands in the middle of the wing, the 2 distal ones close together, near the costal angle rectangularly broken, at the costal margin united; the 3rd at the cell-end is more blackish. Bolivia.

merula. **D. merula** Mab. (179 k) is above monotonously brownish-black, between the veins with a somewhat reddish reflex and with dirty grey fringes. Beneath black, the proximal margin of the forewing, the distal half of the submedian space and a spot above it are purely white; the blackish hindwing is powdered with yellow or yellowish-grey atoms, at the proximal margin more densely so, and traversed by 3 blackish, undulate lines, 2 nearing each other at the margin, a broader, somewhat blurred one in the middle. Bolivia (Chaco). It is perhaps synonymous with *eburones* (p. 925).

morva. **D. morva** Mab. is brown with a light ferruginous reflection, veins and marginal line black, fringes red-brown. Beneath the forewing is yellowish-grey, dusted with a light grey, the middle of the margin blackish, the proximal margin in a triangular shape dirty white. Hindwing dark yellowish-grey, strewn with yellow with 3 fine blackish transverse lines which are somewhat blurred. Bolivia.

riza. **D. riza** Mab. is ferruginous-brown with a red reflection; the forewing exhibits 2 subapical dots, the upper quadrangular one being larger, a third reddish white spot is situate in the disc between the lower radial veins. The margin is narrowly blackish. Hindwing similar, between the upper radial veins and below the costal margin with 2 small lighter red-brown spots, just like the inner-marginal fold covered with long yellow hair. Forewing beneath light ferruginous, the inner-marginal part yellow, below the discal spot a yellow dot; on the ends of the veins there are black dots. Hindwing in the disc light violet ferruginous-brown at the base, between the veins with two brownish-black strigiform lines. Expanse of wings: 22 mm. Colombia.

granites. **D. granites** Mab. is allied to *riza*. Forewing with 3 subapical dots and 2 white spots in an oblique line between the median veins, the lower large, quadrangular, almost fused with a similar cell-spot; hindwing black with red-brown fringes. Forewing beneath black, at the costa and ex red-brown, the spots form a band being below light yellow, above reddish-yellow. Hindwing light red-brown with 2 small undulate stripes beginning at the blackish proximal margin and disappearing in the middle. Ecuador (Loja).

polydesma. **D. polydesma** Mab. Above brown with 3 light yellow subapical dots and a spot in the middle of the cell and 2 more behind it and below it. Hindwing with a dot in the middle of the cell and 4 greyish-yellow ones behind it in the shape of a small discal band. Forewing beneath very light reddish-yellow, distally blackish, at the apex reddish-brown. Hindwing light reddish-brown with blackish lines, composed of bent streaks, bordering on an irregular oval, beneath bordered by a dentate line; a cell-end break. Expanse of wings: 28 mm. Venezuela (Merida).

ibhara. **D. ibhara** Btlr. (= *crithote* Hew., *plancus* Hpffr.) (179 k) is above blackish-brown with a slight olive tint and somewhat lighter spots on the forewing: one in the cell, one behind it and below it, by two far distally removed spots connected with the 2 subapical ones to a curved line; in the submedian space, separated by the fold, 2 more oblong nebulous spots. Beneath light brownish-grey, the disc blackish, the spots whiter, near the proximal margin united into a large triangular spot. Hindwing strewn with yellowish-grey scales, traversed by 4 fine, undulate transverse lines. Ecuador, Peru, Bolivia, and in Brazil (Pará).

gyrans. **D. gyrans** Plötz (= *anomala* Mab.) (180 a). Above similar, but the spots only punctiform, and instead of the 2 submedian spots there is only 1 dot removed far proximally. The hindwings are unspotted or exhibit

2 or 3 insignificant discal dots. Beneath densely strewn with grey, proximal margin of forewing lighter, hindwing with dull, darker, small postmedian dots. Mexico.

D. microsticta *G. & S.* (180 a) is smaller, the number of the dots on the forewing is variable (4 to 6), hindwing without spots; beneath strewn lighter, otherwise as above, proximal margin of forewing broad whitish. The ♀ exhibits also above on the hindwing 4 or 5 dots. Mexico. *microsticta.*

D. ceracates *Hew.* (180 a) is larger, stronger than *gyrans*, the white spots larger; the hindwing exhibits above a basal spot and 3 postdiscal ones, one of which is generally isolated at the proximal margin. Beneath loam-coloured, forewing in the inner-marginal area blackish, hindwing very much strewn with greyish-yellow, the spots rather inconspicuous. Mexico. *ceracates.*

D. cyclosticta *Dyar* (180 a) is somewhat larger than *ceracates*, above the forewings are marked the same, but the white spots are much smaller, punctiform; hindwing entirely unmarked, fringes not whitish as there, but reddish-brown. Beneath the forewing is much lighter, yellowish-brown, at the proximal margin marked still lighter than above; hindwings darker than forewings, of a reddish brown, strewn somewhat lighter. Mexico (City) in August. *cyclosticta.*

D. aea *Dyar* (180 a) is much smaller, black with small white punctiform spots as in the preceding, subapically only 2 and below the cell-dot a somewhat longish spot, hindwing with 2 or 3 minute discal dots. Beneath with a slight brass lustre, the white spots more distinct, on the hindwing increased, behind the cell-spot there are 2 rows of dots, that next to the anal angle being removed towards the base. Mexico (Guerrero, Oaxaca). *aea.*

D. penaea *Dyar* (180 a) is extremely similar, above with a bronze tint, the small spots light yellowish; on the hindwing there are behind a cell-spot 3 spots in a bent row. Beneath densely strewn with yellow, the spots more numerous and whiter, on the hindwing behind the cell-spot at first a row of 5 spots, nearer to the distal margin another row of 7 spots, the latter being small and irregular. Described from Mexico (Sierra de Guerrero). *penaea.*

D. polingii *Barnes* (180 a) has been placed into the genus *Hesperia*, but according to its characters it undoubtedly belongs hereto and it also fits very well into the affinities of the preceding species. On the forewing marked exactly as *ceracates*, often besides with a small submedian spot towards the anal angle. Hindwing with a group of 2 or 3 insignificant, a little lighter, small postcellular spots. Beneath olive-brownish, on the hindwing with a reddish tint; inner-marginal area of the forewing broad whitish. Hindwing well distinguished by 3 or 4 larger, rounded, yellowish-white postdiscal spots. Arizona to Mexico. *polingii.*

D. diraspes *Hew.* Above dark brown, on both wings with a yellow discal spot. Beneath the forewings are dark brown, base, a discal band, apex and distal margin light yellow. Hindwing light yellow. Expanse of wings: 1.1 inch. From Rio de Janeiro. This species may be synonymous with *arpia* (179 h)? *diraspes.*

D. eburones *Hew.* is above uni-coloured unmarked dark blackish-brown. Beneath dark brown, strewn with whitish, forewing with a large, tripartite, white inner-angular spot and towards the apex above it 3 indistinct lighter spots. Expanse of wings: 1.05 inch. Bolivia. *eburones.*

D. hilina *Btlr.* has remained unknown to me, it is said to be allied to *cypselus* (179 c, d) and *dimidiata* (179 g). Above olive-brown, forewing with 7 yellow hyaline spots as in *cypselus*, hindwing with a large, yellow discal spot with a silky lustre, distal margin black; fringes orange, body greenish. Beneath brown, towards the margin ochreous, the spots larger than above; hindwing ochreous-yellow, the large yellow spot surrounded by 7 brown spots. Expanse of wings: 1.4 inch. From Venezuela. *hilina.*

D. brunnea *Seddr.* is above blackish-brown, only the forewing with 2 minute dots. Beneath the same, the proximal margin of the forewing lighter; behind the cell two more dots, one between the median veins and one near the apex. From Guatemala. *brunnea.*

68. Genus: **Eumesia** *Fldr.*

The short antennae do not reach to the middle of the costal margin; the porrect palpi have a slender, stunted terminal joint. Distal margin of forewing much longer than the proximal margin; the upper median vein of the forewing with a bent course rises far before the cell-end. The strongly spined posterior tibiae exhibit 2 pair of spurs. Beside the typical species of *FELDER* another one has been described as *Eumesia*, but it is doubtful whether it belongs hereto.

E. semiargentea *Fldr.* (191 h) is at once recognizable by the contrast of the uni-coloured dark brown forewing with the silvery lustrous greyish-white hindwing. On the under surface the forewing is pale ochreous, the hindwing dirty white with a darker costal margin and proximal margin. Colombia. *semiargentea.*

E. potomoni *Weeks*, described according to a ♀, is above bronze-brown, at the base and margins darker, with a black dot at the cell-end and 2 subapical hyaline dots, from which a bent, dark line proceeds extending to the submedian space; hindwing the same with 2 dark discal streaks. Beneath lighter brown, marked the same as above. Expanse of wings: 1¾ inch. Venezuela (Suapure). *potomoni.*

69. Genus: **Argopteron** *Wts.*

Discernible from the preceding by the posterior tibiae being only singly spurred, the abdomen being longer. The 2nd and 3rd palpal joints intensely scaled, porrect; in the veins no essential difference. Several species from South America.

aureipennis. **A. aureipennis** *Bleth.* (= *flavimargo* *Plötz*, *tripunctatus* *Mab.*) (191 h) is very conspicuous by the purely golden under surface, only in the ♀ the disc of the forewing is dark brown, with the 2 golden discal spots, the 3rd disappearing in the golden apex. The upper surface is dark brown with 3 large yellow spots on the forewing and yellow fringes of the hindwing. Chile.

dividuum. **A. dividuum** (180 b) is above blackish-brown with a hyaline discal band, parted by the median and its lower branch, a small punctiform spot towards the margin and 3 small subapical spots; hindwing with a dark yellow postmedian band composed of one large quadrangular spot and 3 narrow small spots below it; the yellow fringes are speckled somewhat darker. Beneath the forewing is as above, the discal band vanishing in the whitish proximal margin, hindwing brown with numerous yellow spots. Mexico.

xicca. **A. xicca** *Dyar* would perhaps be better placed to *Dalla* into the *quadristriga*-group. Above uni-coloured black, inner-marginal part of hindwing with long greenish hair. Beneath dull black, base of costal margin and apex greyish-brown; hindwing greyish-brown with a black stripe on the submedian fold, expanded at the proximal angle to a spot. Peru, Vilcabamba, at an altitude of 10 000 ft., in August.

puelmae. **A. puelmae** *Calvert* (191 g) is a magnificent species allied to *aureipennis* from which it differs by the hindwing being quite golden also above. The blackish-brown forewing exhibits a large tripartite discal spot and a subapical band. Beneath golden, only the ♀ has a dark cell-end spot and a slightly smoked margin of the forewing. In January in North Chile.

metius. **A. metius** *Mab.* It is doubtful whether this species and the next one having been described as *Cyclopides* belong hereto. Above blackish-brown with yellowish hyaline spots: 3 small subapical ones, 3 small ones at the cell-end, an oblique row of 3 quadrangular ones between the lower median and middle radial vein. Fringes yellowish-white. Beneath the costal margin of the forewing is reddish-brown, the apex lilac, the hindwing reddish-lilac with a violettish-brown costal margin, in it an oval yellowish spot, another one below it extending from the upper radial vein to the proximal margin. Fringes speckled dark. Expanse of wings: 21 mm. Porto Cabello.

celeus. **A. celeus** *Mab.* is described as yellowish-brown, at the base of the forewing striped yellow with 3 yellow sagittiform spots in the cell and 7 reddish-yellow postdiscal spots, the 3 upper ones as apical streaks, the 4 others below them as far as the proximal margin. Hindwing margined with 3 longish, reddish-yellow spots, the middle spot being double. Fringes yellowish-white. Beneath light brown, tinted yellow, with yellow veins and the spots as above. Hindwing with light yellow veins, also the folds with yellow strigiform spots between the upper median vein and the costal margin. Expanse of wings: 25 mm. Villa Bella.

70. Genus: **Pamphila** *F.*

This species being chiefly distributed in Europe and Asia sends a European representative to North America. It has been dealt with in the palearctic part (Vol. I, p. 344). Posterior tibiae only with end-spurs, the short antennae do not reach to the middle of the costal margin.

mandan. **P. palaemon** *Pall.* (= *paniscus* *F.*, *brontes* *Schiff.*, *mandan* *Edw.*, *mesapano* *Scddr.*, *skada* *Edw.*) (Vol. I, t. 87 c) is figured in the palearctic part and occurs in the whole northern United States in a very much orange-spotted form which we may call: f. **mandan** (180 b).

floridae. **P. floridae** *Mab.* Above olive-grey with small yellowish-white spots on the forewing, 3 subapical ones, 2 in the cell and 2 behind it in an oblique line; fringes ashy-grey. The ♀ has only one cellular spot; beneath more purely ashy-grey, disk and proximal margin of forewing blackish. Proximal margin of hindwing lead-coloured grey, the spots less distinct. Florida.

dardaris. **P. dardaris** *G. & S.* (180 b) is above blackish-brown, in the middle of the wing with a large, bipartite, white spot, a dot behind it and 2 subapical dots. Hindwing with 2 small spots. Beneath browner with much more numerous spots being somewhat yellowish on the hindwing. Inner-marginal part of forewing broadly white. Mexico.

daridaeus. **P. daridaeus** *G. & S.* has more spots on the forewing. The hindwing is beneath greyer, the white spots less prominent, in the disc strewn with single, small, black spots. Described from Brazil.

calaon. **P. calaon** *Hew.* may belong hereto. Upper surface reddish-brown, forewing with yellow hyaline spots; one in the cell, 2 between the median veins, a double spot near the proximal margin and 3 small subapical spots. Hindwing with a spot near the proximal margin and 3 small subapical spots. Hindwing with a spot near the costal margin, a longish cell-spot and a short macular band behind it; fringes reddish. Beneath similar, but the base and the apex of the forewing are reddish-yellow; hindwing red-brown, the spots whitish, bordered with black; at the costal margin there are 2 spots and near the distal margin a light yellow band. Expanse of wings: $1\frac{1}{4}$ inch. From Ecuador.

P. quinquemacula *Skinner* is above blackish-brown with 3 white subapical dots and 2 postdiscal spots. Beneath as above, hindwing with 2 large, white spots near the costal margin and 8 small white postdiscal dots. Expanse of wings: 21 mm. New Mexico. *quinque-macula.*

Group B.

The antennae of this group are of a very different shape, but never flared; the club is either not curved or only slightly. Palpal terminal joint either long and slender, bent across the vertex, or very short. The cell of the forewing is always shorter than $\frac{2}{3}$ of the costal margin; the middle radial rises nearer at the lower than at the upper, and at its base it is mostly bent somewhat downward. Hindwing at the anal angle often somewhat prolonged, but never extended like a tooth or even into a tail. The ♂ never shows a costal fold, but very often a scent-scale stripe or several mostly below the median. The doubly spurred posterior tibiae do not bear a hair-tuft. Characteristic is the way the wings are kept: while at rest and in the sun the forewings are upwardly tucked over, the hindwings expanded horizontally, the latter also upwardly tucked over only when entirely at rest. This group comprises the lepidoptera being by far the most difficult to determine, often exhibiting a most remarkable homogeneity in their exterior.

71. Genus: **Apaustus** *Hbn.*

Antennae very short with a moderately strong, straight club, palpal terminal joint long and slender. Distinguished by the very long, slender abdomen projecting far beyond the hindwing. No scent-scales.

A. menes *Cr.* (180 b). Blackish-brown with 3 yellowish subapical dots and a narrow yellow base of the costal margin. Beneath the same, though lighter, at the apex of the forewing veined yellow, also the hindwing. Abdomen beneath whitish. Panama to Colombia. Guiana, Amazon, Brazil. *menes.*

72. Genus: **Oarisma** *Seddr.*

The antennae have only the length of $\frac{1}{3}$ of the costal margin, but the obtuse club itself is very long. The 2nd palpal joint is long-haired, the 3rd long and slender. Forewing at the apex a little stunted; abdomen also here very long.

O. powesheik *Pack.* (180 b) is lustrous dark yellowish-brown, fringes and costal margin of hindwing dark brown. Forewing beneath reddish-yellow, at the proximal margin blackish-brown, hindwing greyish-yellow, proximal margin broadly yellow, fringes at the anal angle white. North America to Mexico. — Specimens from these southern habitats exhibit the hindwing in the distal-marginal half more or less reddish-yellow: f. **isidorus** *Plötz* (180 b). *powesheik.*
isidorus.

O. garita *Reak.* (= *hylax* *Edw.*) (180 c) is smaller, with shorter wings of a darker colour. Colorado, Mexico. *garita.*

O. edwardsii *Barnes.* The description of this species was unfortunately not accessible to us. *edwardsii.*

73. Genus: **Adopaeoides** *G. u. S.*

Distinguished from the preceding genera by the shorter antennal club.

A. simplex *G. & S.* (= *prittwitzi* *Plötz*) (180 c) is above reddish-yellow with a blackish margin, a blackish margin of the hindwing and a darkened base and proximal margin. Beneath plainly yellow with a black proximal margin of the forewing. Mexico. *simplex.*

A. bistrata *G. & S.* (180 c) resembles *O. powesheik*, but beneath on the hindwing it shows 2 white longitudinal stripes, the fringes are not white. Above the forewing exhibits a dark cell-end streak. Described from Mexico. *bistrata.*

A. boeta *Hew.* (= *bilineata* *Dogn.*). We were unfortunately not able to find the description of this species. *boeta.*

74. Genus: **Ancyloxypha** *Fldr.*

Antennae as in *Oarisma*. Palpi long, the 2nd joint loosely haired, the 3rd slender, somewhat upturned. The slender abdomen projects somewhat beyond the anal angle.

A. numitor *F.* (= *puer* *Hbn.*, *marginatus* *Harr.*) (180 c). The ♂ is above on the forewings dark brown, on the hindwings being bordered with black it is reddish-yellow; in the ♀ also the forewing is reddish-yellow with a broad black distal margin. Beneath yellow with a black disc and proximal margin. Atlantic States. *numitor.*

A. longleyi *French* is more strongly built than *numitor*, the costal margin of the forewing is straighter, the apex more pointed, the terminal joint of the palp somewhat longer. Above monotonously dark brown with a slight blue reflection; hindwing yellow, margined with brown. Beneath almost as *numitor*, but a little darker, hindwings uni-coloured yellow. From Chicago. *longleyi.*

- arene.* **A. arene** *Edw.* (= *tucumanus* *Plötz*, *leporina* *Plötz*) (180 c) is above plainly reddish-yellow with a blackish distal margin at apex of the forewing as well as costal margin of the hindwing, and a thin black cell-end streak. Beneath plainly yellow, proximal margin of forewing black. Arizona, Mexico to Venezuela and Peru. — f. **euphrasia** *Plötz* (180 d) is marked by the ♀ forewing being suffused with dark brown; from Mexico.
- nanus.* **A. nanus** *Plötz* (180 d) is a smaller species from Cuba, closely allied to the preceding. Above the forewing is dusted with brown except the cell remaining yellow; beneath with somewhat darker veins.
- xanthina.* **A. xanthina** *Mab.* Forewing black with a yellow apical spot and 2 similar longitudinal bands, one along the costal margin to the cell-end, the other widening distally and divided into 4 spots. Hindwing black with a yellow, longish, triangular spot occupying the whole margin, fringes reddish-yellow. Forewing beneath yellow with a black band disappearing at the proximal margin. Hindwing yellow, between the veins shaded brownish, whereby they are more prominent. Expanse of wings: 20 mm. Valera.
- melanoneura.* **A. melanoneura** *Fldr.* (180 d) is easily recognizable by the black veins above. Beneath the hindwing is brownish with 2 white longitudinal stripes. Colombia.

75. Genus: **Copaeodes** *Speyer*.

- Antennae short as in the preceding with a straight, strong club with stunted apex. Palpi as in *Adopaea* (Vol. I, p. 346). The distal margin of the forewing is a little excised in the lower half. The abdomen projects beyond the anal angle. The ♂ exhibits a fine scent-scale stripe extending from the base of the median along the median to the upper median vein, below which it extends to its first third.
- singularis.* **C. singularis** *H.-Schäff.* (= *aurantiaca* *Hew.*, *waco* *Edw.*, *minima* *Edw.*, *candida* *Wright*, *macra* *Plötz*) (180 d) is above and beneath uni-coloured light reddish-yellow, the scent-stripe fine black. Beneath the hindwings are scarcely noticeably veined darker. Texas, Arizona, California and from Mexico to Panama, also in Cuba.
- wrightii.* **C. wrightii** *Edw.* (180 d) is extremely similar, somewhat larger, more robust, with broader wings, at once discernible by the smoked fringes; the scent-scale stripe is a little steeper. California.
- myrtis.* **C. myrtis** *Edw.* (180 d) in contrast with it is smaller, with narrower wings, towards the distal margins smoky, more broadly at the apex. Costal margin of hindwing broad dark, distal margin narrowly bordered with dark. Beneath the base of the forewing is black. Arizona.
- eunus.* **C. eunus** *Edw.* (180 e) is as large as *wrightii*, with a narrow black marginal line; the veins towards the latter somewhat darkened, the margin very feebly and narrowly smoked. On the hindwing beneath the ground between the broadly lighter veins is strewn with a greenish grey. California.

76. Genus: **Chaerephon** *G. u. S.*

- Antennae as long as half the costal margin, club short, at the apex pointed somewhat like a hook. The terminal joint of the palp is shorter than in the preceding and half erect. Apex of forewing pointed, in the ♀ more obtuse. Middle and posterior tibiae spiny, the latter with double spurs. In the ♂ of *citrus* a narrow scent scale stripe which is absent in *rhesus* extends from the rise of the upper median vein obliquely to the inner-marginal vein.
- citrus.* **Ch. citrus** *Mab.* (180 e). Dull greyish-brown, reddish-yellow, with greenish scales at an oblique exposure to light, particularly on the costal margin and in the basal half of the forewing, with some blurred, reddish-yellow, subapical and postdiscal small spots, also on the hindwing. Fringes greyish-white. Beneath greyish-yellow, strewn with blackish, except a postdiscal band of spots, and with small, black internodal spots. Scent-stripe black. The ♀ is duller in its colour with more distinct yellow spots above. Mexico, Honduras, Guatemala.
- rhesus.* **Ch. rhesus** *Edw.* (= *subreticulata* *Plötz*, *axius* *Plötz*) (180 e) is much larger, blackish-brown, of a more greenish tint with larger and more distinct spots. Also beneath more blackish-brown with an olive tint and white spots; the forewing exhibits a large, white inner-marginal spot, the hindwing one more basal band of spots being broken in an acute angle. Colorado, Arizona to Mexico.

77. Genus: **Hylephila** *Bill.*

- Scarcely distinguished from the preceding genus; palpi and antennae the same. On the somewhat longer forewing the lower median vein rises much nearer at the base, in the ♀ somewhat farther than at the cell-end. Distal margin of hindwing somewhat concave before the anal angle. The scent-scale stripe extends as in *Chaerephon* and is distally bordered by a series of erect scales.
- phylaeus.* **H. phylaeus** *Drury* (= *augias* *Hbn.*, *hala* *Blkr.*, *ancora* *Plötz*, *bucephalus* *Steph.*) (180 e). The ♂ is above reddish-yellow, with black wedge-shaped streaks before the distal margin, a long black spot behind the cell

of the forewing, a broad black stigma, and dark costal margin of the hindwing. The ♂ is dark brown with a band of yellowish-red spots. The under surface is light yellow, in the ♀ dark olive-grey on the hindwing. Very widely distributed and mostly common in the eastern and southern States of North America, from Mexico to Argentina and in all the West Indian Islands. — The light green pupa with darker green dorsal and lateral stripes lives on herbs and changes into a light green pupa.

H. andina *Stgr.* might be a dark local form of *phylaeus*. It differs by much broader blackish-brown distal margins of all the wings, not being dentate on the hindwings. The costal-marginal part of the hindwing is also much broader dark, also the veins and the inner-marginal part, so that almost two thirds of the surface of the wings are dark. The under surface is much more intensely spotted dark, especially on the hindwing, which mostly are of an ochreous-brown ground-colour. From C'ocapata (Bolivia).

H. peruana *sp. nov.* (180 f) is somewhat smaller than *phylaeus* and is very closely allied to *fasciolata*, on the ♂ forewing scarcely different, the black longitudinal spot at most behind the upper cell-end being somewhat larger and thicker; the hindwing exhibits below the cell yet 2 small black longitudinal spots. The ♀ is much lighter yellow. The under surface is quite different: dull ochreous-yellowish, in the ♀ almost without any reddish tint, the markings from above repeated in distinct, small, jet-black, wedge-shaped spots which are smaller than above and all well separated by light veins. From Cuzco (Peru).

H. fassli *sp. nov.* (180 f). There only exists one ♀ for which reason its position is not certain. Thrice as large as *peruana*, above light yellow as the ♀ of *peruana* with an ochreous-reddish tint, marked as there, but the black markings particularly of the distal margins are much broader; especially on the hindwing proximally not dentately, but straightly defined; on the middle radial vein the yellow colour projects pointedly towards the margin, whilst from the cell it is followed in an acute angle by a black discal angular spot; fringes ochreous, towards the apex feebly speckled. The under surface is most peculiarly and differently marked. On the forewing similar as above, but duller, the small subapical spots whitish, the anal angle lighter. Hindwing likewise as above, but much lighter, the margins strewn with a violettish grey, the subcostal within the cell distinctly whitish-yellow, below it whitish hairing; behind the inner-marginal fold there is a blackish longitudinal spot, the anal half of the wing more sand-coloured yellow. 1 ♀ from Cuzco (Peru), taken by FASSL.

H. isonira *Dyar* (180 f) is very closely allied to *phylaeus*; in the ♂ the black margins are broader, almost forming a proximally dentate band. The ♀ is only slightly darker than the ♂, the markings not so much flown together. Beneath light yellowish, hindwings tinted grey with a lighter discal band, bordered by a dark red, sharply broken, the lower segment straighter than in *phylaeus*, not spotted black. From Peru, rising to altitudes of 14 000 ft., in July and October.

H. fasciolata *Blch.* (= *emma* *Plötz*) (180 f) is somewhat smaller and stouter than *phylaeus*, of a deeper reddish-yellow, above somewhat more intensely marked black; also the ♀ is marked and coloured almost like the ♂, instead of the scent-stripe there are 3 small black spots. The principal difference consists in the very much black-spotted under surface. From Chile.

H. fulva *Blch.* (= *grynea* *Plötz*, *hujana* *Plötz*, *antaretica* *Mab.*) (180 f) is larger, especially the ♀ is much more intensely marked black; beneath the ♀ is much strewn with brownish-grey, with a white postdiscal macular band and cellular spot, the ♂ is light yellow with small black punctiform spots and a black proximal margin of the forewing. Chile.

78. Genus: **Erynnis** *Schrk.*

The antennae are somewhat longer than in *Hylephila*, but still shorter than half the costal margin; the club is longer, the hook-shaped apex better developed. The scent-scale stripe of the ♂ is broader and extends to the rise of the lower median vein. Otherwise not different from the preceding genus.

E. comma *L.* (= *virgula* *Retzius*) has been dealt with in the palearctic part (p. 348, t. 88 d) and occurs in a number of forms in America. — f. **manitoba** *Scddr.* (180 f, g) is a slender form above lighter yellowish-brown, with slightly darkened margins above. Beneath on the hindwing the whitish marginal band is quite coherent and sharply angled, the ground-colour dark brown or with a greenish tint. To the north as far as Canada, to the south as far as Colorado and North California. — f. **viridis** *Edw.* (180 g) is on the hindwing beneath distinctly green, the marginal band being often interrupted. — f. **juba** *Scddr.* has above somewhat broader darkened margins of the wings; beneath the apex of the forewing is more darkened, the spots of the hindwings are less coherent. — f. **nevada** *Scddr.* (180 g) is smaller, above the ♂ is of a deeper yellowish-red, the margins are less darkened; beneath the spots of the hindwing are very small on a greyish-green ground. — f. **idaho** *Edw.* (180 g) is a very light form in which the marginal darkening is reduced almost to a marginal line; the hindwing is beneath light yellowish-grey, the small light spots are little prominent. — f. **colorado** *Scddr.* (180 g) on the contrary is very much more darkened, also the basal area. Hindwing beneath dark greenish-grey with angular, torn, light spots. — f. **columbia** *Scddr.* (180 h) is above almost just the same as beneath, but quite light sand-coloured yellow, almost unmarked, still lighter than *idaho*. — f. **oregonia** *Edw.* (180 h) resembles *manitoba* above, but the ♀ is much lighter and more similar to the ♂, beneath light yellowish-grey as *idaho*, with a very

- assiniboia*, light apex of the forewing and black basal markings. — f. **assiniboia** *Lyman*. are the eastern specimens from
laurentina, Regina with a very light yellowish-green under surface. — f. **laurentina** *Lyman*. the dark brown form is called,
manitoboides, in case the above mentioned name of f. *manitoba* is to refer to the yellowish-green *assiniboia*. — f. **manitoboides**
Fletcher. is smaller than *manitoba*, of a bright tan-colour, with a very broad dark brown margin. Ontario.
- sassacus*, **E. sassacus** *Harr.* (180 h) is hardly discernible above from the forms of *manitoba*; the ♀ is larger, the
marginal shading darker and more extensive. Beneath the wings are light yellowish-red, the spots above scarcely
lighter, the basal area of the forewing spotted black. From New England to Georgia, to the west as far as
dacotae, Colorado. — The remarkably stout, green larva lives on herbs. — f. **dacotae** *Skinn.* has the dark markings almost
extinct, the ground-colour is paler. The ♀ on the contrary is quite dark with small light spots. South Dakota,
Iowa.
- harpalus*, **E. harpalus** *Edw.* is very closely allied to *sassacus*. Forewing in the disc and at the costal margin
reddish-yellow, light brown at the base and distal margin, hindwing the same. Beneath pale reddish-yellow,
forewing at the proximal margin yellowish, at the apex ochreous, at the base black. Hindwing ochreous-yellow
in the disc an indistinct, lighter, narrow, bent band and a cellular spot. The ♀ is lighter, the brown colour con-
fined, with a light submarginal band. Beneath the light band of the hindwing is more distinct. From Nevada.
- pawnee*, **E. pawnee** *Dodge* (180 h, i). Large, yellowish-red with a moderately broad smoky margin and white
fringes. The ♀ is darker, only basally and at the costal margin ferruginous-yellow with whitish spots. Beneath
montana, very dull reddish-yellow, in the ♀ more olive on the hindwings with a little lighter spots. Montana. — f. **mon-**
tana *Skinner* is above and beneath darker, broadly bordered with blackish brown, hindwing beneath with a
postdiscal row of yellow spots. Colorado.
- ottoe*, **E. ottoe** *Edw.* (180 i) is a very large, very light reddish-yellow species with very narrowly smoked
margins and also in the female scarcely darkened wings. The under surface is quite monotonously light reddish-
yellow or Isabel-coloured without any marking, only with a black-marked basal area of the forewing. From
amanda, Kansas and Nebraska. — f. **amanda** *Plötz* (180 i) is a form with a broad black distal margin from an unknown
habitat.
- lasus*, **E. lasus** *Edw.* above entirely resembles *ottoe*. Beneath the apex and costal margin of the forewing,
and the hindwings are light yellow with a green tint, the base of the cell and the proximal margin are black,
the cell otherwise reddish-yellow, an oblique discal row and 3 subapical spots are white. Costal margin of
hindwing speckled with brown, subcostal and median veins of a clear white; a postdiscal, rectangularly flawed
band of white spots is distally partly bordered with black. From South Arizona.
- cabelus*, **E. cabelus** *Edw.* is likewise very similar; the forewings are somewhat more broadly bordered with
brown, with 2 or 3 very small subapical dots. The hindwing is beneath reddish golden yellow with some minute
lighter spots, one in the lower cell-end, 2 or 3 postdiscally; a small one may also be yet near the distal margin.
Nevada.
- napa*, **E. napa** *Edw.* (= *dacotah Edw.*). We unfortunately had no access to the description of this species.
metea, **E. metea** *Scddr.* (= *riddingsii Reak.*) (180 i). Here also the ♂ is similarly marked as the ♀-forms,
of a dull greyish-brown with a reddish-yellow postdiscal band, subapical dots on the forewing and small diffuse
spots on the hindwings. The under surface is darker brown than above, the light macular markings ivory-
coloured; the hindwing exhibits near the base another bent band of white spots. From the Atlantic States.
- uncas*, **E. uncas** *Edw.* (180 k) is a larger species with long wings, the ♂ reddish-yellow with a long black
stigma, smoky margins and an especially broad dark apex of the forewing with 4 whitish spots therein. The
♀ is particularly large, dark brown with whitish spots being more reddish-yellow towards the proximal margin
and on the hindwing. Beneath the hindwing is greenish-grey with bright pearl-coloured spots which are proxi-
mally and distally bordered by a darker olive and spotted so. Pennsylvania to Montana and Colorado.
- attalus*, **E. attalus** *Edw.* (= *seminole Scddr.*, *slossonae Skinner*) (180 k). Similar as *metea*, but larger, darker,
the macular markings more distinct with a long, wedge-shaped, reddish-yellow cellular spot; the ♀ is larger
and darker. Beneath the hindwing is dull brownish-grey, the light spots are lighter grey. From the southern
Atlantic States to Florida and Texas.
- yuma*, **E. yuma** *Edw.* Above uni-coloured ochreous-yellow, without spots, with a long, narrow, almost
straight stigma; only the costal margin of the hindwing is darkened. Beneath still lighter yellow, base of fore-
wing blackish. Described according to 1 ♂ from Arizona. Expanse of wings: 1,3 inch.
- carus*, **E. carus** *Edw.* very much resembles *Chaereph. rhesus* (180 e) above, but it is easily discernible by the
♂ stigma, less purely white fringes and a different under surface which is brown with the costal margin of the
forewing and the proximal margin of both wings being dusted yellowish-white, as well as a narrow, similar
distal margin; of the same colour are the veins; all the spots above are more distinct and larger. From West
Texas.
- licinus*, **E. licinus** *Edw.* Above blackish-brown with a large, reddish-yellow discal spot, some postdiscal and
3 subapical small spots, hindwing with a large, reddish-yellow, triangular discal spot. Beneath brown, at the
costal margin of the forewing and disc of hindwing tinted reddish-yellow, the spots of above being whitish
here. Hindwing with a rectangularly bent line of white spots behind the cell, and 2 cellular dots. From Texas.

E. morrisonii *Edw.* (180 k) is easily recognized by the scent-scale stripe being far prolonged towards the apex by black spots; also in the ♀ this band-shaped, dark marking is very conspicuous. Beneath light reddish-yellow, marked ferruginous-brown with a black base of the forewing. Hindwing of a deep ferruginous-brown with a silvery white cellular stripe and a white, postdiscal macular band. Colorado, Arizona and Mexico. *morrisonii*.

79. Genus: **Atalopedes** *Scddr.*

Like *Erynnis*, but the terminal joint of the palp obtuse and hidden. Veins as in *Hylephila*.

A. campestris *Bsd.* (= *huron* *Edw.*, *kedema* *Btlr.*) (180 k, l) is well distinguished by the very broad stigma and a broad, blackish-brown margin. The dark ♀ shows postdiscal light spots. Beneath much lighter, the spots only feebly traceable. Atlantic States, Arizona, California, Mexico, Guatemala, Costa Rica, Colombia. *campestris*.

A. flaveola *Mab.* resembles the preceding, but it is smaller. Light reddish-yellow, on the forewing with a broad blackish-brown distal and costal margin; 3 subapical, small streak-shaped spots, 2 postcellular, small spots separated afar, below them a long, notched out spot and 2 more below it, the three lower ones touching the large, oval, black scent-spot. Hindwing with a broad dark margin, the disc reddish-yellow, darkened by grey, bordering on 3 lighter yellow spots. Beneath yellow, marked as above, hindwing greyish-yellow, at the proximal margin yellow with 5 lighter postdiscal spots. The ♀ is lighter, in the disc more brownish. Expanse of wings: 26 to 27 mm. Porto Cabello. *flaveola*.

A. mesogramma *Latr.* (= *canaxa* *Hew.*) (180 l) is an uncommonly large, deviating species. Above in the ♂ reddish-yellow, in the ♀ more spotted whitish. Easily recognizable by the hindwing beneath being marked with a broad white band and a small cellular spot before it; in the ♂ it is slightly tinted yellow. Brazil, Cuba. *mesogramma*.

80. Genus: **Thymelicus** *Hbn.*

Likewise very closely allied to the genus *Hylephila* and not different in the veins. Palpal terminal joint very short, scarcely visible, bent forward. The ♂ scent-scale stripe consists of 2 rows of dull black scales, the distal one being linear, the proximal ones somewhat bent, between them scales of a somewhat leaden lustre.

Th. vibex *Hbn.* (= *praeceps* *Scddr.*, *lumida* *Mschlr.*, *golenia* *Mschlr.*, *stigma* *Skinner*, *combinata* *Plötz*, *zenckeii* *Plötz*) (181 a). Above reddish-yellow, towards the margin broadly darkened, with wedge-shaped, black internerval spots on the forewing; the broad stigma rests on a black spot which is towards the apex continued beyond it. Beneath lighter yellow, base of forewing black, hindwing with minute spots. Central America, Mexico, Colombia. *vibex*.

Th. sulfurina *Mab.* (= *catilina* *Plötz*) (181 a) is similar, of a light sulphur-colour, the long, black oblique stripe of the forewing coherently extending in the shape of a band to the apex. Hindwing darker with but few yellow spots. Beneath the hindwing is strewn with a greenish-grey. Brazil, Cayenne. *sulfurina*.

Th. phormio *Mab.* is as large as *vibex*. Forewing yellow, at the apex and distal margin black with a black oblique band as far as the inner-marginal vein at the base; costal margin yellow. Hindwing red-brown, in the disc yellow. Forewing beneath as in *vibex*, but more yellow, distal margin almost quite yellow. Hindwing yellow with a series of 5 black dots and before it 3 or 4. Brazil. *phormio*.

Th. brettus *Bsd. & Lec.* (= *wingina* *Scddr.*, *unna* *Plötz*, *margarita* *Plötz*) (181 a) is similar to *vibex*, but much lighter, the marginal darkening almost absent, only the wedge-shaped spots before the margin being present; hindwing quite reddish-yellow with a black distal margin, very much like *H. phylaeus*. Beneath discernible by darker and larger spots. The ♀ is quite dark brown with very small reddish-yellow spots on the forewing. Atlantic States. Larva on herbs. — f. **brettoides** *Edw.* (= *clara* *Plötz*) (180 k) is very much lighter with a very narrowly darkened distal margin, especially the ♀ has much larger, yellowish-red spots. Beneath greyer with only very small punctiform spots. California. *brettus*, *brettoides*.

Th. mystic *Scddr.* (181 b) above very much resembles *E. morrisonii* by the long extent of the black oblique spot; also the ♀ is similar. Beneath reddish-yellow at the costa and basal area of the forewing; the rest and the hindwing ferruginous-brown with light spots, inner-marginal part light brown. Atlantic States. *mystic*.

Th. erynnioides *Dyar* is above yellowish-red, at the base blackish and with a broad black distal margin with 3 small, reddish-yellow subapical dots therein; the stigma is broad, somewhat bent, above bordered with a deep black, beneath spotted black; hindwing reddish-yellow, narrowly bordered with black. Beneath the hindwing is reddish-yellow, at the proximal margin lighter with a straight row of white spots through the middle, one below the cell, one in the cell-end and one above it, the lower and upper spot being proximally bordered with black. In the ♀ the hindwing beneath is more greenish-yellow, only at the proximal margin reddish-yellow, the white spots small, but all around bordered with black. California. *erynnioides*.

- magdalia.* **Th. magdalia** *H.-Schöff.* (181 b) is a smaller species, above bright reddish-yellow, in the inner-marginal area somewhat darkened, with narrow black borders and costal margin. The δ is darkened at the cell-end. Beneath reddish-yellow, forewing in the submedian space close to the anal angle black; the ϕ is more intensely strewn with a yellowish-green. From Cuba.
- chusca.* **Th. chusca** *Edw.* Above reddish-yellow, with narrow blackish-brown, proximally dentate distal margins, the teeth on the forewing opposite the transverse vein absent. Scent-stripe velvety black, thick, towards the base convex, here at the lower end with a black spot, distally a small dark spot. Beneath light yellow, unmarked, hindwing more ochreous. From Arizona.
- draco.* **Th. draco** *Edw.* (181 c). Blackish-brown, at the proximal margin broadly haired olive, only in the costal-marginal part and in some postdiscal and subapical small spots reddish-yellow; disc of hindwing irregularly spotted reddish-yellow. Fringes of hindwings yellowish-white. Beneath the hindwings are greyish-brown, the spots light sulphureous. Colorado.
- siris.* **Th. siris** *Edw.* is allied to *mystic* (181 b). Forewing above reddish-yellow, apex and distal margin as far as the cell and the whole hindwings dark brown; small, reddish-yellow postdiscal and subapical spots on the forewing; behind the narrow, bent stigma a dark brown spot. The hindwing exhibits in the disc an indistinct, reddish-yellow, narrow band. Beneath darker brown, the spots more distinctly yellow. The ϕ is larger, without the reddish-yellow discal colour of the δ , the spots clearly reddish-yellow, especially on the hindwings. Beneath almost cinnamon-coloured. Mount Hood.
- mardon.* **Th. mardon** *Edw.* (181 b) is above light greyish-brown, scaled yellow with a more distinctly reddish-yellow costal part of the forewing and traces of such subapical and postdiscal small spots. Beneath light grey, more or less strewn with yellowish, the spots of above repeated whitish, besides a bent macular band in the middle of the hindwing. Oregon, Washington.
- athenion.* **Th. athenion** *Hbn.* (181 c) is in the δ sex above uni-coloured blackish-brown with the broad stigma behind which there may appear very indistinct light spots which are very distinct in the ϕ . Beneath duller greyish-brown, spotted lighter on the forewing. Hindwing violetish-grey with a dark brown discal band, costal-marginal and distal-marginal spots. Mexico to Brazil.
- bahiensis.* **Th. bahiensis** *Schs.* is dull brown, cell of forewing ferruginous-brown, as well as a stripe at the base of the costa and small stripes above the cell-end, 3 small subapical spots and 2 small spots near the middle of the distal margin, as well as lighter shades behind the stigma; the disc of the hindwing is also ferruginous-brown, parted by the darker veins. Beneath the same, but of a duller colouring. Expanse of wings: 23 mm. Bahia.
- dares.* **Th. dares** *Plötz* (181 c) seems to be very similar, so that both may in certain cases be comprised as *dares*. According to the figure, only the small spots at the middle of the distal margin are absent and the under surface is lighter, more yellowish-grey, strewn with ferruginous-brownish, with a blackish inner-marginal ray being thickened towards the anal angle. From Brazil and Bolivia.

81. Genus: **Polites** *Seddr.*

Antennae and palpi as in *Hylephila*, also the veins. The δ stigma consists of a somewhat bent stripe of reverted black scent-scales, below and outside of it with a spot of similar, flatter scales.

- coras.* **P. coras** *Cr.* (= *peckins Ky.*, *wamsutta Harr.*) (181 c, d) is a smaller, squat species, blackish-brown, in the basal and larger costal-marginal half with small subapical and postdiscal spots; also on the hindwing there is a broad postdiscal band of spots, the second from above being very long, proximally and distally projecting from the row. The ϕ is without the reddish-yellow basal half. Canada to Virginia, Kansas and Iowa.
- baracoa.* **P. baracoa** *Luc.* (= *amadis H.-Schöff.*, *myus French*) (181 d) is above reddish-yellow, at the margin olive-brownish with a similar longitudinal spot behind the cell to the margin and from the proximal margin on both sides of the stigma; hindwing unmarked, fringes ochreous-yellow. In the ϕ only the costal margin is broadly reddish-yellow and 2 small postdiscal spots. Beneath of a very dull colouring with a somewhat lighter postmedian macular band. Florida and Cuba.
- sabuleti.* **P. sabuleti** *Bsd.* (= *genoa Plötz*) (181 d) looks above like a small, squat *H. phylaeus* with more darkened margins, especially the hindwings are bordered darker. Beneath lighter with still lighter spots being proximally and distally bordered by oblong black spots. California.
- chispa.* **P. chispa** *Wright* (181 d) is only half as large, above still more broadly bordered with dark, so that the wedge-shaped spots are less prominent. The under surface is purely olive-grey with a distinct, coherent, whitish postdiscal band of the hindwing without the black spots of the preceding. California.
- ignorans.* **P. ignorans** *Plötz* (181 e) is apparently allied to *chispa*, the colour is a purer golden yellow, the black margin of the hindwing very broad. Beneath the hindwing is darker, almost blackish-brown, the light postdiscal band similarly shaped as in *coras*, with a fine light anteterminal line. Venezuela.
- winslowi.* **P. winslowi** *Weeks* is doubtfully placed here. Above dark brown, towards the base reddish yellowish-brown, in the disc golden brown, stigma black. Hindwing dark brown, in the disc tan-coloured, at the proximal

margin haired golden brown. Beneath tan-coloured, basally black, at the proximal margin drab. Hindwing almost golden orange, towards the proximal margin darker, with a dark brown marginal line. Expanse of wings: 28 mm. Venezuela (Suapure).

P. lina Plötz (181 d) is a very dark species; in the ♂ scarcely lighter spots project on the forewing, *lina*. the fringes are contrasting reddish-yellow; the ♀ is more distinctly spotted reddish-yellow, the hindwing also exhibits a rufous postdiscal spot into which a black longitudinal ray extends from the cell. Hindwing beneath yellow with oblong black marginal and discal spots. Colombia.

82. Genus: **Catia** G. & S.

Antennae half as long as the costal margin, club stout and short with a pointed, slender, bent apex; palpal terminal joint stout, conical, upturned. Veins as in *Thymelicus*. The ♂ scent-scale spot consists of 4 parts: an oval velvety spot on the median between and often yet behind the rise of the median veins, on the base of the submedian a small roundish spot, between both there is a broad, grey scale-stripe, and finally another larger spot of modified scales. Middle and posterior scales strongly spined.

C. druryi Latr. (= pustula Hbn., otho Bsd., egeremet Scddr., aetna Scddr., ursa Worth) (181 e) is *druryi*. very similar to *Thymelicus athenion* (181 c), blackish-brown with a black stigma: on the forewing the costal margin, sometimes the cell, a discal spot behind the cell, and 3 subapical dots reddish-yellow; also the hindwing often exhibits extinct discal spots. Beneath reddish-yellow, in the proximal half blackish-brown with 2 or 3 postcellular spots; hindwing with a row of light yellow dots near the distal margin. Eastern States, Georgia, Mexico to Brazil. — The green larva with its brown head lives on *Sisyrinchium* and changes into a green pupa.

C. ophites Mab. is larger than *druryi*. Forewing orange, at the apex and distal margin black with *ophites*. an oblong-quadrangular inner-angular spot as far as the stigma which extends in a black oblique band to the base; from the cell-end a black stripe extends to the margin. Hindwing the same, at the costal margin darkened, as well as at the anal angle. Beneath reddish-yellow, the base of the forewing and spot of the proximal angle are black, the proximal margin itself whitish. The ♀ is similar, more broadly bordered with black, beneath redder. Brazil, Antilles.

C. pudorina Plötz (= minaya Schs.) (181 e) is closely allied. Wings dark brown, fringes grey; forewing *pudorina*. with an indistinct, very small, light spot behind the lower cell-angle, reddish-brown scales at the base of the costal margin and an olive-haired proximal margin; the hindwings are haired the same. Beneath the forewing is blackish with a grey proximal margin and a red-brown costal margin and apex; beside the small spot of the upper surface there is below it another one; hindwing reddish-brown with a dark discal shade and a light cellular spot before it; before the distal margin a lighter shade. Expanse of wings: 27 mm. Tijuca.

C. jobrea Dyar (181 e, f) is above bronze-black; two thirds of the costal margin are broadly reddish- *jobrea*. yellow, as well as 3 small subapical spots; postdiscal spots as in *pudorina*, but more distinct. Hindwing in the disc lighter, reddish-yellow, with traces of 2 or 3 small spots behind it. Beneath the forewing is reddish-yellow above the blackish proximal margin; spots as above; hindwing yellow, dusted with reddish-yellow, with a faint, light postdiscal band. In the ♀ the reddish-yellow costal margin is absent. Mexico (Guerrero). The species was recently declared to be synonymous with *otho* = *druryi* by the author himself!

C. misera Luc. (= mago H.-Schöff.) (181 e) is larger, in the ♂ much darker, the light spots scarcely *misera*. visible, the costal margin dark; the ♀ with very small yellow postdiscal spots. Beneath likewise unicoloured dark, only the proximal margin of the forewing somewhat lighter, grey, and the costal margin somewhat ferruginous-yellow. From Cuba.

C. gemma Plötz (= ravola G. & S.) (181 f). Above very bright reddish-yellow with a black apex *gemma*. and distal margin and a black, postdiscal longitudinal stripe. Behind the stigma a large, grey scent-scale area. Beneath almost uni-coloured reddish-yellow. Antilles, Dominica.

C. vesuria Plötz (181 f) is perhaps a somewhat smaller darker local form of the preceding from *vesuria*. Jamaica; the distal margin is broader black, especially the hindwing is so broadly bordered with black that only a triangular, reddish-yellow discal spot remains. Beneath the hindwing is somewhat dusted olive-greenish from which a lighter yellow postdiscal band projects.

83. Genus: **Ochlodes** Scddr.

Almost like *Hylephila*: the antennal club is somewhat longer; the ♂ scent-scale spot consists of a linear stigma, on both sides is an area of differentiated scales.

O. nemorum Bsd. (= yreka Edw.) (181 f) is above reddish-yellow with a jet-black stigma and a black *nemorum*. distal margin into which the light veins extend somewhat, and a dark postcellular spot. Beneath very much duller and lighter, in the inner-marginal part of the forewing black with a large light spot. Hindwing strewn with yellowish-grey, with an indistinct light postdiscal band. California.

- sylvanoides*. **O. sylvanoides** Bsd. (= *sonora* Scddr.) (181 f, g) is very similar, of a deeper reddish-yellow, towards the margin more reddish-brown, the black margin more blurred, proximally not forming such wedge-shaped spots. Beneath the hindwing is of a purer olive-grey, the white postdiscal band is more distinct, a roundish cellular spot near the base the same. Pacific States, Colorado, Nebraska. — f. *utahensis* Skinner is larger and lighter, beneath on the hindwing spotted greenish-white. Utah, Idaho, Colorado.
- agricola*. **O. agricola** Bsd. (= *francisca* Plötz) (181 g) is smaller, lighter reddish-yellow, the hindwing much more extensively yellow with a narrow blackish margin. Beneath reddish-yellow, forewing at the proximal margin black with a large, whitish spot. Hindwing almost unmarked. California, Nevada, Washington, also reported from Mexico.
- snowi*. **O. snowi** Edw. (181 g) is a much darker and larger species. Also the ♂ is dark brown above, behind the stigma with a series of bone-coloured spots, 3 subapical dots and 2 punctiform spots at the cell-end; proximal margin haired reddish-yellow; hindwing with 3 or 4 postdiscal spots; in the ♀ all the spots are larger. Beneath red-brown, all the spots more distinct, lighter, widened towards the proximal margin on the forewing. South Colorado to Arizona and Mexico (Puebla).
- samenta*. **O. samenta** Dyar (181 g). Bronze-black, behind the stigma with 3 yellow spots, the uppermost being quadrangular, partly transparent and with 3 subapical dots. Hindwing with a postdiscal band of 3 reddish-yellow united spots. Beneath the spots of the forewings are enlarged, the lowest wedge-shaped, reddish-yellow, the disc black. Hindwing brown, the band reddish-grey, besides with a small, straight basal band, behind which there is a dark shade. Mexico (Guerrero, Guadalajara).
- leonardus*. **O. leonardus** Harr. (181 g, h). Large, bright yellowish-red species with broad black margins and apex of forewing, in the forewing 2 subapical yellowish-red, small spots, 2 more below them towards the margin. The ♀ is quite blackish-brown without the reddish-yellow basal colour with larger, light yellowish-white spots. Beneath dark brick-coloured, in the proximal part of the forewing black with large, bright yellowish-white spots. Atlantic States.
- meskei*. **O. meskei** Edw. (= *straton* Edw.) somewhat resembles *Erynnis attalus* (180 i), it is larger, above more brightly and clearly marked. Beneath uni-coloured bright orange, only at the proximal margin and base of the forewing blackish-brown; the spots of the upper surface smaller, but somewhat lighter; at the cell-end there are 2 faint, yellow, horizontal strigiform spots. Hindwing uni-coloured except 2 or 3 yellowish dots. From Texas.
- milo*. **O. milo** Edw. (181 h) is small, fiery reddish-yellow, distal margin only narrowly darkened, towards the proximal margin in long, pointed wedge-shaped spots; especially the hindwings very narrow. Beneath monotonously dull yellowish-red, almost without any marking. Oregon.
- pratincta*. **O. pratincta** Bsd. (181 h) is above almost the same, the margin a little broader and darker. Beneath more yellowish-grey with an indistinctly lighter marking, particularly a pointedly broken postdiscal band of the hindwing. California, Washington.
- verus*. **O. verus** Edw. is allied to *agricola*. Above yellowish-red with a blackish-brown distal margin, being broad on the forewing, narrow on the hindwing; the subapical dots indistinct; at the upper end of the stigma there is a blackish-brown spot extending to the dark margin. Beneath bright reddish-yellow, forewing at the base and in the place of the stigma black, the spots of the upper surface hardly visible; hindwings entirely unmarked. The ♀ is lighter, the spots are more distinct, semi-diaphanous. Expanse of wings: 1 inch. California (Havilah).

84. Genus: **Limochores** Scddr.

Antennal club strong and long with a short, reverted apex; palpal terminal joint short, obtuse. The linear scent-organ extends from the rise of the upper median vein to the submedian. Scarcely to be separated from *Ochlodes*.

- bimacula*. **L. bimacula** Grt. & Rob. (= *acanoetus* Scddr., *illinois* Dodge) (181 h) is a large, blackish-brown species; on both sides of the long, narrow scent-scale stripe the ground is lighter reddish-yellow; collar haired ferruginous-brown. Beneath on the duller greyish-brown forewing the costal margin and cell are reddish-yellow, behind it there are 2 whitish spots. The dark grey hindwing is strewn with ferruginous-yellowish. From the Atlantic States.
- pontiac*. **L. pontiac** Edw. (= *conspicua* Edw., *orono* Scddr.) (181 h) is smaller, the reddish-yellow ground very much more extensive, occurring also in the disc of the hindwing. The ♀ exhibits on the forewing a bone-coloured, on the hindwing a reddish-yellow macular band. Beneath light reddish-brown, the spots only indistinctly lighter. Atlantic States.
- manataaqua*. **L. manataaqua** Scddr. (= *cernes* Harris) (181 i). Above olive brownish-grey, on both sides of the stigma and at the base of the costa reddish-yellow; the ♀ is blackish-brown with bands of bone-coloured spots. Beneath light grey with a postdiscal light macular band on the forewing; on the hindwing the spots are more separated, in a slightly bent row. New England and Canada to the west as far as Nebraska. — f. *lidia* Plötz (181 i) is above darker, without a reddish-yellow costal area, beneath the hindwings are more yellowish-red.
- yehl*. **L. yehl** Skinner (181 i) is bright reddish-yellow, at the distal margin and apex broad and deep black, in the latter with 2 small reddish-yellow subapical dots and a dark subcostal stripe. Beneath lighter, hindwing

monotonously light cinnamon-coloured with 4 round yellowish spots arranged in a semicircle, and a small spot near the base of the cell. From Florida.

L. dion *Edw.* looks above very much like the following *arpa*, but it is discernible by the hindwing showing on its dark reddish-yellow ground a light reddish-yellow wedge-shaped streak in the inner-marginal third, whilst in *arpa* it is equably dark. From Canada to Nebraska. *dion.*

L. arpa *Bsd. & Lec.* (181 k) resembles a very large, dark *bimacula*; the bright parts on both sides of the stigma are more olive, not so reddish yellow. Beneath the hindwing is of a purer ferruginous-yellow. Golf States. *arpa.*

L. palatka *Edw.* (= *floridensis* *Plötz*) (181 k) is very large, yellowish-brown, broadly margined with black, with a comparatively small, narrow stigma and small black strigiform spots behind the upper cell-angle. The blackish-brown ♀ has smaller, separate postdiscal spots than the following *byssus*, whereas the whole disc of the hindwing is reddish-yellow. Beneath as above, but duller, the hindwing uni-coloured greenish-brown or reddish-brown. Only in Florida, from the Indian River. *palatka.*

L. byssus *Edw.* (181 k) is very similar, the scent-scale stripe is much longer; the distal margin of the hindwing is not so sharply defined as in *palatka*, but gradually passes over into the yellowish-red, greenish reflecting discal colour. The ♀ has more coherent, larger macular bands, whereas on the contrary the hindwing only shows some minute, diffuse postdiscal spots. Beneath orange-red, base and proximal margin of forewing black. Florida. *byssus.*

L. cernes *Bsd. & Lec.* (= *ahaton* *Harr.*, *taumas* *Seddr.*, *themistocles* *Plötz*) (181 k) is smaller than *manataqua* and stouter, but it is otherwise very much like it. Above reddish-yellow, in the ♂ mostly only at the costal-marginal part, but the reddish-yellow colour may also extend farther towards the proximal margin. The ♀ is dark brown with a light yellow postdiscal band and 3 small subapical spots. Beneath the hindwing is light brownish-grey with a hardly visible, lighter macular band behind the cell. *cernes.*

L. aurinia *Plötz* (181 k) is much darker coloured, the basal part dark yellowish-brown, tinted olive-greenish, the whole distal half of the wing blackish-brown. Disc of the hindwing reddish-yellow. Beneath duller ferruginous-brownish, forewing in the basal part of the proximal margin black. Jamaica. *aurinia.*

85. Genus: **Euphyes** *Seddr.*

Antennal club thick and long with a short turned down apex. The obtuse palpal terminal joint projects a bit from the hair of the second joint. The shape of the wings is somewhat longer owing to the longer proximal margin of forewing. Stigma similarly placed as in *Limochores*, but thicker, glandular.

E. metacomet *Harr.* (= *rurea* *Edw.*) (182 k) looks above like *Th. athenion*, uni-coloured blackish-brown with the black stigma, beneath the same, though somewhat lighter. The ♀ has 2 semi-transparent, small subapical spots and 2 similar ones behind the lower cell-angle. Beneath the hindwing is light brown or purple-brown with traces of small, light postdiscal spots. United States to Canada. *metacomet.*

E. vestris *Bsd.* (= *kioyah* *Reak.*, *osceola* *Lintn.*) is regarded by DYAR as the typical form of *metacomet*; it is scarcely different, with a slight reddish reflection towards the base and proximal margin. California. *vestris.*

E. verna *Edw.* (= *pottawattomie* *Worth.*, *velutina* *Plötz*) (182 a) differs from *metacomet* by whitish, semi-transparent spots behind the stigma, subapically, and a similar longitudinal streak in the cell. Beneath lighter, more reddish, on the hindwing with a bent row of small light postdiscal spots. Atlantic States. *verna.*

E. osyka *Edw.* (182 a) looks above like *metacomet*, behind the stigma we see traces of a reddish-yellowish lighter part. Beneath quite monotonously greyish-brown. Golf States, Indiana. *osyka.*

E. menopis *Schs.* Blackish-brown with a black stigma, in the basal half olive-ochreous, at the costal margin yellow, with a yellow spot in the upper cell-end, 3 longish, yellow, small subapical spots and a yellow shade behind the stigma. Hindwing haired olive with some postdiscal, faint, ochreous-yellow patches. Beneath the forewing is black in and below the cell, distally reddish-brown, the spots lighter, at the anal angle a black nebulous spot. Hindwing yellow, at the proximal margin dark grey, basal and marginal areas reddish-brown; an antemarginal, irregular row of dark spots, also basally and in the disc, those below the cell and at the distal margin being violet, the others red-brown. Expanse of wings: 22 mm. Peru. *menopis.*

86. Genus: **Oligoria** *Seddr.*

Antennae and palpi as in the preceding. Chiefly separated by the absence of the scent-scale stripe in the ♂.

O. maculata *Edw.* (= *deleta* *H.-Schäff.*) (181 a). Above brownish-black with a very small, hyaline subapical and 2 postdiscal spots which are larger in the ♀. Beneath just as dark brown, forewing with a whitish *maculata.*

inner-angular spot, hindwing with 3 small discal spots, the uppermost being farther remote, near the costal margin. Southern Atlantic States. Perhaps also *grossula* H. Schöff. belongs to it as a synonym.

87. Genus: **Poanes** Seddr.

Antennae shorter, club thicker than in *Oligoria*. The second palpal joint very much hairily scaled, terminal joint pointed. ♂ also without a stigma.

massassoit. **P. massassoit** Seddr. (182 a) looks in the ♂ above almost like *Mastor bellus*: blackish-brown with yellow fringes. Beneath at the costal margin and distal margin bordered with reddish, with 3 light subapical and 2 or 3 postdiscal small spots, hindwing reddish-yellow bordered with reddish-brown. The ♀ has on the forewing the spots also above, and on the hindwing 3 or 4 postdiscal spots, 2 of them far towards the costal margin. Beneath the hindwings are greyer though very variable. — f. *suffusa* Laurent is beneath dusted darker grey. Atlantic States, Colorado.

88. Genus: **Poanopsis** G. & S.

Distinguished from the preceding genus by shorter, broader wings, a shorter and thicker terminal joint of the palp and a scent-scale stripe extending from the rise of the upper median vein to the submedian. Only 1 species:

puxillus. **P. puxillus** (= pupillus Plötz?) (181 a). Yellowish-brown, fringes whitish-grey; forewing with 2 subapical dots and 2 white hyaline spots in the disc between the upper median and middle radial vein and one at the cell-end; hindwings not spotted. Beneath more yellow, forewing marked the same as above, hindwing with a faint postdiscal macular stripe. Mexico.

89. Genus: **Paratrytone** G. & S.

Separated from *Atrytone* by the costal margin of the hindwing being clad with long hair, and a linear scent-scale stripe from the base of the upper median vein to the submedian.

rhaxenor. **P. rhaxenor** G. & S. (182 b). Blackish-brown with a darker stigma; forewing with a lunar spot between the median veins and a small one behind it, one above the submedian vein and 2 minute ones behind the cell-end, as well as 3 subapical dots, all of which are light yellow. The hindwing shows behind the middle in the costal half a similar band. Beneath brownish-red, forewing at the proximal margin blackish, spots as above; hindwing very peculiarly marked with 3 longish spots in the cell, behind it and near the anal angle beside the macular band. Mexico.

polyclea. **P. polyclea** G. & S. (182 b) resembles *Atrytone melane* (182 c), but it has a cellular spot and a very prominent stigma. Beneath the colour is quite different: greyish-black, the forewing in the proximal half darker, the spots as above; hindwing strewn with yellow, the transverse band from above very indistinctly visible. Mexico (Guerrero).

aphractoia. **P. aphractoia** Dyar (182 c) is above blackish-brown, in the cell-end there is an oblique quadrangular, yellowish hyaline spot, 3 small ones behind it subapically, and 3 postdiscal ones in an oblique line, the middle one being the largest; the stigma is all round encircled by black. On the hindwing there are in a straight line 4 yellow spots, alternatingly a large one and a small one. Beneath somewhat duller, the lowest spot of the forewing white and enlarged, disc black. Hindwing dusted with a dark red, the spots white, beside them 2 small ones at the costal margin and one in the cell. Mexico (Popocatepetl Park), taken at an altitude of 13 000 ft.

howardi. **P. howardi** Skinner (182 b). Above almost as *viator*, but with a dark brown diffuse spot behind the cell, almost flowing together with the dark distal margin. Scent-scale stripe present here, but of the same colour as the ground, therefore scarcely visible. Beneath doe-coloured, with a triangular, darkened base of the forewing; hindwing very light with 4 or 5 faintly darker, small discal spots. Florida.

aaroni. **P. aaroni** Skinner (182 b) is only half as large, the dark margins of the wings narrower, the dark spot behind the cell of the forewing absent. Beneath the forewing is black at the base, behind it lighter brown than above, the distal margin bordered with cinnamon-brown. Hindwing light cinnamon-coloured, unmarked. The ♀ is larger, lighter, the markings more blurred. Southern Atlantic States.

scudderi. **P. scudderi** Skinner has a much more prominent stigma, the dark borders of the wings are faint, otherwise very much like *howardi*. From Colorado.

90. Genus: **Phycanassa** Seddr.

Antennae short, palpi somewhat longer than in *Poanes*, turned forward. Veins as there. ♂ without a stigma.

viator. **P. viator** Edw. (182 b) is a large, reddish-yellow species with broad blackish-brown margins, very conspicuous by the absence of the stigma. The blackish-brown ♀ is in the disc and at the proximal margin

somewhat reddish-yellow, and on the forewing it has postdiscal, subapical bone-coloured spots and 2 smaller ones in the cell-end. Beneath paler, marked as above, on the hindwing besides with a light longitudinal ray from the base to the middle of the distal margin. Atlantic States.

P. psaumis *G. & S.* (182 c) is allied to the preceding, but the 2 spots between the median veins are *psaumis*, strongly angled. The under surface is much darker and more monotonous. Mexico (Jalisco).

P. azin *Mab.* is likewise very closely allied, but much smaller. Colombia *azin*.

91. Genus: **Atrytone** *Seddr.*

The antennae scarcely attain half the length of the costal margin, the club is short and thick with a short hook-shaped apex; terminal joint of the palp very short, quite abruptly ending in a short apex. Body strong, almost squat; middle and posterior tibiae strongly spined. The ♂ is without a pronounced scent-scale stripe, but there are often in its place modified and therefore inconspicuous scent-scales of the ground-colour.

A. delaware *Edw.* (= *logan Edw.*, *vitellius Streck. nec F.*) (182 c) is above reddish-yellow, towards *delaware*, the margin on the forewing broadly, on the hindwing narrowly darkened with a spot-like darkening behind the cell. The ♀ is larger, with a darkened basal half of the forewing. Beneath orange-red, at the base and proximal angle of the forewing blackened. Pennsylvania, Florida, Mexico to Guatemala. For this species the genus *Anatrytone* was established.

A. zabulon *Bsd. & Lec.* (= *erratica Plötz*) (182 c). This species and the following have brought *zabulon*, about an amazing muddle in the literature pertaining to them. It is above on the whole lighter; more sulphur-coloured, the bordering of the dark distal margin proximally on an average more dentate, more distinct. Beneath the base of the hindwing is less extensively darkened, in the yellow discal area there are particularly towards the proximal margin small brown spots. Southern Atlantic States as far as Mexico.

A. hobomok *Harr.* (= *zabulon Plötz*) (182 c, d) is above mostly more reddish-yellow, the black distal margin proximally less irregular, more blurred. Beneath the base of the hindwing is broader and more deeply darkened, dark spots in the median space are nearly always absent. — f. **pocahontas** *Seddr.* (= *quadaquina Seddr.*) (182 d) is a dimorphous ♀-form very much darkened above and beneath, above quite blackish-brown with minute bone-coloured spots. Atlantic States. *hobomok*, *pocahontas*.

A. rolla *Mab.* (= *piso Plötz*) (182 d). Above almost as *hobomok*, but the inner-marginal part of *rolla*, the hindwing is much broader black. Easily separable by the quite reddish-yellow hindwing beneath with indistinct ferruginous brownish spots, the inner-marginal area being scarcely darkened, and with a small black cell-end dot. Costa Rica, Panama to Colombia.

A. perfida *Mschlr.* (182 d) is very closely allied to *rolla*, it is more slender, with more tapering wings, *perfida*, lighter yellow, the inner-marginal part of the hindwing is not so broadly darkened, the cell-end spot of the forewing is somewhat larger. Beneath the proximal margin of the forewing is broader black, the apical part fiery reddish-yellow; hindwing yellow without any markings at all, dusted somewhat reddish. Colombia.

A. vitellius *F.* (= *insularis Mab.*, *hübneri Plötz*) (182 c) is externally quite similar to *delaware*; the *vitellius*, black veins are finely prominent, and the submedian and cellular folds are towards the base striped black. Beneath the blackening is absent at the proximal angle of the forewing, the hindwing is strewn with a greyish yellow. West Indian islands, also from Guatemala and the Amazon.

A. mella *G. & S.* is very closely allied to *perfida*, but the margins of the wings are above broader *mella*, black, besides there is an interrupted, blackish-brown longitudinal stripe along the median. Mexico to Brazil and Bolivia.

A. eulogius *Plötz* (= *mellona G. & S.*) (182 c) resembles *mella*, the reddish-yellow colour of the wings *eulogius*, is very much confined by broader margins of the wings projecting dentately or wedge-shaped on the lower median vein and above it between the veins. Beneath the hindwing is reddish-yellow, strewn with cinnamon-colour, with a lighter postdiscal band and cellular spot. Mexico, Panama, Guiana.

A. gladolis *Dyar* is allied to *mella*. Above broadly yellow, veins and distal margin blackish; on the *gladolis*, median there is an irregular, black longitudinal band, projecting at the end into the cell and from there on the middle radial vein towards the margin; hindwing in the disc reddish-yellow, veined black. The ♀ is more intensely marked black, beneath at the proximal margin of the hindwing with a broad black stripe. Expanse of wings: 32 to 36 mm. British Guiana. The larva lives on sugar-cane.

A. heberia *Dyar.* Above blackish-brown, costal margin as far as the cell-end reddish-yellow; 3 sub-*heberia*, apical and 4 postdiscal reddish-yellow spots, the lowest narrow, the spot above it rectangular, the second from above wedge-shaped. Hindwing with a yellow cell-spot and 5 postmedian, wedge-shaped spots. Beneath reddish-yellow, the inner-marginal part shaded with black, and in the disc veined black. Hindwing yellow with a broad black triangular spot before the proximal margin. In the ♀ the spots are white, larger and more quadrangular.

the hindwing beneath tinted grey. Expanse of wings: 29 to 33 mm. British Guiana. The larvae were fed on sugar-cane.

myron. **A. myron** G. & S. (182 d) entirely resembles the following *helva*, but the spots are more whitish-yellow, especially in the ♀ bone-coloured, the inner-marginal spot longer, the discal spot larger. Beneath the lowest spot is much larger and dirty white. Mexico to Colombia and Bolivia.

monica. **A. monica** Plötz (182 e) is allied to *eulogius*; above there are more yellow spots, the postdiscal spots thereby almost touch the subapical ones, also at the cell-end there is a large, bipartite, reddish-yellow spot, and the submedian spot is twice as large, distally gnawed out. Beneath at the cell-end of the forewing there is more black marking, on the hindwing the light postdiscal band is dying away towards the proximal margin, the colour is not so reddish-yellow, more olive greyish yellowish. From Brazil (Blumenau).

helva. **A. helva** Mschr. (= *sethos* Mab.) (182 e) is above blackish-brown with 3 yellowish-red, postdiscal and 3 small subapical spots, as well as a lighter longitudinal streak at the cell-end; hindwing with 2 or 3 rather indistinct small spots behind the cell and yellowish fringes. Beneath dull yellowish-red, strewn with grey, the proximal half of the forewing black with the spots as above, but lighter; hindwing with traces of a lighter postdiscal macular band. The base of the costal margin of the hindwing is above densely haired black. Mexico, Nicaragua, Panama, Colombia, Guiana, and Amazon.

melane. **A. melane** Edw. (= *vitellina* H.-Schäff.) (182 e) looks like *helva*, the yellowish-red spots are larger, the disc of the hindwing behind the middle extensively reddish-yellow; in the ♀ the spots of the forewing are bone-coloured, the spots of the hindwing reddish-yellow. Beneath the hindwing is in the basal half densely strewn with cinnamon-red, the postdiscal band more distinct and broader. California, Mexico, Guatemala, Costa

zachaeus. Rica and Panama. — f. **zachaeus** Plötz is a darker form from Surinam with above quite blackish-brown hindwings.

Note: MABILLE here mentions a form „marmorosa“. The citation added (Korr.-Bl. Zool. Mineral. Ver. Regensburg), refers however to one of the *Eudamus* mentioned on p. 853, perhaps a form of *santiago* (161 a). MABILLE has certainly mixed it up.

gala. **A. gala** G. & S. (182 e). Above as *melane*, but with 2 small spots in the cell of the forewing, the band of the hindwing being longer and inwardly curved towards the proximal margin. From Mexico.

monticola. **A. monticola** G. & S. (182 f) is easily recognizable by the sharply angled creamy white macular band of the hindwing on a deep cinnamon-red ground; forewing beneath with 2 or 3 roundish, orange postdiscal spots and 3 white subapical dots, which are above yolk-coloured like the discal spots. It differs from the very similar *niveolimbus* by dark fringes being on the hindwing very slightly speckled, and a dark costal margin. Mexico, at an altitude of 8 to 10 000 ft.

niveolimbus. **A. niveolimbus** Mab. is easily discernible from *monticola* by the white costal margin and white fringes. The spots are not yolk-coloured, but more whitish hyaline. From Guatemala.

ulphila. **A. ulphila** Pl. (182 f) is very closely allied to *monticola* and perhaps the same species. The yellow spots of the forewing are much larger and more numerous; beneath the hindwing is lighter, the white band extends with its tooth farther towards the margin and there is a cell-spot, the forewing exhibits near the proximal angle a very large, yellowish spot. Mexico.

lunida. **A. lunida** Mschr. (182 f) is similarly marked. On the dark forewing the 2 central spots are whitish hyaline, the others yolk-coloured; near the apex there are below the 3 subapical spots farther towards the margin 2 more small yellow spots. Hindwing without any markings. Beneath the forewing is as above; the hindwing dark olive-grey with a faded, broad, light postmedian band. Colombia. Figured according to a ♀ of Plötz.

augustus. **A. augustus** Plötz (182 f) is above not unlike *gala* and has a large, roundish, yellow spot in the cell-end; the postdiscal band of yellowish spots extends in a very oblique direction right towards the apex; the yellow macular band of the hindwing is long, towards the proximal margin inwardly bent, the second spot from above projects towards the margin. Beneath similarly marked as *monticola*, but the white band is darker, the ground not cinnamon-red but greyish-brown. Brazil.

urqua. **A. urqua** Schs. is above olive-brown, with a fine black marginal line and grey fringes. The forewing only shows a small, roundish, white spot behind the lower cell-angle. Beneath lighter; here we see on the forewing another small, subapical spot and a grey strigiform spot near the proximal angle; on the hindwing post-discally a hardly lighter, bent band, and a dark grey nebulous stripe along the proximal margin. Expanse of wings: 27 mm. Castro, Paraná.

paranensis. **A. paranensis** Schs. Above dark brown, lighter at the cell-end and with a light subapical streak. Hindwing with a black cell-end spot. Beneath the forewing is lighter brown, the apex grey, near the proximal angle a yellowish-grey nebulous spot; scarcely visible, small, lighter postdiscal spots in an oblique line. Hindwing light grey with a velvety black cell-spot and a similar spot below the lower median vein. Inner-marginal part broad light brown, before the distal margin a dark line. Expanse of wings: 31 mm. Castro (Paraná).

brasina. **A. brasina** Schs. Above dark brown, hindwing haired olive yellow. On the forewing between the median veins a quadrangular, small hyaline spot, a smaller spot above it and 3 subcostal dots. Beneath lighter,

on the forewing the costa and apex are reddish-brown, the proximal angle spotted whitish. Hindwing light brown, strewn with reddish-brown, especially densely at the base and costal margin, with a broad dark discal shade joining a dark inner-marginal streak near the proximal angle. Expanse of wings: 26 mm. Castro (Paraná).

A. inimica *Btlr. & Drc.* (= *lupulina* Plötz) (182 f) has above on the dark brown ground scarcely visible, minute lighter spots in the cell, postdiscally and subapically. Beneath the forewing, towards the proximal angle, is broadly yellowish, the hindwing deep cinnamon-red with 2 dentate, dark discal bands and a broad marginal band. Mexico to Panama, Colombia, Venezuela. *inimica.*

A. chingachgook *Weeks* is above dark brown with 3 or 4 ferruginous small subapical spots and 3 larger whitish postdiscal spots. Beneath the same, at the apex and costal margin tinted somewhat ferruginous-brown, the submedian area drab, towards the base black. Hindwing ferruginous-brown; from the costal angle to the middle of the proximal margin extends a light band scaled ferruginous, a similar one nearer to the base. Venezuela (Suapure). *chingachgook.*

A. argynnis Plötz (182 g) is very doubtfully placed here. Above blackish-brown with 3 subapical dots, 2 postdiscal white, in the ♀ more yellowish spots and an ochreous-yellow submedian patch. Hindwing with an extinct, in the ♀ much clearer postdiscal band of ochreous-yellow spots, the two middle spots of which project far towards the base. Beneath the hindwing is chestnut-brown like the apex of the forewing; in the disc golden yellow with a postdiscal row of silvery white spots; the spot opposite the cell and a large anal-angular spot are removed more towards the base, the former being proximally bordered by a black cell-end spot. Brazil. *argynnis.*

A. zela Plötz (182 g) is a very different species. Above yellowish-brown, on the forewing broadly bordered with black; the median black with a spot-like thickening at the lower cell-end, another black spot at the costal margin behind the cell and in the middle of the hindwing. Beneath almost the same, the inner-marginal part of the forewing broader black, the spot on the hindwing almost bipartite. From Montevideo. *zela.*

A. arogos *Bsd.* (= *mutius* Plötz, iowa *Seddr.*) (182 g). Here follow some more species being considered by other authors to belong to the genus *Phycanassa*. Above like a small *Phyc. viator* (182 b), yellowish-brown, with very broad blackish-brown margins and a very fine black cell-end streak of the forewing. Beneath the forewing is more broadly darkened in the inner-marginal area, the greenish-yellow hindwing without the black margin. Golf States, Iowa, Nebraska. *arogos.*

A. carolina *Skinner* (182 g) for which the genus *Epiphes* was established, looks above a little like *monticola* (182 f), with roundish, yolk-coloured spots, and a cellular spot on a dark brown ground. Beneath the forewing is the same, though more indistinctly marked, the costal margin is brownish-yellow; the hindwing is yellow with very small blackish-brown spots. Described from North Carolina and apparently very rare. *carolina.*

A. streckeri *Skinn.* resembles *delaware* above, but it is darker in its colour. Beneath very much like *poweshiek*; expanse $1\frac{1}{2}$ inch. Florida. The ♂ stigma is a long, narrow, black line from the median to the submedian, obliquely cutting through 2 internerval spaces; at the cell-end a distinct, black V-shaped spot. *streckeri.*

A. taxiles *Edw.* (182 g) has above a blackish-brown distal margin only half as broad. Beneath the ♂ forewing is bright yellow, at the base black, the distal margin light brown; hindwing lighter yellow, distally bordered with a light brown, near the base and in the middle traversed by irregular, light brown margins. Colorado to Arizona. *taxiles.*

A. ruricola *Bsd.* is yet placed here by different authors. But as this uncertain species has a broad black stigma, it will probably not belong hereto. Stated from California. *ruricola.*

92. Genus: **Augiades** *Hbn.*

Antennal club rather long, the hook-shaped apex slender, but rather short. Posterior tibiae with long fringes and the usual 2 pair of spurs. The linear stigma extends from the rise of the upper median vein to the submedian. The genus is preponderantly palearctic and Asiatic, but it has also some representatives in the New World.

A. librita Plötz (= *hecale* G. & S.) (182 i). Above bright reddish-yellow, bordered with black, with the broad black stigma being continued into a large, subapical black spot touching the black apex on the upper radial vein; veins striped black. Beneath the hindwing is especially towards the costal margin strewn with a yellowish grey, with a lighter postdiscal band dying away towards the proximal margin. Mexico, Guatemala. *librita.*

A. aligula *Schs.* is placed here with a proviso, because the scent-scale stripe is parted by the lower median vein. Above as the preceding, the transcellular black spot quadrangular and larger, touching the black margin in two places. Hindwing in the inner-marginal part haired olive. Beneath also like *hecale*, the transverse vein and both the median veins black, large black spots at the proximal angle, small subapical spots distinctly light yellow. The ♀ is brown, scantily haired yellowish-red, spotted yellow at the cell-end, postdiscally and *aligula.*

subapically, and below them near the margin (2 small spots); the hindwing also shows a cellular spot and a postdiscal row of yellow, oblong spots. Beneath darker than the ♂, the spots more distinct. Expanse of wings: 30 mm. Petropolis.

heras. **A. heras** *G. & S.* (182 h) is blackish-brown, the stigma inside almost lead-coloured; at the cell-end two small, reddish-yellow spots, behind them a quadrangular spot and 3 below the apex; the costal margin is densely, the basal part scantily strewn with reddish-yellow. Hindwing with a postmedian band of reddish-yellow spots. Beneath red-brown, basal half of the costal margin and submedian area blackish. Hindwing with 2 indistinct, bent bands of ochreous-yellow spots. Mexico (Guerrero).

chalcone. **A. chalcone** *Schs.* has dark brown wings haired ochreous at the base, at the costal margin and in the cell; in the cell-end there is a small, yellow spot, behind it an obtusely broken row of spots along the stigma almost to the apex; hindwing haired olive at the basal half, with a yellow cellular spot and a row of spots behind it. Beneath ochreous olive, forewing in the proximal half black, the spots darker, the lower ones larger; spots on the hindwing indistinct and smaller. In the ♀ the spots are larger and semi-transparent bone-coloured. Expanse of wings: 30 to 35 mm. Petropolis.

anita. **A. anita** *Schs.* Above brown, at the costal margin and subapically strewn with dark ochreous, with a small, yellow subapical spot; below the cell and behind the stigma dusted ochreous; proximal margin haired olive. Hindwing with a postdiscal ochreous-yellow band, behind it ochreous dusting. Beneath olive-green, forewing in the proximal-marginal half blackish, in the inner-angular part light ochreous; hindwing with a broad, white postdiscal band. Expanse of wings: 30 mm. Petropolis.

tania. **A. tania** *Schs.* Above as *anita*, but head and thorax greenish, forewing with a yellow spot at the cell-end, the ochreous dusting behind the cell only very scanty. Beneath likewise as *anita*, but with a yellow cellular spot. On the olive-green hindwing there is in the lower cell-angle a small white spot, behind it a narrow, indistinct, light postdiscal line with a white dot above the upper median vein and a larger one below the lower median vein. Expanse of wings: 29 mm. Petropolis.

turbis. **A. turbis** *Schs.* is also closely allied to the preceding; on the brown forewing only the basal half of the costal margin is narrowly ochreous-yellow and a spot-like shade behind the scent-spot; the postdiscal spots are very small, near the distal margin; in the cell-end a yellow spot, and 3 subapical dots. Hindwing basally haired olive, near the distal margin 3 very small yellow spots. Beneath ochreous-brown, marked as above, at the base of the forewing blackish, hindwing with a very small cellular spot and small spots behind it in a bent row. Expanse of wings: 28 mm. Novo Friburgo.

93. Genus: **Buzyges** *G. & S.*

Distinguished from *Atrytone* by a longer antennal club set with dentate scales. Costa of hindwing long-haired; the ♂ without the scent-scale stripe. Only one species:

idothea. **B. idothea** *G. & S.* (182 h) is a very conspicuous, easily recognizable species. Above blackish-brown with a large, yellow discal spot from near the costal margin almost to the proximal margin, the costal margin being yellow, too; 3 small subapical spots and below them 1 or 2 more. Fringes ochreous-yellow. Costa Rica.

94. Genus: **Atrytonopsis** *G. & S.*

Very closely allied to *Atrytone*, but with a distinctly prolonged apex of the forewing; hindwing at the anal angle somewhat lobate. ♂ with a narrow scent-scale stripe from the upper median vein to the submedian, extending obliquely and being somewhat sinuous and interrupted.

deva. **A. deva** *Edw.* (182 d) is a large, lustrous light blackish-brown species with an equally coloured stigma; 3 small subapical dots and 2 small spots between the median veins are bone-coloured transparent. Beneath as above, the forewing near the proximal angle and at the apex grey. Hindwing dusted grey and with a post-cellular band of small brownish-black spots; fringes of hindwings white. The ♀ has larger spots. Arizona, Mexico.

pittacus. **A. pittacus** *Edw.* (182 i) is very similar, smaller, with more numerous spots in the disc and submedian; the hindwing also exhibits a short band. Arizona, Mexico.

python. **A. python** *Edw.* (182 i) is likewise similar, the macular band of the hindwing only composed of 3 dots. The hindwing beneath is more band-like lilac-grey, more variegated. Arizona, Mexico.

hianna. **A. hianna** *Scddr.* (182 i). The ♂ looks above very much like *deva*, but it has only one small spot near the lower cell-angle beside the 3 subapical ones, the ♀ exhibiting 2. The under surface is somewhat lighter, distally greyer, on the hindwing with traces of a marginal band, otherwise as above. Atlantic Sates. — In f. *grotei* *Plötz* there appears yet a hyaline dot in the upper cell-angle, and the under surface of the hindwing is more monotonous.

A. judas Plötz (182 k) perhaps also belongs hereto. Above similar to the preceding, but distally the wings are much lighter grey, and above the 2 hyaline small discal spots there are two more below the subapical spot and farther towards the margin. Hindwing beneath very light grey with indistinct darker spots at the costal margin and below the cell. Novo Friburgo. *judas.*

95. Genus: **Choranthus** Seddr.

Very closely allied to the preceding genus and chiefly only distinguished by a somewhat different course of the scent-scale stripe not beginning from the rise of the upper median vein but more distally to it.

Ch. radians Luc. (= *magica* Plötz) (182 h). Bright reddish-yellow with a black dentate margin, a black strigiform spot at the cell-end and a broad black costal margin of the hindwing. Beneath the hindwing, except the reddish-yellow costal and proximal margins, is olive-green with yellow veins. — f. **ammonia** Plötz is a more intensely darkened form, and f. **bellus** nom. nov. (= *radians* Plötz) (182 k) is an entirely unicoloured dark olive-brown ♀ form with yellow fringes. Cuba. *radians.*
ammonia.
bellus.

Ch. insularis Mab. is closely allied, above the same, but beneath quite different, light orange, at the base of the forewing spotted black. Expanse of wings: 28 mm. St. Thomas. *insularis.*

96. Genus: **Lerodea** Seddr.

Antennal club strong, short; palpal terminal joint obtuse, bent backward. The forewings are higher because the distal margin is much longer than the proximal margin. The ♂ is without the scent-scale stripe.

L. eufala Edw. (= *florida* Mab., *dispersa* Plötz) (182 k) is above dark brown with 2 small, transparent discal dots and 3 subapical dots. Beneath the same, but somewhat paler; abdomen beneath white. Widely distributed from the Southern States through Mexico to Paraguay; Antilles. *eufala.*

L. dysaules G. & S. (182 k) differs by but one cellular spot of the forewing, and a bent, black, triangular band from the costal margin of the hindwing beneath behind the cell-end. Mexico. *dysaules.*

L. fusca Reel (= *concepcionis* Str.?) (182 k) presumably belongs hereto and looks like the preceding. Above blackish-brown, marked as *eufala*, beneath greyish-brown, in the larger ♀ more yellowish-brown. Hindwing without markings; fringes yellowish. Described from Chile. *fusca.*

L. tesera Schs. Above brown, fringes mixed with grey; forewing with the basal half of the costal margin grey; in the cell-end there are 2 very small whitish-hyaline spots above each other, 2 postdiscal ones and 3 subapical ones. Beneath the apex of the forewing is strewn with lilac, the proximal margin broad grey. Hindwing densely strewn with lilac, with a brownish spot in the middle of the costal margin, another one below the cell near the base, behind the middle a broad brownish nebulous band parted by the veins, and some indistinct antemarginal spots. Expanse of wings: 28 mm. Rio de Janeiro. *tesera.*

L. gracia Dyar. Blackish-brown with white fringes, base of forewing grey, in the cell-end a strangulated spot, 3 subapical ones and 4 postdiscal ones, the two upper ones of which are quadrangular and hyaline, the lower ones smaller and not transparent. Hindwing in the disc dusted with yellow, behind the cell in the shape of a spot. Beneath the forewing is basally black, the apex dusted with grey; hindwing strewn with grey, with a long black stripe-spot through the cell, and postdiscal traces of small white spots. Peru, in October. *gracia.*

L. orope Capr. (182 i) almost resembles a *Prenes* without a scent-stripe. Above blackish-brown, on the thorax and bases of the wings lustrous greenish, in the cell of the forewing a small, narrow, whitish stripe, behind it 2 small spots, and 2 subapical dots. Beneath light brownish-grey, in the disc of the forewing black, anally whitish, hindwing with a white cellular dot and 6 postdiscal dots. Brazil. *orope.*

L. dedecora Pl. (182 k) resembles *fusca*, above greyish-brown with 2 subapical dots and one postdiscal dot. Beneath duller greyish-brown, in the disc of the forewing black. From Venezuela. *dedecora.*

97. Genus: **Styriodes** Schs.

Antennae of $\frac{2}{3}$ the length of the costal margin; the latter somewhat convex, before the apex slightly concave, apex sharp. On the forewing the lower median vein rises from the middle of the cell, the upper one near the lower angle which sends forth the lower and middle radial veins, the latter being at the base bent upward. The ♂ scent-organ consists of a stripe below the median from the upper to below the lower median vein and a small spot above the middle of the submedian. On the hindwing the anal angle is slightly lobate. Only 1 species.

St. lyco Schs. Body and wings above blackish-brown, the scent-stripe deeper black; fringes at the ends ochreous-yellow. Beneath the wings are dark reddish-brown, the proximal margin of the forewing dark brown with a dark brown shade at the cell-end and below it. Costa Rica. *lyco.*

98. Genus: **Amblyschirtes** Scddr.

The antennae are shorter than half the length of the costal margin, club thick; palpal terminal joint projecting, erect or also short conical. ♂ with a narrow scent-scale stripe extending oblique and interrupted from the base of the upper median vein to below the submedian and in some species containing yet a short, small scent-stripe at the inner-marginal vein.

- vialis.* **A. vialis** Edw. (183 a) is a small, dark brown species with 3 small, light subapical dots. Beneath the same, towards the margin the colour is lighter. Northern United States to Florida and Texas.
- aenus.* **A. aenus** Edw. (183 a) is larger, duller, more brownish, the small spots are yellowish and also postdiscally there are 2 small spots; fringes very slightly speckled. Beneath brownish-grey, forewing marked as above, hindwing with a postdiscal zigzag-band of small white spots and one spot each at the cell-end and behind the middle of the costal margin. Texas, Arizona.
- exoteria.* **A. exoteria** H.-Schäff. (= *nanno* Edw.) (183 a). Blackish-brown, strewn with reddish-yellow, with a black stigma; beside 3 white subapical dots there are postdiscally below and behind the cell 4 spots in an oblique line, sometimes also one in the cell. Beneath as above, hindwing strewn with white; fringes white, speckled dark. Arizona to Mexico.
- tutolia.* **A. tutolia** Dyar (183 a) resembles the preceding, differing by more numerous, more oblong white spots above; also in the cell 1 or 2 whitish longitudinal patches. Beneath the anal angle of the forewing is occupied by a large whitish-yellowish spot. The hindwing is scantily strewn with yellowish and exhibits above the cellular spot another white dot near the costal margin towards the base. Fringes hardly noticeably speckled. Mexico (Guerrero).
- catahorma.* **A. catahorma** Dyar (183 a) is likewise similar, somewhat smaller, with larger white spots; between the median veins a transverse, longish spot close behind the stigma and below it another submedian one. Hindwing with a postdiscal curved row of 5 white dots; fringes not speckled, whitish-grey with a dark line before them. Beneath very light, the forewing at the costal margin and in the cell ferruginous-yellowish, the hindwing strewn more olive yellowish-grey with the spots of the upper surface. Mexico.
- folia.* **A. folia** Godm. & Salv. (183 a) is somewhat larger than *exoteria* with a large white spot at the anal angle of the forewing beneath; hindwing beneath less strewn white. Mexico.
- fluonia.* **A. fluonia** G. & S. (183 a) is allied to *aenus*, but the spots are less distinct, and the hindwing beneath is without the zigzag line of spots. Mexico.
- elissa.* **A. elissa** G. & S. (183 a) is smaller than *fluonia* with distinct white spots on all the wings beneath. Mexico (Guerrero).
- nysa.* **A. nysa** Edw. (= *similis* Streck.). Above lustrous dark brown, forewing with a cellular dot and 3 semi-diaphanous, small subapical spots. Beneath somewhat lighter, the spots as above, the cellular spot larger. Hindwing dusted with black, with small dark spots in the middle and at the costal margin, and a dark band parallel to the distal margin and single accumulations of grey scales. From Texas.
- eos.* **A. eos** Edw. Above greyish-brown with 3 white subapical dots; on the forewing the fringes are speckled light, on the hindwing almost white. Beneath brown, at the apex and distal margin of the forewing and on the hindwing dusted chalky; the spots of the forewing somewhat larger than above and increased by one. Hindwing with 3 discal and a row of postdiscal whitish punctiform spots. Texas.
- celia.* **A. celia** Skinner. Above dark smoke-coloured brown, almost black, fringes black speckled with ashy-grey. Forewing with the 3 small subapical spots forming a row from the costa. Through the middle of the wing a row of minute yellowish-white spots from the apex to the middle of the proximal margin, their number varying between 4 and 9. Hindwing without spots. Forewing beneath as above, hindwing very finely speckled with small light grey scales, in the middle of the wing a number of very small, indistinct white spots. ♀ like the ♂, but larger and above with fewer spots. As dark as *A. vialis*, *Stom. textor* etc., in the marking the most closely allied to *aenus* (183 a), but differently coloured. Texas (Blanco, Comal and Nueces Counties).
- mate.* **A. mate** Dyar from Mexico (Guerrero) was only recently described. Above black with a bronze reflection, speckled with few light scales, and light, darker speckled fringes. The under surface is somewhat more intensely speckled with white, otherwise not marked. Expanse of wings: 25 mm.

99. Genus: **Stomyles** Scddr.

Only little different from the preceding genus: the middle radial vein of the forewing is at its rise bent downward, the palpal terminal joint is longer, and the ♂ stigma is differently shaped; it consists of a scent-scale stripe below the median and parallel with it between the two median veins and another stripe above the lower median vein.

St. textor *Hbn.* (= *oneko* *Scddr.*, *waculla* *Edw.*) (183 b) is easily recognized by its peculiarly-marked under surface and not to be mistaken: greyish-brown, with somewhat lighter veins, on the forewing with one yellowish-white macular line, on the hindwing with two, being connected at the costal margin and in the middle. Southern Atlantic States. *textor.*

St. samoset *Scddr.* (= *hegon* *Scddr.*, *nemoris* *Edw.*, *alternata* *Grt. & Rob.*) (183 b). Above dark brown, the grey fringes speckled somewhat darker; in the cell of the forewing there are 2 small white dots, 3 subapically and postdiscally and at the proximal margin 3 more. Beneath light grey, forewing as above, hindwing with a white macular band, cellular spot and a larger one in the middle of the costal margin. Atlantic States. *samoset.*

St. simius *Edw.* (183 b) is somewhat larger, subapical and postdiscal spots together form a yellowish-red, subapically angular macular band. Hindwing in the disc reddish-yellow. Beneath very light, marked as the preceding, but the macular band of the hindwing is darker, the cellular spot very large, and the base of the hindwing whitish. South California, Arizona. *simius.*

St. cassus *Edw.* is allied to *exoteria* and *aenus* (183 a); forewing above brown, dusted with reddish-yellow, especially intensely in the inner-marginal area, with 3 small, ferruginous-yellow subapical dots and an oblique discal row of spots. Hindwing except the dark costal margin dark reddish-yellow, not spotted. Fringes whitish, at the veins darkened. Beneath the forewing is reddish-yellow in the discal and apical parts, at the base and proximal margin black, at the apex dusted whitish. Hindwing brown, dusted white, at the inner-marginal third reddish-yellow, spotted whitish. The ♀ is larger, darker, the spots more yellowish-white. Arizona (Mt. Graham). *cassus.*

St. tolteca *Scddr.* (183 b) resembles *exoteria*, but it has a double white cellular spot of the forewing, the oblique row of spots is more curved, the ♂ stigma different. Mexico. *tolteca.*

St. florus *G. & S.* looks very much like *Amblyscirtes fluonia* (183 a), but different by the stigma, and the under surface is darker and more monotonous. Mexico. *florus.*

St. comus *Edw.* (= *nilus* *Edw.*) (183 b). Above lustrous greyish-brown, forewing with 3 minute subapical dots, as well as 3 white spots below and behind the cell. Beneath lighter, the spots more distinct; hindwing with 9 dots, 6 in one row parallel to the distal margin, 3 near the base. Texas, Mexico. *comus.*

St. nereus *Edw.* (183 b, c) is larger than *comus*, the palpal terminal joint longer, the lower row of spots more distinct. From Arizona to Mexico. *nereus.*

St. arabus *Edw.* Above lustrous dark brown, forewing with 3 small, semi-diaphanous subapical dots, a cellular dot and 3 small postdiscal spots; fringes brown. Beneath brown, at the distal margin and apex dusted greyish-brown. Hindwing greyish-brown, in the disc brown as far as the costal margin. Described according to a ♀ taken in South Arizona in October. Expanse of wings: 1.3 inch. *arabus.*

St. fusca *Grt. & Rob.* is a small species with a somewhat protracted, pointed apex of the forewing and a rather straight distal margin. Above uni-coloured olive-blackish, in an oblique light with a slight golden reflection; fringes somewhat lighter, not spotted. Beneath strewn with golden brown, especially the hindwing strewn with a light golden colour except an olive-blackish ray before the proximal margin. Georgia, Florida. *fusca.*

St. osleri *Skinner* is similar, larger, above monotonously light brownish-black, the stigma a little more blackish. Beneath the forewing exhibits a black basal spot above bordered with reddish-yellow; hindwing on a dark brown ground strewn with white scales. Colorado (Chimney). *oslari.*

St. gallio *Mab.* Above blackish-brown, the spots from beneath merely traceable. Beneath the same, with 3 light yellow subapical dots, below them in an oblique row some more towards the middle of the proximal margin, the lowest being larger and white; costal margin with white striae; one in the middle of the cell and 2 small ones in the apex itself. Hindwing with 7 punctiform spots in a bent line, the uppermost being remote from the others, the third from above prolonged and projecting, the lowest moon-shaped; distal margin strewn with yellow, ends of veins bordered with yellow. Brazil. *gallio.*

St. pupillatus *Mab.* (183 c) is above greyish-brown, spots beneath grey or faintly whitish, fringes reddish. Beneath reddish-brown, with a postdiscal row of prolonged, small, black punctiform spots as in the *Lycaena* proximally bordered with whitish, also on the hindwing representing small eye-spots; the uppermost is the largest, the 3rd double; in the cell a greyish-black spot. Bolivia. *pupillatus.*

100. Genus: **Halotus** *G. & S.*

Different from *Amblyscirtes* by the more depressed middle radial vein of the forewing and the ♂ stigma which is double: a triangular part fills up the angle of the rise of the lower median vein, below it there is a short longitudinal stripe.

H. angellus *Plötz* (= *saxula* *Mab.*) (183 c). Blackish-brown with a darker stigma; the forewing shows 2 minute subapical dots and 2 white spots below and behind the cell. Beneath blackish-brown with the spots as above, the lower crescentiform; at the anal angle there is a dirty yellow stripe-shaped spot. Hindwing with a lighter undulate band; fringes dark yellow, spotted black. Known from Costa Rica and Panama. *angellus.*

101. Genus: **Synapte** Mab.

The only type is without the antennae. Wings broad with an obtuse apex; the characteristic mark is the course of the uppermost subapical vein very close at the costal so that they almost touch each other in the middle. Hindwings rounded; posterior tibiae slender with 2 pair of spurs. Only one species:

salenus.

S. salenus Mab. The only ♀ known looks like *Amblyscirtes fluonia* (183 a). From Colombia.

102. Genus: **Sarega** Mab.

Antennae long, club prolonged with a long apex. Palpi unknown. On the forewing the uppermost subcostal vein is nearing the costal-marginal vein, the middle radial vein is basally bent down; on the hindwing the median veins almost rise from the same place together with the lower radial vein. Posterior tibiae slender, fringed. The large ♂ stigma extending obliquely from the base of the upper median vein to the submedian consists of 2 parts and is set with large black scales.

staurus.

S. staurus Mab. (183 c) likewise resembles *A. fluonia*. Above blackish-brown with 2 above scarcely visible small subapical dots; beneath they are more distinct, the apex between the subcostal veins whitish; the upper half of the distal margin is lilac grey. Hindwing blackish-brown with a reddish-brown nebulous band from the costal angle to the proximal margin and nearer to the distal margin with another one composed of undulate striae. Colombia.

103. Genus: **Psoralis** Mab.

Antennae as in *Sarega*; the 2nd palpal joint hairy, the terminal joint thick, conical, porrect. On the forewing the middle radial vein is very much bent down, so that it almost rises at the lower. Veins of hindwings as in the preceding genus; between the upper radial vein and the subcostal and costal veins there are 3 transverse stripes of bossy black scent-scales. The ♂ has a scent-scale stripe extending from the rise of the lower radial vein to the submedian and being pointed at both its ends.

sabaenus.

Ps. sabaenus Mab. Above blackish-brown, hued somewhat reddish. 3 white subapical dots on the forewing are only visible beneath. Forewing beneath lighter in the proximal part. Hindwing reddish-brown with 2 broad, black bands, one at the distal margin, one in the middle, the latter expanded towards the costal margin and base. Ventrums white. Bolivia.

104. Genus: **Calpodes** Hbn.

Antennae remarkably short; second joint of the palp rising, last joint hidden; on the very long forewing the middle radial vein is situate as in *Psoralis*. Hindwing at the anal angle somewhat lobate, before it concave. The ♂ is without the scent-scale spot.

ethlius.

C. ethlius Cr. (= *chemnis* F., *olynthus* Bsd. & Lec.) (183 c) is a well known, very common species with oblong forewings. Brown with hyaline spots, a narrow one at the cell-end, 3 large ones behind it and 3 subapical ones. Base of wing ochreous. Hindwing with a row of 3 hyaline spots. Beneath the hindwing is violettish-grey, the spots less distinct. From the south-eastern States of North America through Mexico to Argentina and in the West Indies. — The larva, according to a water-colour painting made by SEITZ in Argentina, is green, before the pupation across the dorsum lilac-brown, watered white, the head beneath very broad, above somewhat indented, the os, a triangle above it and two punctiform spots at the sides of the frontal vesicle black. In funnel-shaped leaves of *Canna*. Pupa green, on the frons a spine-like, curved appendage; the case of the sucker projects beyond the apex of the abdomen by 1½ to 2 cm; it yields the imago in 10 to 20 days.

105. Genus: **Asbolis** Mab.

Antennae of medium length, club thick, ovoid. Palpi thick, appressed to the frons. On the forewing the upper radial vein rises on a short footstalk with the lowest subcostal vein; the middle radial vein as in the preceding genera very near to the lower ones; the median is strongly angled at the rise of the lower branch; hindwing prolonged with an oblique straight distal margin and somewhat lobate. The ♂ shows a bipartite stigma, one part extending somewhat bent between the two median veins, and from the lower one linearly to the submedian.

sandarac.

A. sandarac H.-Schüff. (= *palaea* Hew.) (183 d) is above deep blackish-brown, on the body and bases of the wings with a faint green reflection; stigma grey. Fringes of forewings ochreous-yellowish, on the hindwing white with a yellow base. Beneath more reddish, towards the base blackish with a lighter, in the larger spot near the proximal angle of the forewing. Colombia, Cuba.

A. gagatina *Mab.* is more robust, smoky black, forewings short and squat, hindwings rounded, short. *gagatina*. Disc of the forewing with a ferruginous-red reflection, fringes light brown. Beneath ferruginous brownish-black, forewing with a row of faintly greyish spots round the cell from the costal margin to the upper median vein. Hindwing with a bent ferruginous-red patch between the upper median vein and upper radial vein. Thorax with a metallic green reflection. Ventrums brown, antennae short as in *sandarac*. Brazil.

A. halomelas *Mab.* has no stigma, and may therefore not belong hereto. Hindwing longer than in *halomelas*. *sandarac*, of a deeper black colour, distal half of forewing ferruginous-brown, veins black; 3 minute, yellowish subapical dots are only to be seen with the lens, the two lower ones being transparent. Forewing beneath from the base to the cell black, hindwing with a blacker shade in the middle. Body black, without a metallic lustre, but with a slight bottle-green reflection; the two last abdominal rings are beneath yellow. Antennae $\frac{1}{4}$ longer than in *sandarac*. Fringes black. From Pebas.

106. Genus: **Zariaspes** *G. & S.*

Antennae shorter than half the costal margin. Palpi thickly scaled. Last joint conical, short, erect. Apex of forewing pointed. Posterior tibiae with only one pair of spurs. The ♂ has no scent-scale stripe on the forewing.

Z. simplex *Fldr.* (183 d) is a very small species resembling *Ancyloxipha arene* (180 c). Above uni- *simplex*. coloured pale reddish-yellow with a very fine black marginal line. Beneath the apex of the forewing is lighter yellow, the proximal margin black almost as far as the anal angle, and the hindwing is strewn with a greenish yellow except the reddish-yellow inner-marginal part. From Mexico.

Z. mys *Hbn.* (= *dukolum* *Blake*, *epictetus* *Stgr.* nec *F.*) (183 d). Above bright yellow bordered with *mys*. black, with an oblique, black longitudinal stripe being somewhat indented below the cell-end, or entirely interrupted. The ♀ is black with a yellow oblique stripe of the forewing and a discal spot of the hindwing. Beneath yellow, forewing at the proximal margin and anal angle black. Mexico to Paraguay.

Z. mytheus *G. & S.* (183 d) is larger than *mys*. Lustrous ochreous-yellow; costa of forewing towards the apex, distal margin and proximal margin as well as a narrow discocellular line blackish-brown like the costal margin of the hindwing. Beneath ochreous-yellow with a blackish-brown basal spot. The ♀ has also the hindwings bordered with blackish brown, and on the forewing an interrupted longitudinal band from the base through the cell, and a triangular spot behind it blackish-brown. Mexico (Guerrero).

Z. portensis *Mab.* is doubtfully placed to this genus. Above reddish-yellow, forewing with a narrow *portensis*. black border, at the proximal angle widened; veins black, at the cell-end widened into a black triangle. Border of hindwing black, at the costal angle very broad, from where a tooth extends to the cell-end, at the distal margin narrow, at the anal angle prolonged into 2 points; the basal part is somewhat brownish. Beneath yellow, base of forewing blackish with a dull blackish border. Expanse of wings: 28 mm. Porto Rico.

107. Genus: **Aëlla** *Mab.*

Antennae as in the preceding genus. Terminal joint of the palp slender, long and obliquely erect. On the forewing the median is inflated in its basal third as well as the first quarter of the lower median vein. Tarsi long and slender, the stout posterior tibiae with but one pair of spurs. Only one species:

A. dryops *Mab.* Small; forewing bright yellow with a black border being expanded at the apex, and *dryops*. a black longitudinal band being narrowed in the middle, widening towards the apex in a quadrangular spot with extended angles, touching the costal margin. Hindwing yellow, unmarked, only at the base somewhat blackish. Beneath yellow, strewn with whitish. From Brazil and Venezuela.

108. Genus: **Padraona** *Mr.*

Antennal club rather long with a short apex; palpal terminal joint short, slender, erect. On the forewing the middle radial vein is curved at the base, very much nearing the lower radial. Hindwing near the anal angle somewhat indented. Posterior tibiae with 2 pair of spurs. This genus containing mostly Indo-Australian representatives has also some American species.

P. epictetus *F.* (= *ferrago* *Plötz*, *eudesmia* *Plötz*) (183 e) looks somewhat like *Zariaspes mys*. Above lustrous *epictetus*. reddish-yellow, broadly bordered with black with a broad, black longitudinal stripe of the forewing, being mostly somewhat indented behind the cell-end beneath; the costal margin remains yellow. Beneath the forewing is at the costa and apex and the whole hindwing feebly dusted with cinnamon-colour; the hindwing has mostly lighter yellow veins and a black longitudinal stripe along the inner-marginal fold. Widely distributed from Mexico through South America.

P. tryhana *Kaye* is very similar; bright golden yellow with a broad black distal margin and longitudinal *tryhana*. stripe projecting towards the margin on the lower median vein and between the upper radial veins. Hindwing more extensively yellow, beneath quite uni-coloured yellow. Expanse of wings: 34 mm. Trinidad.

- lento*. **P. lento** Mab. (183 e) is somewhat larger than *epictetus* and similarly marked reddish-yellow, but the yellow bands are narrower, the costal margin is yellow only as far as the middle of the cell, the hindwing exhibits a narrow yellow band. Beneath the forewing is red at the costal margin and apex, blackish at the proximal margin and disc, instead of the band there is an oval yellow spot. Hindwing red, with yellow veins, at the proximal margin blackish-brown; below the cell there is a yellow, oblong spot. From Pará.
- hyboma*. **P. hyboma** Plötz (183 e) looks above like the ♀ of *Zariaspes mys*: black with a yellow longitudinal stripe being above indented behind the cell on the forewing, and an oval longitudinal spot of the hindwing; fringes especially towards the anal angle broadly yellow. Beneath the hindwing is peculiarly marked, light yellow with a brown longitudinal stripe parallel to the costal margin and a longitudinal stripe along the inner-marginal fold, and a brown distal-marginal band widening towards the anal part. From Minas Geraes.
- argus*. **P. argus** sp. nov. (183 e) somewhat resembles *sartia*. Above almost the same, but the hindwing is without the yellow marginal spots and the black hair-pencil. Beneath the hindwing is very different, in the disc creamy white, base and distal margin brownish, behind the cell are 2 large black spots, between them a very small one, all of them exhibiting outside a white pupil, and behind them another small black spot, between the spots the veins are ferruginous-yellow; inner-marginal fold striped black. According to a ♂ from the Coll. FASSL, from the Songo (Bolivia).
- sartia*. **P. sartia** Schs. Above dark brown, basal half of costal margin light ochreous-brown; spots light yellow, semi-transparent, bordered with a darker yellow: 3 small subapical spots, a large quadrangular spot between the median veins, a smaller one above it, and a stripe above the submedian; base and proximal margin haired ochreous-brown. Costal margin of hindwing broad dark brown, distal margin black, at the proximal margin a black hair-pencil; disc dark ochreous-brown with some small yellow spots before the margin. Beneath the forewing is black with a broad black shade at the proximal margin; disc ochreous with a velvety black spot behind the cell and a large white spot behind it, and above the latter 2 white spots and below it likewise 2, another longer one below the lower median vein. Expanse of wings: 27 mm. Petropolis.
- calcareo*. **P. calcarea** Schs. Forewing dark brown with a broad reddish-yellow longitudinal band from the middle of the submedian towards the apex, narrowing near the middle radial and widening above it, then growing narrow again and being crossed by the dark veins; hindwing with an oblique orange spot near the distal margin between the lower median and middle radial vein. Beneath light brown, with light veins; forewing in the cell and near the proximal angle black, the reddish-yellow spots darker. In the ♀ instead of the yellow band whitish spots, only the lowest being yellow and double. Expanse of wings: ♂ 30, ♀ 33 mm. Petropolis.
- imerius*. **P. imerius** Plötz (183 e) is only doubtfully placed here like the following. Above reddish-yellow with broad black margins, a black, wedge-shaped stripe through the cell and another one half as long below it. Beneath yellow, forewing at the base, as well as one spot each behind the cell and at the proximal angle black; the apical part and the whole hindwing black, with very broad reddish-yellow veins. From Brazil.
- krexos*. **P. krexos** Plötz (183 e) is similar, larger, more robust, much more broadly bordered with black, with only one broad black longitudinal stripe of the forewing, being interrupted by yellow at the cell-end. Beneath the apex and costal-marginal part of the forewing as well as the whole hindwing are chestnut-coloured, with narrow yellow veins. Described from Pará.
- rivula*. **P. rivula** Mab. Blackish-brown, forewing with a postdiscal band of 8 equally broad, reddish-yellow spots, being angled at the upper radial vein, the 2 lowest hollowed out; in the cell a spot and below the costal margin 2 streak-shaped spots. Hindwing with a round cellular spot and a light reddish-yellow median band. Fringes brown, distally reddish-yellow. Beneath the forewing is black below the cell, at the costal margin strewn with yellow, spotted as above. Hindwing with a broad median band, base strewn with yellow, the cellular spot surrounded by brown. Expanse of wings: 23 mm. Teffé.
- levina*. **P. levina** Plötz (183 f). Above black with a reddish-yellow subcostal stripe, 2 similar subapical dots, a cellular spot and 2 postdiscal ones as well as a submedian stripe; the 3 discal spots are lighter and semi-transparent. Hindwing with a large reddish-yellow discal macular band. Beneath the apex of the forewing and the hindwing are cinnamon-coloured with yellow veins. From Brazil (Rio de Janeiro).
- flavocostata*. **P. flavocostata** Plötz (183 f) is smaller, the reddish-yellow spots flown together to an oblique band, the subcostal space darkened. Hindwing with a reddish-yellow postdiscal spot and a similarly coloured median as far as the base; fringes reddish-yellow. Beneath likewise very much like *levina*, the ground more blackish-brown, not so red, the veins broader yellow. From Rio de Janeiro.
- vicinus*. **P. vicinus** Plötz (183 f) resembles *flavocostata*, but it is larger, of a more intense reddish yellow, on the hindwing with a broad postdiscal band; fringes much broader and brighter reddish-yellow, also on the forewing. Beneath extensively yellowish-reddish, in the disc of the forewing blackish, on the hindwing with some reddish-brown vein-stripes. Colombia.
- radiata*. **P. radiata** Schs. Above dark brown with a bright yellow stripe in the basal half of the costal margin, another one below the submedian and one above it, ending in a large spot. At the rise of the lower median vein there is a small round scent-spot, behind it a quadrangular one above which there is a small one in the cell, all being pupilled light yellow; another similar spot is between the median veins, another subapical

spot; before it at the costal margin yellow scales. On the hindwing the lower half of the cell and a spot behind it bright reddish-yellow, so that only a small part remains dark brown; between the median veins near the cell there is another brown spot. Beneath the forewing is black, the costal margin, apex and distal margin light brown with darker stripes between the veins which are yellow. Hindwing violettish-brown, veins light yellow; a broad, black wedge-shaped stripe is situate near the proximal margin and widens towards the anal part. Fringes black, distally grey. Expanse of wings: 30 mm. Petropolis.

P. amyrna *Mab.* is deep brown with a reddish-yellow reflection, in a certain light with a blue reflection: forewing with 3 oblong, yellowish subapical hyaline dots, the uppermost dying away. Between the lower median and upper radial vein there are in an oblique row pale reddish-yellow spots only slightly contrasting with the ground; fringes dirty grey. Hindwing not spotted, with ashy-grey fringes. Beneath brown, forewing at the costal margin and apex more reddish, of the macular band only 2 spots are visible. Hindwing with a reddish-brown reflection, a black marginal line and 4 small yellowish postdiscal dots towards the apex. Expanse of the wings: 26 mm. Described from Porto Cabello.

P. binaria *Mab.* is deep blackish-brown, in the cell with a ferruginous brown reflection, behind it with 2 whitish dots in an oblique line, costal margin and veins deeper black. Hindwing coloured the same with ferruginous yellow fringes. Beneath dull greyish-black, the spots more distinct, below the middle lighter yellowish-white, at the costal margin and veins ashy-grey. The brown hindwing is densely strewn with greyish-violet. Expanse of wings: 32 mm. Venezuela (Merida).

P. sophistes *Dyar.* Blackish-brown with an orange band along the costal margin to the cell-end, where it turns downwards and is obliquely traversed by the radial veins; another band extends along the proximal margin as far as $\frac{2}{3}$ of its length, and is united here with another band which narrows upwards, is incised at the cell-end and terminates at the lower subcostal vein. Fringes reddish-yellow. Hindwing reddish-yellow in the disc and with a reddish-yellow band at the distal margin. Beneath the forewing is reddish-yellow at the apex, otherwise as above; hindwing entirely reddish-yellow, markings from above only faintly showing through. Expanse of wings: 24 mm. Mexico.

P. inculta *Dyar.* Black, fringes at the ends reddish-yellow. Costal margin of forewing dusted reddish-yellow with an oblique postdiscal band, traversed by the veins, bent round the cell-end and broken up into 3 subapical spots; hindwing with a reddish-yellow postdiscal band and yellow dusting at the proximal margin. Beneath dusted yellow, forewing with a large yellow discal spot and yellow costal margin, in the cell a black dot, proximal margin black, towards the base penetrating into the cell. Hindwing yellow with yellow veins and a dark marginal band. Expanse of wings: 27 mm. Mexico.

P. dara *Koll.* (= *maesoides* *Btlr.*, *omaha* *Edw.*, *mingo* *Edw.*, *californica* *Scddr.*) is an insect widely distributed in Asia and having been dealt with in the palearctic part (comp. Vol. I, p. 351, t. 89 g). Above yellowish-brown, bordered with black, with an oblique longitudinal band from the proximal margin to the apical third of the costal margin. This species also occurs in the United States. For this American form SCUDDER established the genus *Potanthus*.

109. Genus: **Pyrrhocalles** *Mab.*

Antennae as in the preceding with a long apex. Forewing broad triangular, distal margin in the middle convex. Palpi ascending, broad, flatly appressed, with a slender pointed terminal joint which is very long and erect. The ♂ is without a stigma. Only one species:

P. antiqua *H.-Schäff.* (= *utha* *Hew.*) (183 f, g). ♂ above fiery orange-brown, broadly bordered with black, with a large, black postcellular spot; ♀ much darker brown with a yellow, above forked macular band behind the middle, a black discal streak on the hindwing and a lighter red-brown spot behind it. Behind the forewing is as above, the hindwing brown with a red-brown postdiscal band. Hayti, Jamaica, Cuba.

110. Genus: **Serdis** *Mab.*

Antennae longer than in the preceding genera, but they do not quite reach to the cell-end. On the forewing the median area between the two branches is very long owing to the lower branch rising near the base, the upper near the cell-end. Posterior tibiae with long fringes. The ♂ exhibits a thick stigma of a dull black colour extending from the cell-end to the base of the submedian and being divided into 4 parts.

S. flagrans *Mab.* (183 g) is above bright reddish-yellow, with a black border, which between the veins penetrates into the surface like a wedge; inner-marginal halves of both wings dusted grey; behind the cell, as a continuation of the stigma, a black spot, a similar one being pupilled reddish-yellow in the cell situate at the costal margin of the hindwing. Beneath the apex of the forewing is reddish-brownish-grey, and the greatest part of the hindwing except the broad yellow proximal margin; a postdiscal, bent, yellow band, before it a brownish-grey band. Ecuador, Bolivia.

S. venezuelae *Ww.* (= *stadius* *Plötz.*, *fulgens* *Mab.*) (183 g) is very much like *flagrans*; the margin is less broad black, the grey dusting less intense, the postcellular black spot small, hindwing without a costal-marginal spot. The ♀ is much darker with 2 large, white, postdiscal spots and 2 small ones at the cell-end. Beneath the ♂ is plainly reddish-yellow, the proximal margin of the forewing black, the hindwing dusted green, with somewhat lighter veins; the ♀ has a green apex and costal margin of the forewing and green hindwings with 2 very much bent, narrow, light yellowish bands. Venezuela.

viridicans.

S. viridicans *Fldr.* (183 h) is a large, beautiful species; above deep rufous, very broadly bordered with black, with 3 small white subapical spots and a fourth below them; costal margin olive-green like the hairing of the body; a broad black oblique stripe terminates into the broad black apex; hindwing with a broad costal-marginal spot; fringes of hindwings analwards white, otherwise ochreous-yellow. Beneath the forewing is apically and at the costal margin as well as the whole hindwings bright olive-green, at the distal margin lighter; hindwing with a straight, light, narrow transverse band and a broad black inner-marginal wedge. Colombia.

kirschi.

S. kirschi *Weym.* (183 g) is only doubtfully regarded as a different species. Above the forewing is without the postdiscal white spot behind the lower cell-end, the base of the hindwing is broader red-brown and connected with the postdiscal macular band which does not extend parallel to the distal margin, but terminates distally concavely pointed into the apex. Beneath the anal angle of the forewing is scarcely dusted black, and the hindwing exhibits 2 parallel, distally slightly concave, light green bands, the distal one of which terminates into the costal angle. Colombia.

fractifascia.

S. fractifascia *Fldr.* (183 g) resembles *viridicans* above, the black border being narrower; on the hindwing before the distal margin extends a straight or almost proximally convex, fox-coloured band which is flawed in an acute angle on the upper radial vein. Beneath as *viridicans*, but the distal white band of the hindwing forms below the costal angle a pointed tooth distally, touching the margin, the proximal band terminates distally in the lower cell-angle. Colombia, Venezuela.

111. Genus: **Trioedusa** *Mab.*

Antennal club very long, fusiform; palpi appressed, last joint conical, erect. Middle radial of the forewing as in *Psoralis* and *Calpodes*; the median strongly inflated, especially beneath; the submedian is bent and forms an angle at the place where it touches the lower end of the stigma. Posterior tibiae bare, only with terminal spurs. Scent-scale stripe tripartite, the uppermost part velvety black near the cell-end on the median, the middle one bordered with grey at the lower median vein, and the lower roundish, hairy on the submedian angle.

milvius.

T. milvius *Mab.* (183 h). Black, costal margin striped ferruginous yellow, with a narrow, oblique, reddish-yellow band extending from the 3 small subapical spots to the base of the proximal margin and widening before the stigma; hindwing with a broad discal spot, fringes likewise ferruginous-yellow. Beneath the forewing is ferruginous-yellow, the band lighter yellowish, hindwing the same, the discal spot bordered by small reddish spots. Brazil, Paraguay.

devergens.

T. devergens *sp. nov.* (183 h) is above and beneath hardly discernible from *milvius*, somewhat smaller, the wings less stretched and above all different by anatomical differences which will probably necessitate the establishment of a new genus. The median is not inflated nor is the submedian angularly flawed. The scent-organ consists of an angular part on the median in the angle where the lower branch rises, below it a roundish scent-spot and above the submedian a third one. The reddish-yellow band of the hindwing is above somewhat broader and beneath the black colour on the forewing is more intense and more extensive. Otherwise coloured and marked the same. According to 1 ♂ from Muzo (Colombia), taken by FASSL.

112. Genus: **Prenes** *Scedr.*

Antennae mostly rather short, like the last palpal joint, Forewing long, the cell of 2_3 of the length of the costal margin; middle radial as in the preceding; hindwing at the anal angle feebly lobate. The oblique, narrow scent-scale stripe which is interrupted, is in some species absent altogether. Posterior tibiae with double spurs.

nero.

P. nero *F.* (= *nyctelius* *Latr.*, *fusina* *Hew.*) (183 h) is a most extraordinarily variable species, especially in the size and development of the white band on the hindwing beneath. Above blackish-brown with a white, semi-transparent cellular spot, 3 or 4 behind it, the uppermost very small, the lowest more yellowish than the others, and 3 subapical dots. Beneath the same, but on the hindwing mostly with a white band. Head and thorax mostly greenish. — In f. **corrupta** *H.-Schäff.* (183 h) the spots are small, the hindwing shows instead of the white band above an indistinct reddish one; beneath the latter is broad, somewhat reddish. Cuba. —

*corrupta.**sylvicola.*

sylvicola *H.-Schäff.* (183 i) has the hindwing beneath in the larger costal half and the apex of the forewing suffused with steel-grey or lilac-grey, and instead of the white band of the hindwing only small, indistinct light

fulidia.

punctiform spots. From Cuba and Para. — In **fulidia** *Hew.* (183 i) the band is narrow, divided into spots. Between all these forms there exist, however, numerous transitions. Often the cellular spot of the forewing is prolonged. From Mexico to Brazil and the West Indies. — f. **conformis** *Plötz* (183 i) has beside the broad white band of the hindwing also a cellular spot beneath.

*conformis.**evadnes.*

P. evadnes *Cr.* (= *chlorus* *Plötz*) (183 i) is larger than *nero*. Forewing towards the base and hindwing strewn with dark yellow, otherwise above very similar. Beneath the apical part of the forewing and the

hindwing are dusted with a deep cerise colour, the silvery white band is broad, proximally somewhat dentate and extends farther towards the black proximal margin. Guatemala to Colombia and Brazil.

P. pauper *Mab.* (183 i, k) is above similar, but the ♂ is without the stigma, and the band on the hindwing beneath is white not silvery, at both its ends reduced to spots; the hyaline cellular spot of the forewing is small; the undulate, interrupted band beneath separates it also from *nero* to which it is otherwise allied. Mexico, Honduras, Guatemala to Colombia. *pauper.*

P. heterospila *Mab.* is allied to the preceding. Forewing with a bent band of yellow hyaline spots: 3 subapical ones, 2 small ones below them and 2 larger quadrangular ones below them, the lowest being more yellow. Hindwing unspotted. Beneath in the disc black, at the costal margin and apex reddish-brown. The hindwing is yellowish red-brown with 3 white black-margined dots, one being situate at the costal margin more remote from the others; in the cell of the forewing there is near the costal margin a small dark dot. From Peru. *heterospila.*

P. luctuosa *H.-Schäff.* (183 k) is much larger, the cellular spot reduced to a small dot, the other spots yellowish, the middle postdiscal spot distally deeply hollowed out. Body and base of wings haired brown. Beneath similar as *evadnes*, strewn with a dark red-brown, the white band proximally very convex, near the anal angle the dark ground-colour extends far into it. Brazil. *luctuosa.*

P. grapte *Drc.* (183 k) is very closely allied to *luctuosa* and also to *pauper*. In the cell-end of the forewing there is a small, oblong spot beside the usual spots. Fringes light brownish-white, base of wings and body ochreous. Beneath somewhat lighter, the spots as above, only the submedian spot larger and more blurred. The hindwing exhibits a small, round, white spot in the cell; and behind it a white, bluish reflecting band, proximally sharply defined and convex, distally blurred: it begins pointed at the costal margin and grows much broader towards the proximal margin. The distal margin is brownish-grey with brown veins. From Peru. *grapte.*

P. philippina *H.-Schäff.* (183 k) is smaller, above with an intense green reflection on the body and base of the wings; the cellular spot of the forewing is entirely absent, the spots otherwise as in *nero*. Beneath the hindwing is quite uni-coloured dark brown without a band. Panama (Chiriqui). *philippina.*

P. ares *Fldr.* (= *coscinia* *H.-Schäff.*) (183 k) resembles *philippina* above, but it is less green, with a double cellular spot of the forewing. Beneath the hindwing is lilac-grey with a broad brown discal and marginal band and a round costal-marginal spot near the base. Mexico to Brazil and the West Indies. *ares.*

P. cornelius *Latr.* (= *ocola* *Edw.*, *hecebolus* *Seddr.*, *ortygia* *Mschlr.*, *parilis* *Mab.*) (184 a) is still smaller, more insignificant, without any green, without a cellular spot, all the spots smaller; hindwing beneath with a rather indistinct band of whitish, small punctiform spots. From the South Eastern States through Mexico in almost the whole of South America as far as Peru: also in Trinidad. *cornelius.*

P. diduca *Schs.* is a very small species, above dark brown, the ends of the fringes lilac-grey. The forewing exhibits only a minute yellowish subapical spot. Beneath lighter brown, on the forewing the apex is tinted lilac like the whole hindwing, on which there is a very small yellowish spot near the cell-end, behind it a bent row of similar small spots, the lowest being the largest. Expanse of wings: 24 mm. Petropolis. *diduca.*

P. panoquin *Seddr.* (= *wimico* *Plötz*, *ophis* *Edw.*) (184 a) very much resembles *cornelius*, from which it chiefly differs above and beneath by somewhat more olive-greenish scaling, as well as an oblong white wedge-shaped spot on the hindwing beneath between the radial veins; there is often another smaller one below the median veins; the veins are somewhat lighter than the ground. Southern Atlantic States. *panoquin.*

P. panoquinoides *Skinn.* is beneath very much like *panoquin* and resembles it also above, but it is here less and more indistinctly marked. It forms the transition from *panoquin* to *Stomyles fusca* and is smaller and darker than the former, but larger and lighter than *fusca*. From Key West in Florida and Texas. *panoquinoides.*

P. errans *Skinn.* Above exactly the counterpart of *ocola*, beneath very much like *panoquin* and *panoquinoides*. Above dark brown, forewing with 2 small, yellow spots. Hindwing beneath with 3 spots, the first in the 3rd subcostal area, the 2nd in the 4th, the 3rd in the first median area. Expanse 1½ inch. California and Texas. — Larva green, the head marked black, with green feet, on herbs. Found in Sa. Barbara. *errans.*

P. vala *Mab.* (= *actor* *Mab.*, *dama* *Plötz*?) (184 a). Above blackish-brown with a yellowish reflection: forewing with a small apical dot, 2 small postdiscal spots and a very small cellular diffuse spot. Fringes yellowish. Beneath lighter brown, forewing lighter whitish towards the anal angle, hindwing with a short, bent, whitish discal band formed of dispersed scales. Expanse of wings: 26 mm. Mexico, Guatemala, Panama (Chiriqui), Brazil. *vala.*

P. valo *Mab.* is described according to but one ♀, for which reason its position is doubtful. Olive-brown; forewing with 3 hardly visible subapical dots and two whitish spots behind the lower cell-angle; fringes dirty grey. Forewing beneath lustrous grey, at the costal margin ashy-grey with an oblong-quadrangular, ash-coloured, submedian lighter part. Hindwing more brownish grey with a short, lighter postdiscal band of 3 indistinct spots. Expanse of wings: 32 mm. Bogotá. *valo.*

hemizona.

P. hemizona Dyar. Black with a blue reflection, wings very long, forewing produced at the anal angle, here with white fringes; in the cell a quadrangular white spot, a wedge-shaped one below it; behind the cell 5 in a curved row. The hindwing exhibits a white band with rounded, yellowish ends behind the cell. Beneath the same. Expanse of wings: 40 mm. Mexico.

113. Genus: **Cydrus** G. & S.

Antennal club shorter than in *Preues* with a longer hook-shaped apex. Apex of forewing prolonged, costal margin convex, distal margin concave. The ♂ shows a broad scent-scale stripe from the rise of the upper median vein to the submedian.

naevolus.

C. naevolus G. & S. (184 a). Blackish-brown, the stigma dark with large, white hyaline spots arranged as in *P. cornelius* but being much larger, especially the cellular spot which is parted by the fold. Hindwing with a yellowish, indistinct cellular spot and 4 or 5 behind it in a curved row. Beneath as above, the forewing tinted purple, the hindwing scantily strewn with yellowish, the spots more distinct; fringes white, on the ends of the veins somewhat speckled. Mexico, Guatemala, Panama to Brazil.

114. Genus: **Aides** Billb.

Antennal club stout and long. Prolonged apex of wings and veins as in the preceding genus. The ♂ exhibits an angular stigma in the angle between the rise of the lower median vein and the median, below it a longitudinal stripe and near the proximal margin a third being divided by the submedian.

epitus.

A. epitus Cr. (= *argyrina* Stgr. i. l.) (184 a, b). Blackish-brown, base of wings and body haired greenish, stigma grey. Spots yellow hyaline a cellular spot distally hollowed out, 3 spots in an oblique row behind it and 3 subapical ones. Hindwing with a yellowish apical spot. Beneath more reddish, in the basal half darker, costal margin above the cellular spot yellow. Hindwing in the disc with a large, triangular silvery spot and 1 or 2 spots towards the distal margin. Panama to Brazil.

dysoni.

A. dysoni G. & S. (184 b) is very much like the following *aestria*, but the silvery spots beneath are different: a small one is situate in the cell, 3 large ones behind it more towards the proximal margin, the middle spot being the smallest, and before the distal margin there is another transverse, crescentiform spot. Honduras.

aestria.

A. aestria Hew. (184 b) is blackish-brown with a large, double cellular spot, 3 large postdiscal ones and a very small one above it, as well as 4 subapical ones. On the hindwing there is behind the cell a double, white spot. Beneath the apex of the forewing and the costal half of the forewing are extensively cerise or red-brown; on the hindwing there is a very large silvery spot in the disc and 6 irregular, smaller ones behind it. Brazil.

elara.

A. elara G. & S. (184 b) is like *epitus*, but without subapical spots; the silvery spot of the hindwing terminates towards the costal margin into 2 teeth; body and base of the palp are haired yellow, the stigma is smaller, the part below the submedian is absent. Mexico.

incantator.

A. incantator Drc. is only known in the ♀. It is allied to *aestria* and *dysoni*, but beneath distinguished by the other silvery spots. Wings basally densely haired reddish-yellow. Beneath the forewing is coppery-brown, in the proximal part blackish-brown, the proximal margin lighter; in the middle of the dark copper-brown hindwing there is an irregular silvery spot composed of quadrangular confluent spots, with 2 smaller spots, one at the cell-end and a somewhat larger one behind it above the median. Costa Rica.

115. Genus: **Paraides** G. & S.

Separated from the preceding genus only by a different shape of the scent-spot: one spot is situate on the lower median vein near its base, another spot below it and a third on the submedian; the stigma may also be absent.

ocrinus.

P. ocrinus Plötz (= *argyrina* Stgr. i. l., *callidanas* Mab.) (184 b, c) looks above almost like *Aides elara*, but the base of the hindwing is haired green; it is very closely allied to the following *aegita*, but it has a stigma of 3 small parts, whereas *aegita* has none at all. On the hindwing beneath there is a large silvery spot below the cell and 2 smaller ones behind it. From Panama to Colombia, Guiana, Amazon, Brazil.

aegita.

P. aegita Hew. (184 c). Above blackish-brown, towards the base and on the body haired olive-yellowish, with a large white cellular spot and 3 postdiscal ones behind it and below it on the forewing; the hindwing exhibits a round white postcellular spot. Beneath cherry-brown, in the disc of the forewing blackish, at the proximal margin lighter grey. Hindwing with a large trapezoid silvery spot below the cell and two smaller ones behind it, one near the margin. Brazil (Pará).

P. anchora Hew. (184 c) is above coloured and marked entirely the same, but somewhat smaller. *anchora*. Beneath the red-brown parts are lighter, the large silvery spot of the hindwing is not situate below the cell, but behind it, and near the distal margin there is only a smaller silvery spot. Likewise from Pará; Trinidad.

P. brino Cr. (184 d) resembles *anchora* above except the more ochreous-yellow hairing on the body *brino*. and the base of the wings. Beneath on the red-brown hindwing 2 transverse silvery spots, both composed of 3 spots each. From Surinam.

P. argyrostactos Mab. belongs to the same group from which it differs by the absence of the white *argyrostactos* spot on the hindwing beneath. Above deep brown, at the base ochreous-yellow; forewing with 4 white hyaline spots, a double one in the cell and 3 obliquely behind it, the middle spot being large, the lowest small, oval. Forewing beneath blackish, at the base, round the spots, at the apex and at the distal margin red-brown, dusted with yellow. Hindwing red-brown, strewn with yellow, with 3 silvery spots, 1 in the cell and 2 below it. Expanse of wings: 48 mm. Brazil.

116. Genus: **Xeniades** G. & S.

Distinguished from the two preceding genera by the straight distal margin of the forewing. The stigma is almost the same, but some species have one scent-stripe more on the median.

X. orchamus Cr. (= *licia* Plötz) (184 d) resembles *Aides epitus* (184 a, b), but the silvery spot is *orchamus*. different and forms a band from the middle of the costal margin almost to the anal angle, which is broader here; towards the apex there are 2 to 4 more smaller silvery spots; fringes white, at the forewing towards the costal margin smoky. Panama to Brazil. — f. **xanthothrix** Plötz (184 c, d) is on the body and the base of the *xanthothrix*. wings much brighter ochreous-yellow, also the hyaline spots are more yellowish, on the hindwing there are only 2; on the hindwing beneath there is only the proximal silvery spot, the distal arm broken up into very small spots. Rio de Janeiro.

X. difficilis sp. n. (184 d) does not differ from *orchamus* above. Beneath the submedian spot of the *difficilis*. forewing is much smaller, more indistinct; the principal mark is the differently shaped silvery band of the hindwing, which is broader, towards the base convex from the costal margin to in front of the proximal margin, penetrating much farther into the cell than in *orchamus*, where it is proximally almost rectilinearly defined; below the costal margin it is interrupted so that there is here an isolated spot; another difference is in the dark fringes; in *orchamus* they are white and also bend yet for some distance upwards at the proximal margin. According to 1 ♂ from Coroico (Bolivia) from the Coll. FASSL.

X. laureatus sp. nov. (184 d) is above deep dark green on the body and base of the wings, the ground- *laureatus*. colour being black, not brown; the small subapical dots are minute, also the submedian spot is very small, all the hyaline spots purely white; on the hindwing there are 4 postdiscal spots, 2 of which are always situated together. Beneath somewhat duller, more brownish; above the cellular spot the costal margin is spotted white, the submedian spot is enlarged to half of the submedian area and opaque white. On the hindwing there is near the distal margin a white, smoked band in which the hyaline spots are situate at the proximal margin. Body, palpi below and base of club white like the fringes. According to 1 ♂ from the Songo (Bolivia) from the Coll. FASSL.

X. pteras G. & S. (184 e) is very much like the following *chalestra*, but the hindwing above is without *pteras*. the proximal spot, and the body and base of the wings is more intensely metallic green. Beneath chestnut-red, hindwing with a straight, creamy-white band turning upwards at the anal angle. Panama, Colombia, Venezuela, Trinidad.

X. chalestra Hew. (184 e). Brown, on the forewing with a cellular spot and 3 large postdiscal ones, *chalestra*. all of which are whitish-yellow hyaline, the two upper ones distally concave, and with 3 small subapical stripes. Hindwing with a round cellular spot and 3 behind it. Beneath the hindwing is chestnut-brown with a broad, creamy-white band being towards the anal part bent round in an acute angle, and the 3 postdiscal spots from above behind it. Colombia, Brazil. — In f. **concors** H.-Schäff. the white dots behind the band of the hindwing *concors*. beneath are absent.

X. cecropterus nov. sp. (184 e) is somewhat smaller, the hindwing rounder, instead of the scent- *cecropterus*. spots there are long hair. Above as the preceding, but the spots of the forewings are somewhat differently shaped, the hindwing not spotted. Thoracal hairing greenish bluish-grey. Beneath the forewing is apically tinted red-brown, the cellular spot is towards the costal margin continued in a yolk-coloured spot, the lowest fades away in the lighter anal angle. Hindwing deep blackish-brown with a somewhat reddish tint; the upper half of the distal margin and the costal angle are broadly creamy, ending pointed downwards. 2 ♂♂ from the Coll. FASSL from the Rio Songo (Bolivia).

117. Genus: **Telles** G. & S.

Very closely allied to the preceding genera. Antennae half as long as the costal margin; forewing less prolonged, but hindwing at the anal angle. The ♂ is without the scent-organ; middle tibiae with spurs.

T. arcalaus Cr. (184 e). Blackish-brown, base of wings and body metallic green; forewing with 2 *arcalaus*. cellular spots and 3 below and behind them, the second being very large, triangular, before the apex there are 3 very small spots and 2 smaller ones below them, all yellowish hyaline. The hindwing shows towards the apex

3 spots in an oblique row and 2 subcostal ones. Under surface more reddish, forewing at the anal angle lighter, the costal margin and apex chestnut-red and marked yellow like the hindwing which is grey in the cell, at its end white; behind the cell-end 4 yellow spots. Panama, Guiana, Amazon.

118. Genus: **Thespius** G. & S.

Antennae scarcely half as long as the costal margin; forewing at the apex somewhat tapering, the distal margin somewhat concave, the cell as long as two thirds of the costal margin; the middle radial very much bent nearing the base of the lower radial; hindwing as long as the abdomen; body strong; the ♂ exhibits a scent-stripe from the rise of the upper median vein obliquely to the middle of the submedian, being mostly interrupted. As to the synonymy there prevails an incredible confusion.

othna. **Th. othna** Btlr. (= *macareus* Plötz) (184f, g). Above blackish-brown, towards the base and on the body haired ochreous with a cellular spot on the forewing, and 3 postdiscal small spots, the middle of which is the largest, quadrangular, and 3 subapical ones. Hindwing towards the apex with 4 postdiscal spots situate in one row, all of them slightly yellowish. Beneath lighter, apex of forewing, and the hindwing marbled red-brown and yellowish, and particularly behind the hyaline spots there appears a narrow red-brown spot; in the basal area also lilac-grey dusting. Mexico; Brazil. It is not impossible that this is *macareus* H.-Schäff.; the species *macareus* in one of the following paragraphs would in that case have to be denominated *emacareus*.

argentina. **Th. argentina** sp. nov. (184g) strikingly resembles *othna*. The hyaline spots of the forewing above are on an average larger, especially the spot between the median veins; the hyaline band of the hindwing is situate more closely to the distal margin, being broader and shorter and ending towards the apex broadly quadrangular, not in a pointed end as in *othna*; hairing of the body and of the base of the wings is slightly more olive, not so ochreous-yellow. Beneath the forewing is almost the same, the white stripe parting the apex is just a little more distinct; on the hindwing the different position of the hyaline spot is much more conspicuous than above, it is situate much closer at the distal margin and extends with its lower end towards the anal angle, whereas in *othna* it is turned more towards the middle of the proximal margin; above its upper end another silvery white hyaline stripe extends towards the middle of the costal margin and is proximally broadly bordered with ferruginous yellow; in *othna* it is only occasionally traceable at the costal margin in a quite different direction, running obliquely proximad. The median and the upper radial are white. From Argentina (Salta).

bogotana. **Th. bogotana** sp. n. (184f) is another similar form. Above like *othna*, but the hyaline spot of the hindwing does not end towards the apex in a pointed end, but is quadrangular as in *argentina*, but it is far remote from the distal margin; in the cell-end there is a yellowish-white punctiform spot. Beneath the hindwing is without any ferruginous tints, the costal margin and the middle of the distal margin are broad whitish, densely strewn with a deep cherry-brown colour; the hyaline spot is distally bordered by a narrow blackish-red line parted by the white veins; towards the proximal margin from the hyaline spot there is a dark blackish-brown triangular spot towards the base and distally bordered with white, towards the apex a narrow similar stripe turned towards the base and proximally bordered with white. Colombia (Bogotá).

aspernatus. **Th. aspernatus** sp. nov. (184f) by the bluish-grey hairing of the body and of the base of the wing forms the transition to *macareus*. Above otherwise hardly different from the others; the hyaline spot of the hindwing consists of 4 equally large longitudinal spots and extends from the apex almost in front of the middle of the proximal margin. Beneath the apex of the forewing is not parted by white, but above and below equally broad greyish-white, scantily strewn with deep cerise. The same is the hindwing in the whole apical half, from the middle of the costal margin almost to the anal angle, otherwise dark cerise, the darkest in the shape of irregular spots in the disc, the largest of which borders proximally on the hyaline spot; distally only the lowest hyaline spot is bordered with dark. From Paraguay.

macareus. **Th. macareus** H.-Schäff. (= *emacareus* Plötz) (184f) is marked above exactly like *othna*, but the spots are whiter, and the hairing of the body and the base of the wing is dull greenish bluish-grey, not ochreous. Beneath also marked almost the same, less yellow with 1 or 2 distinct dark dots at the costal margin of the hindwing. Mexico to Venezuela.

marsa. **Th. marsa** Mab. from the Rio Grande is likewise similar to *othna*. Blackish-brown, base of forewing and costal margin as far as the 3 apical spots reddish-yellow; in the cell a double spot, behind it in an oblique line 5, all yellowish-white, the uppermost punctiform, the lowest dark yellow. Hindwing with 2 groups of white hyaline spots: 2 larger ones between the radial veins, 2 smaller ones above them; at the base a reddish-yellow dot. Forewing beneath red-brown, proximal margin blackish; from the apex to the upper median vein extends a ferruginous band. Hindwing purple-brown, spots as above, but silvery white, the first group in a yellow band, distally to it towards the apex a white band; margin ochreous-yellow, basal dots white. Expanse of wings: 36 mm.

lutetia. **Th. lutetia** Hew. (184f) (transition to the *xarippe*-group). Above like *macareus* and just as bluish-green on the body and base of the wings; the spots smaller, 5 postdiscal ones (punctiform); the hyaline band of the hindwing narrow. Beneath purple brown or cerise; apex of forewing parted by a white long stripe which appears distally dentate white on the veins. The hindwing is only at the apex very little strewn with white; the hyaline spot is retort-shaped, its white point terminating into the apex; below it and somewhat

towards the margin there is a white crescentiform spot; costal margin basally white; through the middle of the cell extends a white stripe, the interrupted prolongation of which in a distal direction is formed by the white retort-beak and which sends a white band upward before the cell-end to the middle of the costal margin, in which band an oval spot of the ground-colour is enclosed; the basal lower half of the cell and the space towards the proximal margin is white strewn with cerise. Brazil (Rio de Janeiro).

Th. vividus *Mab.* is above blackish-brown with a cell-spot, 5 postdiscal dots in an oblique line and 3 subapical dots. Fringes whitish speckled with black. Hindwing in the middle with a light yellow hyaline spot composed of 2 large and 2 smaller ones. Forewing beneath blackish, at the apex reddish with a yellowish-white, small oblique band. Hindwing brown, the 4 spots blurred, situate in a yellowish-white band extending from the costal margin to the proximal margin and being connected below the cell with a parallel basal band; veins striped white, proximal margin blackish. Expanse of wings: 30 mm. Brazil. *vividus.*

Th. xarippe *Btlr.* (185 a) is a large, beautiful species, spotted above as the others, on the forewing below the subapical spots two more spots farther distally; apex parted by light; hindwing with a quadripartite angular spot. Beneath very characteristic: chestnut-brown, apex of forewing parted by white, hindwing with a narrow subbasal transverse band and an angular postdiscal band one side of which extends to the distal margin, anastomosing at the other end with the basal band. Brazil. *xarippe.*

Th. hieroglyphica *sp. nov.* (184 g) is not dissimilar on the whole, somewhat smaller, above very similar. The cell-spot is very small, the submedian spot more intensely yellowish; on the hindwing no angular band, but a straight one extending pointed to the apex, before it in the middle of the cell a small light spot. Fringes on both wings analwards lighter, on the hindwing also at the costal angle. Beneath very variegated and with peculiar markings, arranged as in *xarippe*; the light stripe parting the apex of the forewing is much steeper, almost parallel to the distal margin; on the hindwing the proximal transverse band is broken up into 2 almost longitudinal ones, the dark ground of the wing is in the costal half white strewn with cherry-brown, the veins before the middle of the distal margin white, the distal band of the hindwing terminates into the apex. Described according to 1 ♂ from the Rio Songo (Bolivia) in Coll. FASSL. *hieroglyphica.*

Th. opigena *Hew.* (184 g). Above dark brown. Forewing with a transparent cell-spot, 4 spots in an oblique line behind it and 3 subapical ones. Hindwing with a transverse band of 4 spots. Beneath as above, hindwing crossed by 2 broad grey antemedian and distal-marginal bands. South America (?). *opigena.*

Th. ovinia *Hew.* (184 g) resembles the preceding above, but the band of the hindwing is composed of 3 small, separate spots approaching the distal margin and parallel to it. Hindwing beneath browner than in the following, the spots larger and more than coherent narrow bands. Nicaragua. *ovinia.*

Th. zaovinia *Dyar* (= *rupilius* *Schs.* ♀) (184 h) has a broader and rounder shape of the wings, dark brown, above marked as the preceding; the median of the subapical spots is removed proximally. Fringes on the ends of the veins somewhat speckled. Beneath little lighter, behind the middle of the proximal margin of the forewing a large white spot. Hindwing strewn with lilac-grey, with 4 postdiscal white punctiform spots, 2 at the costal margin and 1 or 2 in the cell. Mexico, Costa Rica. *zaovinia.*

Th. gayra *Dyar* is above brownish-black, the spots dark yellowish-hyaline, very large, as numerous and arranged as in *zaovinia*, the hindwing besides with a faded cell-spot; fringes light yellow. Beneath the same, hindwing tinted purple, with the hyaline spots as above and 2 brown transverse bands in and behind the middle. Expanse of wings: 40 mm. Mexico (Guerrero). *gayra.*

Th. himella *Hew.* (184 h). Above spotted and coloured as *lutetia*, but the fringes are more intensely speckled white and black. Beneath easily recognizable by the extensive white basal and discal areas of the hindwing with small black spots; proximal margin irregularly black, distal margin red-brown; also on the forewing a subapical, red-brown spot. Brazil (Rio de Janeiro). *himella.*

Th. cicus *Mab.* Deep blackish-brown, base haired ferruginous with 8 yellowish-white hyaline spots, a small one in the cell, 3 subapical ones and 4 postdiscal ones in an oblique line; stigma whitish, in the middle interrupted. Hindwing towards the apex with 3 transparent dots. Forewing beneath purple-brown, at the distal margin lilac. Hindwing purple-brown, at the distal margin and round the 3 discal spots strewn with lilac; proximal margin deep brown, fringes white. Expanse of wings: 46 mm. Brazil. *cicus.*

Th. superior *sp. nov.* (184 h) is above blackish-brown, marked as *cicus*, but towards the base and on the body with decidedly ferruginous hair; hindwing with a broad hyaline band of 4 spots. Fringes bright orange-ochreous. Beneath deep red-brown, apex of forewing and upper distal-marginal half strewn with lilac-grey. Hindwing in the basal third and before the middle of the distal margin strewn with lilac-grey, so that the hyaline spots are broadly surrounded by red-brown; also the base itself is red-brown. This large, beautiful species is found in Bolivia. *superior.*

Th. cacajo *Dyar* (185 a) is allied to *dalmani* and *macareus*. Above bronze-black, towards the base ochreous-yellowish; the spots yellowish-hyaline, arranged as in the said species, the cell-spot quadrangular, in the middle strangulated; only 3 postdiscal spots, that in the middle being the largest, the two upper ones quadrangular; hindwing with 3 postdiscal spots, separated by the veins, growing smaller towards the apex. Beneath as above, forewing behind the apical spots with a ferruginous nebulous stripe, behind it a purple line. *cacajo.*

Hindwing in the disc dusted with purple; below the hyaline spots a large, triangular, brown spot narrowly bordered with purple; behind the hyaline spots 3 ferruginous spots separated by the veins. Expanse of wings: 36 to 40 mm. Mexico (Guerrero, Cuernavaca).

dissultus. **Th. dissultus** *sp. nov.* (185 a) is a smaller species, above intensely reddish-yellow, the spots yellowish, the submedian spot quite ochreous-yellow, the cell-spot very small, only 3 postdiscal spots; hindwing with 4 narrow, light ochreous, small spots. the two middle ones transparent and more white. Beneath duller brown without any red or reddish-yellow tints, apex of forewing parted by white, before it with a deep brown triangular spot proximally bordered with white and exhibiting a white dot at the costal margin. Below the base of the costal margin of the hindwing a white stripe and through the middle of the cell above the radial veins as far as the apex a white stripe from the middle of which a branch extends to the middle of the costal margin, in the middle of which a small brown streak-spot is situate. Below the cell 2 large, blackish-brown spots on each side bordered with whitish, the proximal one being smaller; the two postdiscal hyaline spots are likewise distally bordered by dark brown spots; proximal margin dark brown. South Brazil.

dalmani. **Th. dalmani** *Latr.* (185 a) is twice as large, otherwise very similar; the hyaline spots are larger, on the forewing without the yellowish tint; bases of wings not so reddish-yellow, more olive-yellowish. Beneath very much like *dissultus*; the white longitudinal stripe through the cell of the hindwing and its costal-marginal branch are absent, the cell and the apical costal-marginal half are monotonously pinkish-grey or whitish; the blackish-brown spots below and behind the cell are very prominent, the spot situate towards the base below the cell being very small. Fringes at the anal angle ochreous-yellowish. Mexico to Colombia, South Peru.

guerreronis. — In f. **guerreronis** *Dyar* (185 a) from West Mexico the blackish-brown spot of the hindwing beneath is much larger and triangular and reaches beneath to the lower end of the white hyaline spot.

119. Genus: **Vacerra** *G. & S.*

As *Thespies*, but on the forewing the lower median vein rises much nearer at the base, and the stigma consists of two narrow, scarcely visible longitudinal stripes, a short one below the lower median vein and a longer one above the base of the submedian.

bonfilsii. **V. bonfilsii** *Latr.* (Mab. Gener. Ins. 17 d, p. 148) has unfortunately remained unknown to us.

litana. **V. litana** *Hew.* (= caprotina *H.-Schäff.*, socles *Plötz*, aeos *Plötz*, cabenta *Plötz*) (185 b) looks above like *Thespies macareus* (184 f), body and bases of wings with dull ochreous hair, easily discernible by the entirely different, indistinct stigma. Hindwing beneath at the base cerise, distally more lilac-grey with a yellowish-white band and cell-spot. From Mexico to the Amazon.

egla. **V. egla** *Hew.* (185 b) is similar, smaller, the cell-spot on the forewing divided into two, all the spots narrower, the band of the hindwing longer, all the spots in it equally broad. Beneath lighter, hindwing more mixed with cerise, with a bone-coloured white band. Mexico, Nicaragua, Panama.

lachares. **V. lachares** *G. & S.* (185 b) is very similar, but larger, below the subapical spots of the forewing two more spots, the band of the hindwing is more pointed towards the proximal margin. Beneath much darker than *egla*. From Costa Rica.

caniola. **V. caniola** *H.-Schäff.* (= canente *Btlr.*) (185 c). Above as *litana*, beneath the hindwing exhibits a straight white band from the apex to the anal lobe, not so far as the angle. In the ♂ the cell-spot is divided into two. Costa Rica.

dalima. **V. dalima** *Plötz* (185 d). Blackish-brown, on the forewing with 3 postdiscal spots, 2 subapical ones and one minute cell-spot, on the hindwing with a narrow, white postcellular transverse band of 4 small spots. Beneath as above, but very much duller brown, in the disc of the forewing black. Brazil.

120. Genus: **Tirynthia** *G. & S.*

Differs from *Vacerra* by a longer antennal club; the costal margin of the forewing is bent convex at the base, the cell is shorter than $\frac{2}{3}$ of the costa; the middle tibiae without spines and the ♂ is without the scent-scale apparatus.

conflua. **T. conflua** *H.-Schäff.* (185 c) resembles *Vacerra egla* above, but it has no cell-spot. The hindwing shows a short, ochreous-yellowish postcellular band divided by the veins. The hindwing beneath is light brown with a broad, straight white band from the apex to the darker middle of the proximal margin which it does not reach. Nicaragua to Paraná.

cinica. **T. cinica** *Plötz* (185 b, c) differs from *conflua* by smaller white spots increased by a cell-spot; the hindwing only shows a roundish discal spot. Beneath scarcely different from *conflua*, but in the middle of the costal margin is a yellow spot, and the inner-marginal area is broadly greyish-white. From Pará.

osca. **T. osca** *Plötz* (185 c) is doubtfully placed here. Above blackish-brown, with a basal green reflection; forewing with a large, quadrangular cell-spot and 2 behind it, as well as 3 subapical dots. Hindwing with 2

white, small punctiform spots behind the cell and yellowish fringes. Beneath lighter brownish-grey, apex of forewing with a whitish-spot, and with a submedian lighter part at the proximal angle; the hindwing besides shows a whitish cell-dot. From Venezuela (Caracas).

T. xanthosticta Plötz (185 d) is very similar; above without the green reflection, instead of which the costal margin is red-brown. Forewing only with a subapical dot, hindwing only with a whitish postcellular spot. Beneath without the white apical spot and anal-angular spot. Pará. *xanthosticta*.

121. Genus: **Niconiades** Hbn.

Antennae with clubs long, slender; palpi erect with a short terminal joint. Distinguished by the prolonged hindwings. ♂ stigma tripartite: a triangular piece in the angle where the lower median vein starts from, a long stripe below it and a shorter one on the submedian.

N. xanthaphes Hbn. (185 d). Above blackish-brown, bases of wings and body with metallic green hair, stigma grey; spots white hyaline: a bipartite cell-spot, 3 postdiscal dots and 2 or 3 subapical dots. Hindwing with a postcellular double spot. Beneath lighter, in the basal half of the costal margin ochreous-yellow with a narrow, irregular band from the costal margin to the anal angle. Mexico to Brazil. *xanthaphes*.

N. caeso Mab. (185 d) is very similar, but immediately discernible by 3 spots of the hindwing. Mexico to Brazil and Trinidad. *caeso*.

N. merenda Mab. (185 d, e) is above likewise similar, but smaller, the subapical dots almost extinct. Hindwing beneath without a band, only with a small cellular dot. From Panama, Venezuela to Brazil. *merenda*.

N. merendula Schs. resembles the preceding. Head and thorax greenish; wings brown with darker fringes; forewing with 3 small, subapical spots, a large cell-spot being strangulated in the middle, a large, quadrangular spot below it and a smaller one behind the lower cell-angle, all white hyaline, and a yellow submedian patch. Hindwing with a small, round, yellow cell-spot and 4 small, whitish antemarginal spots. Beneath lighter brown, forewing basally darkened, the submedian spot larger and white. Hindwing as above. Expanse of wings: 31 mm. Castro, Paraná. *merendula*.

N. viridiceps Mab. (185 e) resembles *merendula*, but it is larger, the subapical dots are larger. Hindwing above with a short, white band, beneath except the cell-dot with 2 small spots near the costal margin and 3 near the anal angle. Panama. *viridiceps*.

N. cydia Hew. is very much like *Oxyntes corusca* (185 e); it is larger, hindwing at the anal angle more prolonged; besides the ♂ has the stigma described above, on the submedian a longitudinal, not transverse scent-stripe. From Brazil. — f. **besekei** Plötz (185 e) has on the hindwing beneath a broader white band. Novo Friburgo. *cydia*, *besekei*.

N. antus Mab. is above black; the forewing exhibits a white hyaline quadrangular cell-spot; a longer one below it is connected with it, a smaller one is situate distally above it; below the apex 3 hyaline dots. Hindwing with 2 small postcellular hyaline spots. Beneath red-brown, distally more brightly coloured with the spots of above and a whitish patch at the anal angle of the forewing. Expanse of wings: 42 mm. Brazil (Sa. Catharina). *antus*.

N. andricus Mab. We had no access to a description of this species. *andricus*.

N. sabaea Plötz (185 f). Blackish-brown, thorax and bases of wings with a green reflection, on the forewing with a large, strangulated cell-spot, 2 behind it and a small, yellowish submedian patch and 2 subapical dots. Hindwing with 2 or 3 postcellular dots and lighter fringes. Beneath lighter brownish-grey, in the lower half of the forewing black, the discal spots confluent and united with a large, white submedian spot. Brazil, Colombia, from the latter country with smaller hyaline spots. *sabaea*.

122. Genus: **Oxyntes** G. & S.

On the forewing the middle radial vein is still nearer at the lower cell-angle than in *Niconiades*, the hindwing is scarcely prolonged at the anal angle and does not project beyond the abdomen. Instead of the lowest longitudinal scent-stripe on the submedian the ♂ exhibits a transverse stripe.

O. corusca H. Schöff. (= *martius* Mab., *cisa* Plötz) (185 e) very much resembles *Nicon. xanthaphes* (185 d), but it is distinguished by the shorter hindwing, the different stigma and unspotted hindwing. Head, body and bases of wings are green; hindwing beneath lighter, with a broad white band as in *Tir. conflua* (185 c). Mexico, Panama to Brazil. *corusca*.

123. Genus: **Phemiades** Hbn.

Antennal club thick and long with a short apex; palpal terminal joint short; apex of forewing hardly prolonged, hindwing broad and rounded; posterior tibiae with long fringes. The ♂ shows a straight, narrow scent-stripe from the lower median vein to the submedian.

propertius. **Ph. propertius** F. (= *memuca* Hew.) (185 e). Above blackish-brown, with a postdiscal band composed of 3 pale yellow spots and 4 or 5 reddish-yellow, small subapical spots; costal margin of forewing in the middle-reddish-yellow, hindwing with a reddish-yellow transverse band. Beneath very conspicuous owing to the creamy hindwing with 2 red-brown transverse bands; at the proximal margin a black wedge-shaped spot. Brazil.

jamaicensis. **Ph. jamaicensis** Schs. Above bright reddish-yellow, distal margin and a stripe from the cell to the apex blackish-brown; in the basal area a large blackish-brown spot from the subcostal vein to the lower median vein, into which from outside the reddish-yellow colour penetrates in the shape of a stripe. Hindwing with a broad, black costal margin and distal margin widened as far as the cell-end. Beneath the costal margin, apex and distal margin are reddish-brown, with a darker antemarginal shade, at the anal angle black; base black as well as a large spot at the cell-end. Hindwing dark reddish-brown, distally lighter with a yellow discal spot and a black triangle above the anal angle. Expanse of wings: 43 mm. Jamaica.

phineus. **Ph. phineus** Cr. (185 e) is a doubtful species. Above similar to *jamaicensis*, but on the forewing only with 2 reddish-yellow subapical spots, and the 2 upper spots of the postdiscal band are likewise reddish-yellow. Hindwing crossed by a broad creamy transverse band. Described from Surinam.

simulius. **Ph. simulius** Drc. (185 f) is a large, strong species with a remarkably strong anterior body and a stout head. Above dark brown, thorax and bases of wings haired green. Forewing with an ochreous-yellowish cell-spot and 3 small postdiscal ones obliquely behind it, as well as 3 subapical dots; hindwing with 3 extinct, small, ochreous-yellowish postcellular spots, fringes lighter whitish. In the ♀ the spots are larger and form on the hindwing a band beginning from the costal margin. Beneath lighter brown, the discal spots of the forewing flown together with a large, yellowish-white submedian spot into a transverse band. Hindwing with a broad silvery white band. Peru and Bolivia.

procax. **Ph. procax** sp. nov. (185 f) resembles *simulius* above, but it is somewhat smaller, the postdiscal row of spots a little more oblique, the cell-spot absent. On the hindwing the spots are situate more behind the lower cell-angle. Body and bases of wings not green, but ochreous-yellow. Beneath light brown, on the hindwing with a round, light cell-spot and a bent row of dots behind it, the largest spot being situate near the proximal margin. Bolivia.

124. Genus: **Thoon** G. & S.

Antennae somewhat longer than half the costal margin. Apex of forewing prolonged, the middle radial at its rise very much bent down. Hindwing at the anal angle prolonged, projecting beyond the abdomen. Middle tibiae with spines. Scent-scale stripe of the ♂ composed of 2 parts: a triangular part in the angle where the lower median vein proceeds, and a short longitudinal stripe above it.

modius. **Th. modius** Mab. (= *stilio* Mab.) (185 f) looks above almost like *Tirynthia conflua* (185 c), but the spots are smaller. Hindwing beneath light brown with an ochreous-yellow cell-dot and 4 in an oblique line behind it. Guatemala, Nicaragua, Costa Rica and Panama.

taxes. **Th. taxes** G. & S. (185 g) is similar, though smaller; on the forewing the subapical spots are absent, hindwing without a macular band. Beneath without the cell-spot of the hindwing. The black stigma is very distinctly prominent. From Panama.

lugens. **Th. lugens** Schs. Dark brown with lighter fringes. Forewing with a black stigma. Beneath the forewing is reddish-brown, at the proximal margin lighter. Hindwing violettish-brown except the proximal margin; a small cell-spot and some small, similar postdiscal spots as well as the proximal margin are lighter brown. Expanse of wings: 27 mm. Petropolis.

125. Genus: **Rinthon** G. & S.

Distinguished from the preceding by somewhat less prolonged hindwings and only one longitudinal scent-scale stripe on the submedian.

chiriquensis. **R. chiriquensis** Mab. (= *cabella* Plötz) (185 g). Above blackish-brown with a white-hyaline cell-spot, a very large, quadrangular spot distally below it, and a small one more towards the margin above it; 3 subapical hyaline spots the lowest of which is removed more distally; hindwing with 3 small light ochreous postcellular spots in a straight line. Beneath the same, but duller, the proximal margin of the forewing lighter; hindwing a little strewn with whitish, the small spots whitish, besides with a cell-dot. Mexico, Guatemala and Panama.

R. bomax Schs. Dark brown, on the forewing with a narrow, transverse white hyaline spot between the median veins and a very small round spot above it. Beneath dark brown, tinted violet, on the forewing the anal angle and proximal margin are lighter brown. Hindwing with a small, yellow cell-spot and a dot behind the lower cell-angle. Expanse of wings: 36 mm. Petropolis. — **zaba** Str. belongs perhaps as a form to it, it is distinguished by 2 minute subapical dots, only one more small cell-spot, the hindwing beneath being unmarked. Mexico, Argentina. *bomax.*

R. tanaris Schs. is above as the preceding, but without the narrow lower hyaline spot. Beneath the forewing has a broad lighter brown distal margin and apex and is spotted as above, but with a light transverse stripe below it. Hindwing tinted violet above the median and the lower branch. Expanse of wings: 36 mm. Brazil (Tijuca in the Organ Mountains). *tanaris.*

R. dyma Plötz (185 g) is above dark brown with 3 white subapical dots, 2 large white postdiscal spots and a yellow submedian diffuse spot in front of which the lead-coloured scent-stripe is situate on the submedian. Hindwing with a white dot behind the lower cell-angle, and with ochreous fringes. Beneath light reddish-brown, disc of forewing black, being continued towards the margin like a diffuse patch above the lower median vein. Hindwings with darker brown basal and discal bands and small triangular spots on the margin between the veins; beside 2 white postdiscal dots there is a cell-dot. Brazil. *dyma.*

R. advena sp. nov. (185 g) is smaller; the blackish-brown forewing shows 2 small, white, hyaline cell-spots, 2 postdiscal spots the lower of which is much larger than the upper, and three subapical dots. Hindwing with a hyaline dot behind the lower cell-angle. Beneath duller, the anal angle of the forewing lighter, hindwing with a white cell-dot and 2 behind the cell. Bolivia; South Brazil. *advena.*

R. luctatus Schs. is above black, on the head with a slight green reflection. The forewing exhibits 2 small greyish-white spots between the median veins and above them. Beneath duller and lighter, the spots whiter, clearer, near the anal angle a greyish-brown spot; on the hindwing 2 reddish dots behind and below the cell. Mexico. Costa Rica. *luctatus.*

R. cynea Hew. (= *crebina* Mschlr., *tersa* Mschlr., *kasus* Mschlr.) (185 h). Forewing with only 2 small white spots, one of which is subapical; hindwing unspotted. Beneath the hindwing shows a cell-dot and 3 behind it, the anal angle of the forewing is broad, white; head and thorax with a green reflection. From Mexico to Colombia and Venezuela. *cynea.*

R. bistrigula H.-Schüff. (= *alus* Mab., *vellius* Plötz) (185 h) is above very similar; beneath the forewing does not show a white anal angle, and the hindwing is entirely uni-coloured blackish-brown, like the head and thorax. From Panama to Guiana, the Amazon and Bolivia. *bistrigula.*

R. melius Hbn. (= *irma* Mschlr.) (185 h) is above quite blackish-brown with a long, lighter stigma; forewing towards the proximal margin and hindwing on the anal fold long-haired. Beneath the wings are tinted purple, forewing at the anal angle lighter, at the apex and distal margin grey. Of the same colour are the distal and proximal margins of the hindwings. Mexico to Colombia, Brazil, and in Trinidad. *melius.*

R. anthracinus Mab. (= *epaphus* G. & S.) (185 h) is much larger than *melius*, above the same; well discernible on the hindwing beneath by the distal margin being broadly coloured ochreous-yellow analwards. Guatemala to Brit. Guiana. *anthracinus.*

R. megalops G. & S. (185 h). Above uni-coloured blackish-brown; beneath hindwing as in *cynea*, but the forewing without a white anal angle; head and eyes remarkably large, frons and prothorax with lustrous green hair. Mexico, Costa Rica and Panama. *megalops.*

126. Genus: **Cobalus** G. & S.

Antennal club with a long, turned-round apex; palpi erect; hindwing at the costal angle somewhat prolonged, analwards somewhat convex. The ♂ is without the scent-scale stripe.

C. fidicula Hew. (= *hesiodus* Plötz) (185 i). Forewing with 3, sometimes 4 white spots, 1 or 2 of which are subapical, the lowest spot being the largest. On the hindwing before the middle of the distal margin an oval white spot. Beneath more reddish, otherwise as above, but the proximal margin of the forewing shows a fifth white spot. Honduras, Costa Rica, Panama. *fidicula.*

C. virbius Cr. (= *hersilia* Plötz) (185 i) is very closely allied to *fidicula*, with broader and shorter wings, the white spot of the hindwing extending to the distal margin. Brazil (Rio de Janeiro). *virbius.*

C. gabina G. & S. (185 i) differs from the preceding by a white cell-spot, and the hindwing being quite unspotted. Beneath somewhat lighter. Mexico. *gabina.*

C. trimaculata Plötz (185 h) has above close together a double cell-spot and below it a large white spot, a small one being behind it. Beneath the same, little lighter, with a large, yellowish-white submedian spot of the forewing. From Brazil. *trimaculata.*

C. bryanti Weeks is doubtfully placed here. Above dark brown, basal half of costal margin strewn with golden yellow; forewing with 2 white subapical dots; 3 white postdiscal spots, the lowest being the largest. *bryanti.*

Through the middle of the dark brown hindwing extends an indistinct darker line. Beneath both wings are uni-coloured dark brown. Expanse of wings: 28 mm. Venezuela (Suapure).

- gabinus*. **C. gabinus** Plötz (185 i) is above uni-coloured blackish-brown, beneath the same, on the hindwing with 3 or 4 white, roundish postdiscal spots situate close together, only separated by the veins, the second from above being the largest and projecting towards the base; occasionally there is another dot in the disc. Brazil (Santos, Rio, Sa. Catharina).
- herminieri*. **C. herminieri** Latr. (186 a) is above blackish-brown, beneath a little lighter brown, on the hindwing more reddish, with 2 grey, small, postdiscal diffuse spots behind the lower cell-end; veins somewhat darker. Venezuela, reported from Carolina.
- nigrans*. **C. nigrans** Schs. Wings blackish-brown, beneath duller, Forewing beneath with 2 small greyish-white spots between and above the median veins, anal angle lighter brownish-grey; hindwing with an orange dot at the cell-end and 2 similar ones behind and above the cell. Costa Rica.
- laureolus*. **C. laureolus** Schs. Above blackish-brown, above on the forewing in the middle the veins darkened, hindwing in the basal half darker. Beneath lighter brown, only in the basal third of the forewing and a subapical triangular spot dark, before the latter with 3 grey dots, anal angle lighter. On the hindwing the base, a postdiscal band and large marginal spots are darker brown. Costa Rica.
- lateranus*. **C. lateranus** Schs. The blackish-brown forewing shows transparent, white spots: a large one at the cell-end, a large one below it between the median veins, and a smaller one above it more distally, a small one below it and 3 small subapical ones. Beneath the forewing is at the apex, costal and distal margins and the hindwing olive-brown, the latter with a white cell-spot and another one below the lower cell-angle. Looks above like *gabina* (185 i). Costa Rica.
- pindar*. **C. pindar** Schs. Smaller than the preceding, the spots brownish, without the cell-spot of the forewing; hindwing with a yellow hyaline dot below the lower cell-angle. Beneath lighter brown, costal margin and cell of forewing more yellowish-brown, the spots as above, anal angle lighter. Hindwing brown, transverse vein and 5 postdiscal spots darker brown, that below the lower cell-angle pupilled with the hyaline dot. Costa Rica.
- eteocla*. **C. eteocla** Plötz (= *ulrica* Plötz?) (186 b). Above blackish-brown, with a small, white cellular and submedian dot, larger postdiscal spots and 2 subapical dots. Beneath lighter violettish-brown, with blackish veins, in the anal part of the forewing lighter, with a red-brown inner-marginal part of the hindwing. From Rio de Janeiro.
- argus*. **C. argus** Mschlr. (= *yva* Plötz) (186 a) resembles the preceding above, but the subapical spots of the forewing are absent. Beneath grey, hindwing with a black cell-spot and 4 behind it in an irregular row, all of them ringed lighter. Panama to Colombia and Argentina.
- chinoba*. **C. chinoba** Weeks is above uni-coloured dark brown, towards the margin somewhat lighter with darker, small, indistinct spots in the internerval spaces near the distal margin, on the hindwing a little more distinct. Beneath brownish-drab, on the hindwing striated somewhat darker; an indistinct, darker transverse band extends from the apex to the middle of the proximal margin, another one along the distal margin; the black marginal spots are much more distinct than above; inner-marginal area light grey. Expanse of wings: 27 mm. Venezuela (Suapure).
- percosius*. **C. percosius** G. & S. (186 a) looks above like *argus*, but the forewing is without the cell-spot, but there are 3 small, subapical spots. Hindwing often with 2 small light postcellular spots. Beneath on the hindwing at the cell-end a yellow dot and 2 near the distal margin. Forewing at the anal angle lighter, yellowish-grey. Mexico, Guatemala and Panama.
- quadrum*. **C. quadrum** Mab. is above smoky black, forewing with a small subapical dot and 2 white postdiscal spots. Beneath lighter, the spots light yellow, the proximal margin of the forewing whitish, in the submedian space more ashy-grey. Hindwing black with a large, quadrangular white spot between the upper radial vein, and the inner-marginal fold, touching the distal margin. Palpi red, laterally black. Expanse of wings: 34 mm. Rio San Juan (Colombia).
- paculla*. **C. paculla** Mab. is somewhat smaller, above the subapical dot another one being hardly visible; the postdiscal spots are small, quadrangular. Hindwing here also above with a white marginal band-spot from the middle radial vein to the proximal margin; fringes above it spotted white. Beneath similar, the inner-marginal area whitish. Expanse of wings: 32 mm. Villa Bella (Brazil).
- physcella*. **C. physcella** Hew. (186 a). Above blackish-brown with a greenish reflection, 4 postdiscal white spots in an oblique row and 3 subapical dots; on the hindwing with white fringes there are 3 subapical white dots. Beneath the hindwing exhibits a broad, white distal-marginal part with a series of brownish, small dust-spots in the middle, parallel to the distal margin. Brazil.
- elegantula*. **C. elegantula** H.-Schöff. (186 b) entirely resembles above the following *quadrangula*, but it has lighter yellowish fringes. On the under surface the basal half of the costal margin and the apex of the forewing are light violet like the hindwing with a rather broad, brown, undulate marginal line. The hindwing shows right

across the middle a broad, brown transverse band distally accompanied by a fine undulate line; basally another brown spot, the inner-marginal part broad and brown. Brazil.

C. lysiteles *Mab.* is only doubtfully placed here. Jet-black, with white-hyaline spots: 3 subapical ones, 2 long ones in the cell and 4 in an oblique line behind them. Hindwing with a large oval spot with a dentate distal margin in the middle, on the teeth dusted light blue, and with a bluish-white longitudinal ray on the inner-marginal fold. Forewing beneath black with a grey proximal margin; hindwing purple black, the white spot larger, extending from the subcostal to the inner-marginal fold. Expanse of wings: 38 mm. Saragura. *lysiteles.*

C. zeppa *Plötz* (186 b) is above deep blackish-brown, with 2 white subapical dots and 2 postdiscal white spots, the lower of which is larger, reniform. Beneath the forewing is at the distal margin and in the anal submedian space light brownish-grey. Hindwing as dark as above, unmarked with light grey fringes. Surinam. *zeppa.*

C. aethra *Plötz* (186 a) is similar, somewhat larger, much lighter brown, the white spots much smaller, subapically only a dot. Beneath as above, scarcely lighter, only the disc of the forewing somewhat darker. Abdomen beneath whitish. Surinam. *aethra.*

C. quadrangula *Plötz* (= *cubana* *H.-Schäff.*) (186 b, c). Blackish-brown with an uncommonly large, quadrangular, white spot below the lower cell-end and a smaller one distally above it, as well as 3 subapical dots. Beneath in the disc of the forewing black, otherwise reddish-brownish or lilac-brownish with a light, yellowish cell-dot and a bent postdiscal row of dots. Brazil and Cuba. *quadrangula.*

C. subcordata *H.-Schäff.* (186 b) is very similar, larger, body and bases of wings faintly greenish, the white spots much smaller with whitish fringes on the hindwings. Beneath as the preceding, but the hindwing unspotted with a deep chestnut disc and lighter brown distal and proximal margins. Brazil (Rio de Janeiro). — The form **olympia** *Plötz* (186 c) is distinguished by one more postdiscal spot and has a small white dot on the hindwing beneath. Fringes tinted more ochreous. Likewise from Brazil. *subcordata.* *olympia.*

C. neroides *H.-Schäff.* (186 c), without its habitat being known, is only doubtfully placed here and greatly resembles *olympia*, but it has one more narrow cellular and submedian spot, the latter yellowish. Beneath more olive-brownish or greenish with a large, whitish anal spot of the forewing and 2 to 4 whitish postdiscal dots on the hindwing. *neroides.*

C. tertianus *H.-Schäff.* (= *warra* *Mschlr.* ♂, *zola* *Mschlr.* ♀) (186 c) is above quite uni-coloured brownish-black, in the ♀ with 2 or 3 postdiscal hyaline spots, beneath lighter; on the forewing behind the middle near the distal margin a dirty white transverse band, on the hindwing the larger basal half is dirty white, like the inner-marginal part. Costa Rica, Guiana. *tertianus.*

C. hilda *Plötz* (186 d) is above blackish-brown, on the hindwing with 3 small, whitish spots behind the lower cell-end. The ♀ has on the forewing 3 large ochreous-yellow postdiscal spots and 3 small apical spots, and on the hindwing in an acute angle to the 3 spots, which are here larger and ochreous-yellow, there is a third above them. Beneath very peculiarly marked: disc of forewing blackish-brown, distal margin behind the discal spots broadly light greyish-brown. Hindwing light brownish-grey, in the discal area, projecting distally in an acute angle and here bordered by whitish, darker; the whitish colour is the broadest towards the proximal margin, below it there is a large and a very small blackish-brown spot; a similar one is situated at the base of the costal margin. Brazil, Blumenau, 1 ♀ from Salta (Argentina) in the Coll. SEITZ. *hilda.*

C. nubila *Mab.* only doubtfully belongs hereto. Light brown with a ferruginous reflection, particularly towards the margin. Beneath lighter, more red; forewing with a submedian lighter, yellowish part, from the base to the middle blackish; hindwing still lighter and more monotonous. Expanse of wings: 36 mm. Porto Cabello. *nubila.*

C. astur *Mab.* Light brown with 2 white subapical dots and 2 spots behind the lower cell-angle, the upper being larger and quadrangular. Hindwing darker, fringes ferruginous brown. Beneath blackish, in the middle of the forewing more grey, only the upper discal spot being visible. Hindwing black with 4 white post-cellular dots, the 2 lower ones being larger. Expanse of wings: 31 mm. Coary. *astur.*

C. cleochares *Mab.* Deep blackish-brown, on the forewing with 2 small white subapical dots and 2 spots behind the lower cell-angle; fringes whitish-grey. Hindwing unspotted with lighter fringes. Beneath on the forewing the spots are more distinct, the distal half is lighter; base of hindwing blacker; a postcellular semicircle of 4 white dots, a fifth in the cell. Expanse of wings: 29 mm. Valera. *cleochares.*

C. oblinita *Mab.* is above dark brown with a light red-brown reflection and orange-brown, scarcely visible spots: 2 subapical ones and 3 postdiscal ones. Hindwing behind the middle lighter, fringes light ferruginous. On the forewing beneath the costal margin and apex are red-brown, the proximal part black with more distinct spots than above. Hindwing brown with a light red-brown band in the middle. The ♀ being placed hereto is larger and has white spots, it may belong to another species. Expanse of wings: 30 to 34 mm. Brazil (Rio Grande). *oblinita.*

C. cannae *H.-Schäff.* (= *osembo* *Mschlr.*, *byzas* *Mab.* i. l.) (186 c, d) resembles *Rinthon bistrigula* *cannae.* above, but it is well discernible by the absence of the stigma; the hyaline spots above are very variable in extent

and may be obliterated. Beneath the forewing is narrowly yellowish at the costal margin and apex, below the apex at the distal margin tinted somewhat lilac, hindwing in the proximal half brownish-yellow, at the distal margin narrowly strewn with lilac, with an indistinct, lighter, straight band from the apex to the middle of the proximal margin, and 2 light spots in the costal half. Mexico to Argentina.

fortis. **C. fortis** Schs. Dark brown, ends of fringes whitish; forewing at the proximal margin haired greenish, spots yellowish-white hyaline, one in the cell, strangulated in the middle, 2 postdiscal ones, the lower of which is the largest, and 3 small subapical ones. Hindwing in and below the cell haired greenish, with 2 small transparent spots above the median veins. Beneath brown, costal margin and apex of forewing, and hindwings strewn with greenish-yellow, base of forewing darker; spots as above, above the submedian another large whitish spot. Expanse of wings: 39 mm. Castro (Paraná).

psyllus. **C. psyllus** is doubtfully placed here. Above black with large, white spots, a large one in the middle of the cell and two between the median veins, the upper one of which is small; base light grey. Hindwing without spots, in the disc dirty yellow, fringes dark grey, speckled with black. Forewing beneath at the apex, distal and proximal margins pearl-coloured grey, hindwing dark grey with a semicircular row of 5 or 6 whitish spots. Bolivia.

derisor. **C. derisor** Mab. Deep brown. Forewing with light yellow spots: 2 subapical ones, the lower of which is larger, 2 strigiform, parallel ones in the cell, and 3 behind them in an oblique row, the lowest of which is the smallest and of a deeper yellow. Hindwing with 2 dots showing through from beneath behind the upper cell-end. Forewing beneath with a darker base, at the costal margin and apex reddish. Hindwing red-brown with a round cell-dot and the two spots mentioned above behind the upper cell-angle. Thoracal hairing of a green reflection. Expanse of wings: 36 mm. Venezuela.

hypoxanthos. **C. hypoxanthos** Mab. Black, towards the base yellowish. Forewing with a quadrangular cell-dot, 2 spots obliquely behind it, the lower one being the largest, quadrangular; 3 subapical white hyaline dots. Base of hindwing and disc brown, with fuscous hair and a black cell-spot and a curved row of black dots before the distal margin. Beneath lighter, basal part yellowish. Hindwing orange, at the distal margin blackish-brown with a curved row of minute black dots, behind them 3 more, at the base one. Abdomen orange with a white median band. Palpi white. Expanse of wings: 46 mm. Cayenne.

poecila. **C. poecila** sp. nov. (186 d). Above blackish-brown, with a ferruginous yellow cell-dot, 2 postdiscal spots and a submedian diffuse patch below them, and 2 subapical dots. Beneath very variegated, costal margin broad chestnut like the apex, the postdiscal ferruginous oblique band very much widened. Hindwing chestnut mixed with blackish, with reddish-yellow spots at the cell-end, behind it, below it near the proximal margin and at the blackish anal angle. 1 ♂ from Muzo (Colombia) taken by FASSL.

rastaca. **C. rastaca** Schs. is above similar, somewhat lighter brown, the spots smaller, particularly the cell-spot very small. Beneath still lighter brown; beside the spots of above a postdiscal row of 5 small, black spots, the middle one of which is pupilled whitish. Hindwing with a black crescentiform cell-end-streak, behind it 4 black spots, the two lower ones intensely pupilled white, the 3rd indistinctly so, the uppermost quite black. Expanse of wings: 38 mm. Petropolis.

arita. **C. arita** Schs. The dark brown forewing is without the cell-spot, with only one subapical dot. Beneath somewhat lighter, the costal margin of the forewing dusted with reddish, near the anal angle another light spot. Hindwing dusted with violet, with a small yellowish cell-dot and 5 small similar spots behind it in a bent row. Abdomen beneath whitish. Expanse of wings: 26 mm. Trinidad.

stigmula. **C. stigmula** Mab. scarcely belongs hereto. Blackish-brown, costal margin of forewing reddish-yellow; 3 postdiscal hyaline spots; the lowest very small. Forewing beneath blackish, the costal and distal margins reddish; between the apex and lower median vein with a light violet band. Hindwing from the costal margin to the middle radial vein brown, from there whitish lilac, strewn with brown; through the middle extends a row of 6 brown double dots distally spotted white; towards the apex they are smaller and more remote; in the cell a round white spot. Expanse of wings: 21 mm. Patria unknown.

cinerita. **C. cinerita** Plötz (186 d) is just as doubtful. Above blackish-brown with somewhat lighter fringes tinted ochreous, and on the forewing with 3 small postdiscal dots and 1 subapical dot. Beneath the hindwing is entirely unmarked light ashy grey; costal margin of forewing and apex somewhat lighter brown than the black disc, the submedian spot larger and ashy-grey. Brazil.

127. Genus: **Cobalopsis** G. u. S.

Scarcely separable from the preceding, only different by the strong and projecting valves of the ♂. No stigma.

pelora. **C. pelora** Plötz (= *autumna* Plötz, *edda* Mab.) (186 d) entirely resembles the preceding above, the spots are small, especially the cell-dot and 3 subapical ones. Fringes of hindwings tinted ochreous. Beneath the same, forewing with a large, light anal angular spot; the hindwing is somewhat tinted olive and shows 4 post-discal whitish punctiform spots. Mexico to Guiana.

C. dyscritus *Mab.* resembles the preceding, but the hindwing beneath is distinctly ochreous-yellow, *dyscritus*, and the genitals are different. Mexico to Peru and the Amazon.

C. rogersi *Kaye* has an intense bronze-green reflection on the head, thorax and abdomen. Forewing *rogersi*, dark blackish-brown with 3 white subapical dots; below the lower cell-angle there is a large, angular, white spot, a small one distally above it. Beneath the base of the forewing is black, the marginal area lighter; on the hindwing the disc is the darkest. Expanse of wings: 40 mm. Trinidad.

C. musa *Kaye* is somewhat smaller, above very similar, beside the spots of the preceding it has yet *musa*, 2 dots close above each other in the cell-end and another one above the middle of the proximal margin; only 2 subapical white dots. Beneath the same, with a white inner-angular spot of the forewing, and on the hindwing with a cellular spot and 6 white postdiscal spots. Expanse of wings: 35 mm. Trinidad.

C. latonia *Schs.* (189 i). Above dark brown, forewing with a fine whitish strigiform spot below the *latonia*, transverse vein, with 2 small subapical dots and a larger one behind the lower cell-angle. Hindwing with somewhat darker veins. Beneath on the forewing the costal margin, apex and distal margin are lighter yellowish-brown, the proximal margin greyish-whitish; hindwing yellowish-brown, with 5 bluish-white postdiscal spots and a blackish-brown wedge-shaped stripe near the proximal margin. Costa Rica.

C. hebon *Mab.* It is doubtful whether it belongs into this genus. Above blackish-brown with 4 hyaline *hebon*, spots, one in the cell, a small one behind it, a large, quadrangular one beneath the lower cell-angle, and a longish one below it; the base of the costal margin is red-brown, the fringes are light brown. The hindwing is proximally yellowish, behind the upper cell-angle there is a white quadrangular spot, parted by the cellular fold. The proximal margin is very concave with a broad, obtuse anal lobe. The forewing is beneath the same, at the costal margin lighter reddish, at the apex lilac, the hindwing is red-brown. Expanse of wings: 38 mm. Amazon (Massauary).

128. Genus: **Onophas** *G. & S.*

Antennae longer than half the costal margin; club as in *Cobalus*. Hindwing prolonged at the anal angle, middle tibiae spined. The ♂ exhibits a narrow, oblique scent-scale stripe from the rise of the upper median interrupted as far as below the lower median vein; above the middle of the submedian there is a transverse fold.

O. columbaria *H.-Schäff.* (— flossites *Btlr.*) (186 e) is easily discernible from all the similar species *columbaria*, by the bluish-green head, body and base of wings, and the ochreous-yellow under surface of the hindwings. Above the forewing is blackish-brown with 2 indistinct, dirty ochreous-yellow, small spots between the median veins. Distributed from Panama to Brazil, and in Trinidad.

129. Genus: **Arotis** *Mab.*

Antennae as in the preceding. Distal margin of forewing convex, the middle radial vein at its rise nearing the lower one. Middle tibiae without spines. The ♂ has a treble scent-spot: a straight stripe from the base of the upper median to the lower median vein, and in the submedian area 2 thick spots of erect scales.

A. sirene *Mab.* Above blackish-brown, distally somewhat reddish. Beneath the base of the forewing *sirene*, is blackish, in the marginal area beautifully violet. Hindwing in the basal half blackish-brown with a white cell-end dot, behind it whitish-lilac, with black veins, at the margin darkened. Brazil.

130. Genus: **Oeonus** *G. & S.*

Antennae half as long as the costal margin; the middle radial vein at its rise strongly bent downward; hindwing at the anal angle prolonged; middle tibiae spined. An oblique scent-scale stripe extends in the ♂ from below the base of the upper median vein to the lower vein near its rise, a short stripe is situate close below it, and a third in the middle of the submedian vein.

O. pyste *G. & S.* (186 e) is similar to *columbaria* above, without the intense green hue, only the *pyste*, frons somewhat greenish. It is larger, the 2 spots of the forewing are more distinct, the stigma thinner, more distinct; forewing sometimes with a minute subapical dot. Beneath lighter, the hindwing with 4 yellowish small dots near the distal margin. Mexico.

O. nausiphanes *Schs.* (189 c) is above dark brown, the costal margin of the forewing is somewhat *nausipha-* scaled yellowish, the black scent-stripe fine; fringes of hindwing yellowish-grey. Beneath the forewing is darker *nes*, in the basal halves of the cell and of the proximal margin. Hindwing dull brown with a broad, whitish discal shade, the broadest at the costal margin and not reaching to the proximal margin strewn with greyish-white. Costa Rica (Poas).

O. garima *Schs.* Dark brown, fringes greyish-brown; forewing with minute hyaline spots: a sub- *garima*, apical one, two at the cell-end, a small one behind the lower cell-end, being strangulated in the middle, a qua-

drangular one farther distally to it, only a small whitish submedian one behind the stigma. Beneath light olive-brown, forewing at the base of the costal margin blackish, the submedian spot larger. Hindwing with a small whitish spot at the cell-end, behind it in a bent row 6 minute whitish spots between the veins. Expanse of wings: 27 mm. Trinidad.

degener. **O. degener** Plötz (186 e) is above blackish-brown, on the body with a faint greenish reflection with a grey stigma, two postdiscal white spots, the lower of which is oblong and distally bordering on the stigma, and a subapical dot. Beneath scarcely lighter, in the disc of the forewing black, with 3 or 4 light postdiscal dots on the hindwing. Colombia (Pacho).

lydora. **O. lydora** Plötz (186 e) is similar, the body much robuster, the two postdiscal spots of the forewing much larger, quadrangular. The hindwing exhibits also above behind the lower cell-end a white dot. Fringes somewhat ochreous-brownish. Beneath more ochreous-brown, disc of forewing black, with a submedian large yellowish-white diffuse spot. Hindwing strewn with blackish, with 2 white postdiscal dots. Venezuela.

131. Genus: **Mucia** G. & S.

Distinguished from *Oeonus*, in which the lower median vein of the forewing rises before the middle of the cell, by this vein rising from the middle of the cell; ♂ stigma a little bent, oblique, of 3 parts: a short scent-stripe from the rise of the upper median vein to the rise of the lower one, beneath it an oblique stripe and a straight one from the middle of the submedian.

thyia. **M. thyia** G. & S. (186 e) is above like *Onophas columbaria*, but without bluish-green, the small spots smaller. Beneath the same, forewing with 4 subapical black dots. Hindwing with 3 such dots near the apex in a bent row, whereby it differs from all the similar species. Mexico to Matto Grosso.

matalma. **M. matalma** Schs. is above dark brown with a semi-transparent white spot behind the narrow black stigma, and a smaller one behind the lower cell-angle. Beneath olive-brown, forewing in the basal half dark brown, at the anal angle a somewhat lighter patch. Costal margin of the hindwing darker, near the apex a black dot and a postdiscal row of black dots, the 2 lowest being the largest. Expanse of wings: 34 mm. Petropolis.

132. Genus: **Morys** G. & S.

Discernible from the preceding genera by the hindwing being somewhat lobate at the anal angle, and the different scent-organs extending as an oblique, broad stripe from the lower median vein to the middle of the submedian.

valerius. **M. valerius** Mschlr. (= *cerdo* Bsd.?) (186 e). Above as the preceding, but with 2 subapical dots. Beneath lighter, hindwing with 4 yellowish dots in a bent row near the apex. The ♀ is tinted more purple, often with 3 white-hyaline postdiscal spots. It looks very much like *Megistias tripunctus* which, however, is without the scent-stripe. Mexico to Colombia, Venezuela and Brazil; Trinidad.

credula. **M. credula** Plötz (186 f) is much larger, but owing to the similar scent-stripe it may belong hereto. On the blackish-brown forewing there are in the cell 2 large white hyaline spots, behind them 3, and 3 subapical ones; scent-stripe silvery grey bordered with black. Beneath only somewhat lighter, more brownish. Brazil.

133. Genus: **Perimeles** S. u. G.

Separated from the preceding genera by the long-haired legs and by the scent-organ of the ♂: a bent stripe extends from the base of the upper median vein to the rise of the lower one, below it there is a short stripe and a transverse part proceeds from the middle of the submedian.

remus. **P. remus** F. (= *justinoides* Btlr.) (186 f) is a common, well-known species, easily discernible by the characteristic under surface of the hindwing: in the basal quarter deep chestnut-brown, distally bordered by whitish like the whole costal margin, in the anal three quarters gradually turning greyish-brown. Above monotonously brown. From Mexico to Brazil and Trinidad. — f. **vopiscus** H.-Schöff. from Mexico is beneath more variegated, with a more chestnut tint, on the forewing with 2 pinkish-reddish costal-marginal spots.

beda. **P. beda** Plötz (186 f) is a small species which may belong hereto. Above black with 2 minute postdiscal and 3 subapical whitish dots of the forewing, of the latter the middle dot is removed proximally. Fringes very faintly speckled lighter. Beneath the forewing is duller, more brownish, the fringes more distinctly speckled. Hindwing in the costal half with a light brownish-white broad longitudinal stripe from the base, which is sharply defined below towards the dark anal part, towards the costal margin gradually passing over into the narrow dark costal margin; in the middle of the light part there are some small dark brown spots. Brazil (Blumenau).

134. Genus: **Tigasis** G. & S.

Antennae longer than half the costal margin; otherwise all the same as in the preceding, except the ♂ scent-organ; a bent stripe obliquely running from the rise of the upper median vein to the middle of the submedian and being parted by the lower median vein.

T. zalates G. & S. (186 f) is above uni-coloured blackish-brown, with a darker stigma. Beneath somewhat lighter, more reddish, the proximal margin of the forewing near the anal angle still lighter. Costa Rica.

T. hemeterius Plötz (186 g) may perhaps belong hereto, since it shows the same scent-stripe, but the forewing is somewhat longer, the apex more produced. The blackish-brown forewing exhibits one small white postdiscal and subapical punctiform spot each. Beneath the same, in the disc of the forewing darkened; on the hindwing there are behind the lower cell-angle also 2 minute white dots. Patria unknown. GODMAN mentions a couple of the same species from Cuba without the white spots; this form may be denominated: *godmani* form. nov.

T. samedra H.-Schäff. (= *erebina* Plötz) (186 g) is not identical with *Rinthon cynea* (185 h), but owing to the quite different scent-organ it much rather belongs hereto, although it does not quite match to it; the stigma consists of a stripe between the median veins on the median and a very short part below it in the same direction. The species entirely resembles *hemeterius* above, but it has one more postdiscal spot between the median veins. Beneath somewhat lighter, more reddish brown, in the disc of the forewing black; the hindwing shows some insignificant postcellular accumulations of greyish-white scales. Brazil.

T. aphilos H.-Schäff. (= *obeda* Btlr.) (186 g) may also be ranged into this group of species. Above blackish-brown with one postdiscal and 3 subapical small white spots. Fringes of hindwings white, on the hindwing smoky. Beneath somewhat more reddish brown. Venezuela.

T. cyrus Plötz (= *duroca* Plötz) (186 g) is placed to *aphilos* by GODMAN. Above blackish-brown, with a greenish reflection on the body and base of the wings, and 2 small white postdiscal spots. Beneath the same, but somewhat more reddish. Rio de Janeiro.

T. misera Schs. may provisionally be inserted here. Above dark brown with blackish fringes and a long, narrow scent-stripe below the cell between the median veins and from there twice interrupted to the submedian. Beneath brighter brown, the hindwing with 2 small yellow spots behind the cell, one behind the upper, the other behind the lower cell-angle. Expanse of wings: 40 mm. Petropolis, also in Trinidad.

135. Genus: **Eutyichide** G. & S.

Antennae half as long as the costal margin. Otherwise very closely allied to *Cobalus* from which it differs by the lower median vein of the forewing rising before the middle of the cell; hindwing analwards produced. The stigma is composed of a very much extended, acute-angled part between the bases of the two median veins, a longitudinal stripe below it and a third similar one on the submedian.

E. cingulicornis H.-Schäff. (186 g) is above brown, behind the cell of the forewing there are 3 white spots in a straight row, subapically there are 1 or (in southern specimens) 2 small spots, and there is often also a cellular spot. The hindwing exhibits 2 small spots behind the cell, which are absent in southern specimens. Beneath the costal margin of the forewing is reddish-yellow in the basal half, the anal angle light grey; the hindwing is in the basal third lilac-whitish grey, distally red-brown. Antennal club at the base curled yellow. Guatemala to Brazil, also in Trinidad.

E. complana H.-Schäff. (= *midia* Hew., *gura* Plötz, *favetta* Plötz) (186 g, h) is much larger; on the forewing there are only 2 yellowish postdiscal spots and 3 subapical ones; the hindwing is uni-coloured. Beneath the same, scarcely lighter, the hindwing with 1 or 2 yellowish dots behind the cell. Head and body are haired greenish. Mexico to Venezuela.

E. ochus G. & S. (186 h) is smaller, with smaller spots, the green on the body scarcely traceable; it also greatly resembles *Rinthon cynea* (185 h), but it is separated by the scent-organ and the absence of the light anal angle on the forewing beneath. Mexico to Guiana and the Amazon, and from Trinidad.

E. orthos G. & S. (186 h) is still smaller than *ochus*, the subapical dots are absent. On the under surface the proximal margin of the forewing is lighter, the stigma above much less developed and finer. Head and body are greenish, the abdomen beneath white. Panama.

E. lycortas G. & S. (186 h) resembles *ochus* above, but it differs above by a submedian, oblong, white spot of the forewing. Beneath very different, the submedian spot extraordinarily large, greyish-white; costal margin chestnut-coloured, in the apex with an oblique silvery line, the distal margin lighter grey; on the hindwing the costal margin is broadly chestnut-brown, the distal margin strewn with a lighter grey, with an indistinct light grey band from the apex to the cell-end, proximal margin purple-brown. Mexico.

- achelous*. **E. achelous** Plötz (= *paria* Plötz) (186 h). Above lustrous blackish-brown, not spotted, stigma of the same colour, very well developed; head and thorax with green hair. Beneath the proximal margin of the forewing is more whitish than in the preceding. Panama, Venezuela.
- umber*. **E. umber** H.-Schäff. is above the same. Beneath lighter, proximal margin of forewing and anal angle whitish as well as a spot behind the cell, apex, costal margin and hindwing reddish. From *Mnasinous patage* (177 g), which it resembles above, it is separated by the very well developed stigma. Panama.
- asemat*. **E. asema** Mab. (186 h). The colouring above is more dull greyish-brown, the stigma of the same colour. Beneath lighter, on the hindwing scantily strewn with whitish; behind the cell there are 3 black dots. Honduras, British Guiana.
- subsordidus*. **E. subsordidus** Mab. looks above like the preceding, but scantily strewn with yellowish and has thereby a brownish effect. The hindwing is darker at the costal margin. The under surface is lighter, the forewing in the costal half and the whole hindwing strewn with ochreous-yellow, the margining of the eyes and palpi are likewise ochreous-yellow. Honduras.
- leptosema*. **E. leptosema** Mab. Blackish-brown with dark grey fringes, behind the black scent-spot there is a light yellow part. The under surface is reddish, in the proximal half of the forewing blackish, in the middle lighter yellowish-grey, the broadest below the median. Body black, the last abdominal ring ferruginous-brown. Expanse of wings: 36 mm. Rio Grande.
- phaetusa*. **E. phaetusa** Hew. Above dark red-brown, on the forewing with 6 silvery-white, transparent spots: one in the cell, 3 postdiscal ones and 2 subapical ones, hindwing with 2 small spots behind the cell. Beneath coloured the same, the lowest postdiscal spot is very much enlarged and united with that above it; the basal half of the costal margin and the apex is striped ochreous-yellow; the base of the hindwing is broad white, marked with indistinct brown spots. Expanse of wings: 1½ inch. Ega.
- astiga*. **E. astiga** Schs. Above brown, forewing at the proximal margin darker; between the median veins there is a small, olive-yellowish spot and farther distally above it another one. On the under surface the costal margin of the forewing and the apex are broad, the distal margin narrowly olive-brown, the rest black. Hindwing olive-brown with a small, black spot between the median veins and another one between the lower radial veins close at the cell-end, behind it some lighter diffuse spots. Expanse of wings: 27 mm. Castro, Paraná.
- candallariae*. **E. candallariae** Strand. Above blackish-brown, especially on the hindwing with some yellowish hair. Forewing with 2 whitish subapical and 2 postdiscal spots, the lower of which represents an angle being open towards the margin. Beneath deeper black, the lowest spot yellowish, behind it a yellow inner-angular patch; the hindwing with an almost rectangularly broken lighter band before and a similar broader brownish-yellow one behind the middle. Expanse of wings: 26 mm. Costa Rica.
- petrovna*. **E. petrovna** Schs. is above dark brown, without markings, with greyish-brown fringes, beneath scantily strewn with grey. This species is easily recognizable by the somewhat different scent-spot: on both sides of the lower median vein not sharply defined stripes extend to about one fifth of the length of the vein, and a black thickening along the submedian from the middle almost to the base. Expanse of wings: 30 mm. Petropolis.
- barnesi*. **E. barnesi** Schs. Thorax with dark green hair; the dark brown wings are tinted olive. Forewing in the basal half of the proximal margin with some whitish hair; between the median veins there is a large, hyaline white spot, a smaller one above it nearer at the distal margin, and a very small subapical one. Fringes of the hindwing at the anal angle white; a white spot is behind the lower cell-angle, parted by the upper median vein into a larger upper half and a small lower half. Beneath darker, apex of forewing dusted with lilac, before the distal margin very small dark spots. Hindwing lilac-brown with a dark basal shade and a broad oblique shade from the apex to the dark proximal margin; before the distal margin there are small dark spots between the veins. Expanse of wings: 30 mm. Petropolis.
- sabina*. **E. sabina** Plötz (186 h). Above blackish-brown with 2 small, in the ♀ larger and quadrangular white postdiscal spots and 3 subapical dots. Fringes of the hindwing white, on the forewing smoky. Beneath the species resembles a *Cymaenes*. Apex of the forewing, and hindwing light grey, in the ♀ more yellowish-reddish striated with red-brown, the most densely so at the costal margin and analwards with 3 dark, confluent spots at the lower cell-end; the costal margin of the forewing is broad red-brown. Brazil (Novo Friburgo).

136. Genus: **Phanes** G. & S.

Antennae somewhat longer, palpi as in the preceding. The ♂ scent-spot is angular, the larger side along the median between the veins, the shorter side along the lower median vein.

justinianus. **Ph. justinianus** Latr. (aletes *Hbn.*) (186 i). Above like *Eutycheide lycortas* (186 h), beneath blackish-brown, the forewing analwards lighter. Disc of the hindwing ochreous-yellow, bordered by dark spots, otherwise dusted lilac like the apex of the forewing. Antennal club basally curled yellow. Mexico to Brazil.

almoda. **Ph. almoda** Hew. (186 i). Above blackish-brown with 3 white postdiscal spots and 2 small subapical dots. Beneath the costal part and apex of the forewing is light lilac like the hindwing; all the veins light yellowish

on both sides finely bordered with black; at the cell-end there is a large yellow spot, on both sides bordered with black, and before the distal margin a row of small black spots; fringes speckled somewhat darker. From Brazil.

Ph. rezia Plötz (= *metanira* Mab.) (186 i) is somewhat smaller, above the same. Beneath the veins are not striped lighter, and the yellow cellular spot is absent, only the black spots are present; the submarginal row on the hindwing is not quite parallel to the distal margin, but somewhat deposited below the apex. Brazil.

Ph. cumbre Schs. Above brown with greyish-brown fringes, forewing with 3 small subapical and 2 postdiscal hyaline white spots, the lower being larger. Beneath the same, the costal margin of the forewing tinted reddish, apex and upper half of the distal margin dark grey. Hindwing beneath greyish-brown, in the disc darker, tinted reddish; at the cell-end there is a small light spot, behind it in a bent row several small light spots, the veins and a marginal line darker. Expanse of wings: 26 mm. Petropolis.

Ph. tavola Schs. is larger than the preceding with but one subapical dot and 2 postdiscal spots. Beneath the base of the forewing is blackish, the costal margin and apex dusted reddish. Hindwing likewise dusted reddish with a very small, grey distal-marginal spot above the upper median vein. Expanse of wings: 30 mm. Trinidad.

Ph. sylvia Kaye seems to be very closely allied to *tavola*. Blackish brown with 2 white postdiscal spots, the lower rectangular close beneath the lower cell-angle, the upper more quadrangular farther distally; 3 subapical dots. Beneath tinted more reddish, veins lighter brownish, on the hindwing a row of oblong, grey, small spots. Ventrums whitish, the 2nd palpal joint orange and black. Expanse of wings: 30 mm. Trinidad.

Ph. ochroneura Mab. It is questionable whether it may be placed to this genus. Above ferruginous black, hindwings rounded. Fringes yellowish-grey, on the forewing somewhat darker with 2 small subapical dots and 3 yellow postdiscal spots. Forewing beneath black, the veins at the costal margin and apex deep yellow. Hindwing likewise black, with ferruginous yellow veins, the proximal margin dull black, with a yellow longitudinal ray, and a postdiscal row of yellow dots, before the fringes with another similar small streak. Expanse of wings: 32 mm. Massauary.

137. Genus: **Euroto** G. & S.

Separated from *Eutyche* by a different stigma: one stripe is situate on the median between the two branches, another shorter one below it.

E. compta Btlr. (= *geisa* Mschr.) (186 i). Brown with 2 postdiscal and 1 to 3 subapical small spots on the forewing. Beneath as above, but lighter, forewing towards the anal angle with an indistinct small ochreous band. Veins of hindwings light ochreous-yellow, at the cell-end there is an ochreous-yellow punctiform spot and in a bent row 6 behind it. Panama to Colombia and Brazil; Trinidad.

E. lyde G. & S. (186 i) differs from *compta* above by only one minute dot between the median and lower radial vein, and 3 subapical dots. Beneath the proximal and distal margins are lighter; the hindwing shows behind the middle and before the distal margin lilac transverse bands, the basal area is spotted somewhat lilac. Mexico to Costa Rica.

E. micythus G. & S. (186 i) is above like *lyde* or also without any spots, very variable. Beneath lighter, on the forewing the costal margin and apex are more reddish than the whole hindwing, the forewing is lighter at the anal angle. On the hindwing at the cell-end a light ochreous-yellow dot and below it 2 or 3 more. Mexico to Costa Rica.

E. chlorocephala G. & S. (186 i) is above without any spots, with a large black stigma; head and thorax are green, the eyes very large. The under surface is lighter with 2 or 3 small lighter postdiscal spots; the hindwing exhibits a cell-end dot and 2 or 3 more in a bent row behind it. Panama.

E. oeagrus G. & S. (187 a). Above brown with 2 very large, coherent, yellow-hyaline postdiscal spots, and a subapical one; the costal-marginal area, the submedian area and the proximal part of the hindwing is above strewn with golden yellow. Beneath as above, the costal margin, apex and hindwing strewn with golden yellow, fringes ochreous-yellow. Costa Rica.

E. etelka Schs. Dark brown, ends of fringes grey. Forewing with 2 white subapical dots and 2 very small postdiscal spots. Beneath brown, distal margin of the forewing not dusted, the spots large. Hindwing at the proximal margin brown, otherwise violet with light brown veins; at the cell-end there is a small lilac spot, behind it in 2 rows lilac spots. Expanse of wings: 28 mm. Trinidad.

E. coler Schs. is above plainly dark brown, hindwing at the proximal margin blackish. Beneath the same with accumulations of minute yellow scales in a bent row behind the cell. Expanse of wings: 25 mm. Novo Friburgo.

E. hyperythrus Kaye is above dark reddish brown; behind the cell of the forewing there are 2 small hyaline spots, below them 2 larger ones. Beneath the marginal area of the forewing is lighter brown than the base and cell, the disc of the hindwing is reddish. Expanse of wings: 28 mm. From Trinidad.

E. simplicissima Kaye. Above brownish-ochreous; below and behind the lower cell-angle of the forewing there are 2 white, small hyaline spots, subapically 3 minute dots. On the hindwing the costal margin is darker. Beneath the proximal part of the forewing is blackish, the proximal angle lighter, hindwing unicoloured brownish-ochreous. Expanse of wings: 32 mm. Trinidad.

cocoa. **E. cocoa** *Kaye* is larger than the preceding, brownish-black, the basal half of the costal margin scaled golden; postdiscally there are 3 yellowish hyaline spots, the lowest of which is the largest; in the continuation there are 2 subapical dots. Hindwing more intensely scaled greenish golden. The forewing beneath is proximally blackish; hindwing brownish, somewhat iridescent with an indistinct row of lighter postdiscal spots. Expanse of wings: 34 mm. Trinidad.

purgis. **E. purgis** *Schs.* Above uni-coloured dark brown, beneath the same. Hindwing dark reddish-brown with a small white patch at the cell-end and a similar one behind it below the lower median vein; before the distal margin there is between the radial veins a large white spot and 2 smaller ones below it. Expanse of wings: 27 mm. Petropolis.

ritans. **E. ritans** *Schs.* Wings dark brown; the scent-spot extends below the median to the upper median vein. The under surface is likewise dark brown, the hindwing dusted reddish with a small yellow postdiscal spot near the apex and 2 others nearer to the anal angle. Expanse of wings: 25 mm. Petropolis.

138. Genus: **Phlebodes** *Hbn.*

Palpal terminal joint conical, very short; on the forewing the middle radial vein is strongly bent down at the base. Hindwing at the anal angle somewhat prolonged. The scent-stripe extends from the rise of the upper median vein to the middle of the submedian.

tiberius. **Ph. tiberius** *Mschlr.* (= *pertinax* *Wts.* nec *Cr.*) (187 a). Above brown, the grey stigma is on both sides bordered with black; behind and below the cell of the forewing there are 4 spots in a bent row, the uppermost is very small, or also entirely absent; besides there are 3 subapical dots, all of them ochreous-yellowish. The under surface is lighter, the costal margin and apex of the forewing ochreous-yellow, the spots indistinct; the costal margin of the hindwing is broad yellowish like a transverse row of spots behind the cell. Mexico to Colombia and Guiana; Trinidad.

pertinax. **Ph. pertinax** *Cr.* (187 a, b). Above blackish-brown, with a white cellular spot, 2 postdiscal ones behind it and 2 subapical dots; besides a submedian yellowish patch. Hindwing analwards with 2 or 3 lighter dots near the distal margin. Beneath the apex of the forewing and the hindwing shows a steel-blue reflection, with fine yellowish veins and a postdiscal row of 5 small whitish dots. Surinam.

reticulata. **Ph. reticulata** *Plötz* (= *meton* *Mab.*, *suffenas* *Mab.*) (187 a). Jet-black, costal margin of forewing as far as the cell-end, and the submedian space are light reddish-yellow; an indented band extends from the apex to the lower median vein, it is below gnawed out and behind separated from the reddish-yellow colour by a black streak. Hindwing black with a reddish-yellow, rounded discal spot separated by the veins. Beneath the forewing is yellowish at the costal and distal margins, in the disc blackish, the oblique band only feebly pronounced. Hindwing dirty yellow, postdiscally darkened, in it a lighter band from the costal fold to the inner-marginal fold, analwards more yellow. Expanse of wings: 27 mm. Teffé.

matuta. **Ph. matuta** *Plötz* (187 b) is perhaps allied to *reticulata* (187 a) and differs by the orange band of the forewing being composed more of separate and smaller spots. The hindwing, however, is very much more extensively orange, with fine black veins, and uniformly narrow black margins. Patria unknown.

vetula. **Ph. vetula** *Mab.* approximates *pertinax* *Cr.* (187 a, b). Blackish-brown, fringes grey. Beneath browner, disc of forewing blackish-brown, at the apex with yellow veins, at the proximal angle light. Hindwing blackish-brown, with yellow veins. Brazil.

voranus. **Ph. voranus** *Mab.* doubtfully belongs to this genus. Ferruginous black, the costal margin of the forewing as far as the cell-end reddish-yellow; at the apex begins a reddish-yellow band and expands to the submedian, being divided by the veins into 6 dissimilar spots, proximally to it there is the black scent-stripe. Hindwing ferruginous-brown with short reddish-yellow postdiscal spots. Beneath the forewing is light reddish brown, in the middle and at the base blackish, the macular band lighter than above. Hindwing yellowish-brown with a broad whitish-yellow band extending from the costal margin across the cell-end to the inner-marginal fold. Expanse of wings: 27 mm. Colombia.

trebius. **Ph. trebius** *Mab.* Light brown with 3 small subapical dots and a white postdiscal spot behind the cell; hindwing with yellow hair. Forewing beneath brown, at the costal margin red-brown, the dots somewhat larger and one more at the lower cell-end, the distal margin being lilac-grey. Hindwing blackish, at the base darker, towards the apex with 2 lighter quadrangular spots. Expanse of wings: 27 mm. Bogotá.

iheringii. **Ph. iheringii** *Mab.* Above blackish or olive-brown, on the forewing with 3 white subapical hyaline dots and 2 small postdiscal spots. Fringes of the forewing brown, at the hindwing ochreous. Beneath the forewing is blackish at the base, at the costal margin as far as the hyaline dots reddish, and below the discal spots lighter yellowish. Base of hindwing blackish, in the marginal area yellowish or reddish-grey or also reddish-yellow, always lighter. Expanse of wings: 27 to 28 mm. Rio Grande do Sul.

mengeli. **Ph. mengeli** *Weeks* is doubtfully placed here. Above dark brown with 2 minute white subapical spots, a larger one behind the lower cell-end and below it 2 small ones next to each other. Stigma black. Hindwing dark brown with 4 whitish, small indistinct spots towards the apex behind the cell towards the anal angle. Beneath somewhat lighter brown, near the anal angle of the forewing dusted with whitish. Hindwing light

brown, with lighter veins, the light spots connected more like a band: in the disc before them there are traces of a similar band. Expanse of wings: 1.1 inch. Venezuela (Suapure).

Ph. metonidia Schs. Above dark brown, basal half of costal margin of the forewing ochreous-yellow; a postdiscal row of bright yellow spots, those between the radial veins being very small, below the cell proximally bent and bordering distally on the stigma. Hindwing with greenish ochreous hair, with a postdiscal row of ochreous-yellow, small spots. Beneath the base and proximal margin of the forewing is blackish, the costa and apex dark ochreous-yellow, spots as above, but darker. Hindwing ochreous-yellow, with yellow veins, the small postdiscal spots very indistinct. Expanse of wings: 27 mm. Brazil (Tijuca). *metonidia.*

Ph. fartuga Schs. is above dark brown with reddish yellow fringes. Forewing with bright yellow spots behind the cell and submedian, the latter and the two upper ones very small, that between the median veins large. Hindwing without markings, with ochreous-brown hair. Beneath the colour is violettish-brown, the veins ochreous-yellow; forewing in the disc and at the proximal margin blackish, the submedian spot is absent. Expanse of wings: 24 mm. Novo Friburgo. *fartuga.*

Ph. gulala Schs. Above dark brown with grey fringes; forewing at the costal margin above the cell with yellow hair; behind the stigma there is a yellow diffuse spot; between the median veins and above them there is one distally concave hyaline spot each. Hindwing haired olive, with a yellowish-patch behind the lower cell-angle. Beneath olive-brown, proximal margin of forewing blackish, with a whitish submedian spot; hindwing with 2 small yellow spots below and behind the cell. Expanse of wings: 34 mm. Brazil (Tijuca). *gulala.*

Ph. chittara Schs. is much smaller, otherwise above similar; the yellow hairing of the costal margin is absent; the 2 postdiscal spots are whitish hyaline, and a small round subapical spot. On the hindwing there are 2 small, faint, yellow spots behind the cell. Beneath the costal margin and apex of the forewing are strewn with a yellowish grey, hindwing entirely yellowish-grey with a small white spot at the lower cell-angle and 3 small round spots behind it, 2 analwards, one farther apically. Expanse of wings: 29 mm. Trinidad. *chittara.*

Ph. unia Btlr. (187 b). Above dark brown with 3 small subapical and 3 larger postdiscal spots; hindwing with an ochreous-yellow wedge-shaped stripe bending round behind the cell towards the apex. Fringes at the anal angle of the forewing, and the whole hindwing ochreous. Beneath the hindwing is yellow with small, indistinct, brownish antemarginal spots, 2 larger, dark brown postcellular spots and 5 postdiscal white spots. Brazil. *unia.*

Ph. odilia Plötz (187 b) is very similar, above the same, beneath lighter, at the costal margin of the forewing and apex red-brown and lighter grey; the hindwing is very light reddish sand-coloured, without the white spots of the preceding. Brazil. *odilia.*

139. Genus: **Lerema** Seddr.

Antennae shorter than half the costal margin; club with a long reverted apex. Last joint of the palp short, conical. On the forewing the middle radial is basally only slightly bent. Middle tibiae spined. The scent-scale spot of the ♂ consists of a thick, indented, interrupted stripe extending from the rise of the upper median vein to the submedian.

L. accius Abb. & Smith. (= *monoco* Seddr., *nortonii* Edw., *punctella* Grt. & Rob., *ceramina* H.-Schäff., *pattenii* Seddr., *phocyliides* Plötz) (187 b). The upper surface is blackish-brown with 3 white, subapical small spots and 3 somewhat larger, but more or less dark dusted or blurred postdiscal ones. Beneath the costal margin of the forewing is ochreous, the apex and hindwing greyish brown with a slight lilac reflection, and a postdiscal and an antemarginal band of dark spots; the uppermost proximal spot is removed far inwards. Sometimes the colour of the hindwing is also mixed a little with red-brown. North America to Brazil. — f. **dido** Plötz is a form from Venezuela, beneath more variegated, tinted ferruginous-red. *accius.*

L. mooreana Dyar is similar to *accius* (187 b), but the ♀ has a white, not transparent spot above the submedian, and a quadrangular one above it. Beneath tinted ochreous, disc of forewing black; on the hindwing there are 5 small, light postdiscal spots in an oblique line, the uppermost being removed inwards. Expanse of wings: 28 to 30 mm. British Guiana. It was bred from larvae on the sugar-plant. *mooreana.*

L. parumpunctata H.-Schäff. (187 c) is much larger, the ♂ only with minute subapical dots above and one postdiscal dot at most. Beneath the hindwing is more variegated, in the costal-marginal half cerise, mixed with ferruginous-brown and lilac, with a postdiscal band, the antemarginal band being absent. Venezuela, Brazil. *parumpunctata.*

L. leptosema Mab. Blackish-brown, fringes dark grey; the stigma is distally brightened up by yellow. Beneath more reddish, in the proximal half of the forewing blackish, in the middle yellowish-grey, the broadest between the median veins. Expanse of wings: 36 mm. Rio Grande. *leptosema.*

L. lochius Plötz (= *bipunctata* Mab., *asella* H.-Schäff.) (187 c) very much resembles *parumpunctata*; above only with 3 white subapical dots, fringes yellowish-grey. Beneath much darker and less variegated, without any red and ferruginous yellow tints, similarly coloured and marked as *accius*. Venezuela. *lochius.*

L. peneia G. & S. (187 c) differs from *accius* by 2 small ochreous-yellow spots behind the stigma; the stigma itself is narrower. Panama. *peneia.*

L. coyana Schs. (187 d). Dark brown, with a faint green reflection towards the base; stigma dark grey; on the forewing with a small postdiscal and a minute subapical spot. Beneath reddish-brown, towards *coyana.*

the base below the costal margin of the forewing blackish, anal angle greyish-brown. Hindwing with 2 small whitish spots behind the lower cell-angle and a subapical one. Expanse of wings: 33 mm. Petropolis.

stacura. **L. stacura** Schs. Above brown with a dark marginal line and lighter fringes, forewing basally at the proximal margin haired olive. The under surface is brown, at the costal margin, apex and distal margin of the forewing olive brown, the proximal margin and anal angle yellowish-white. Hindwing olive-brown with darker markings: a short, proximal transverse line and spot, an irregular median row of small spots, a broad shade from the apex to the cell-end and towards the proximal margin, and some diffuse patches before the distal margin. The ♀ forewing shows 2 postdiscal and 3 subapical white spots, the under surface is strewn with a more greenish yellow. Expanse of wings: 33 to 34 mm. Petropolis.

postpuncta. **L. postpuncta** sp. nov. (187 c). Above dark brown, strewn with yellowish, 2 postdiscal small spots and one in the lower cell-angle, as well as a subapical dot are yellowish-white, 4 small spots behind the cell of the hindwing are more ferruginous-yellow. Fringes lighter, distally almost whitish. Beneath the costal margin of the forewing and the apex as well as the hindwings are light reddish-brown; the lower half of the forewing blackish; the spots of the hindwing are more indistinct than above, the fringes not lighter than the ground of the wings. From the Rio Songo (Bolivia).

exclamationis. **L. exclamationis** Mab. is above jet-black with a brownish-red reflection in the disc, on the forewing with 3 minute apical dots and 2 yellowish-white spots between the median veins, which are linear like fragments of an oblique stripe distally appressed to the jet-black scent-spot. Hindwing without spots, with blackish fringes. Beneath as above, at the proximal margin of the forewing paler; hindwing black with 4 light dots in a semi-circle. Bolivia.

subgrisea. **L. subgrisea** Mab. It is doubtful whether this species and the preceding belong at any rate to this genus. Olive-brown with a yellowish reflection. Forewing with 3 very small apical dots and 2 small, yellowish, blurred spots between the median veins; the scent-stripe is faint; the costal margin is darker than the rest of the wing, the fringes light ash-grey. Forewing beneath grey, in the proximal half as far as the spots blackish, at the costal margin grey, the inner-marginal area yellowish-grey. Hindwing grey with a reddish shine and strewn with black, especially at the costal margin; proximal margin grey, haired reddish-yellow; occasionally there appear 3 or 4 small grey spots behind the cell. Bolivia.

mulla. **L. mulla** Plötz (187 d). Above blackish-brown, the scent-stripe distally with a slight silvery grey reflection, behind its upper end there is a minute, white postdiscal dot, subapically 2 or 3. Hindwing without markings, with lighter, somewhat yellowish fringes. Beneath the forewing is lighter brown at the costal margin, apex and distal margin, in the disc there are 2 white dots. Hindwing brownish-grey, behind the lower cell-angle in an oblique row with 3 or 4 small light dots. Described from Surinam.

elgina. **L. elgina** Schs. Above dark brown, with a small postdiscal spot behind the lower cell-end and a subapical one. Beneath the forewing is dusted reddish-brown at the costal margin and apex. Hindwing dark reddish-brown with a small yellow spot at the lower cell-angle and a subapical one. Expanse of wings: 37 mm. Novo Friburgo.

hypozonea. **L. hypozonea** Dyar (187 d) is bronze-black, forewing with a series of small yellowish spots, one being submedian, a larger quadrangular one between the median veins, 2 small ones behind the cell, removed farther distally, and 3 subapical ones. Disc of hindwing haired yellowish. Beneath dusted whitish, especially the hindwing, except the apex, with a broad, whitish, bent median band. Mexico (Guerrero).

miqua. **L. miqua** Dyar is allied to *lochius* (187 c), but whereas in the latter the bands of the hindwing beneath are parallel and oblique to the costal margin, here the proximal one is rectangularly flawed to the costa, the distal one being so much bent that it also touches the costal margin in a right angle. Peru (San Miguel).

amblyspila. **L. amblyspila** Mab. Upper surface dark brown with a yellowish reflection in the marginal area; forewing with 3 indistinct yellow subapical dots; behind the cell there are 2 more dots being more distinct and not transparent; stigma jet-black, fringes yellowish-grey. Hindwing blackish with a small yellow dot behind the lower cell-angle. Beneath blackish, in the middle of the proximal margin grey, in the middle of the distal margin black; the spots are purer white, the middle one longer. Hindwing greyish-brown with a lighter curved band dying away behind the cell; proximal margin lighter. Bolivia.

crassinota. **L. crassinota** Mab. is similar, but much larger; wings above olive brown with a yellowish lustre in the disc, with 3 small yellowish subapical dots and a larger spot behind the lower cell-angle; the scent-scale stripe, distally reflecting yellowish, is very distinctly bipartite by the lower median vein; fringes ashy-white. Hindwing yellowish with a lighter part behind the cell. Forewing beneath light reddish or reddish-grey, in the basal part blackish as far as the discal spot which is here more distinct; below it another spot. Hindwing reddish-grey with a postdiscal lighter band; at the margin there is a black line with small spots at the ends of the veins. Bolivia.

loammi. **L. loammi** Whitn. (= *regulus* Edw.). Above lustrous dark brown, fringes lighter; forewing with 3 quadrangular, small, subcostal spots, a larger postdiscal one below the cell, and a strigiform one below it. Beneath dark chestnut-coloured, apex of forewing and border of hindwing dusted pearl-coloured grey, spots as above, with 2 more between them; hindwing with subbasal and antemarginal, irregularly bent rows of white spots, bordered with black. The ♀ is somewhat lighter, the spots increased. Florida (Jacksonville), taken in March.

horus. **L. horus** Edw. is above uniformly brown, in the disc of the forewing somewhat lighter. Beneath brown, on the forewing with 2 or 3 small whitish subapical dots and postdiscal patches indicated by white scales. Texas.

L. lunus *Edw.* Forewing above dark brown with 3 semi-transparent, small subapical spots, a large, *lunus*. hour-glass shaped cellular spot, and 2 postdiscal ones, the upper one being streak-shaped, the lower one large quadrangular. Beneath dark brown, apex of forewing densely dusted with grey with the spots of the upper surface. Hindwing only little dusted with grey, with 2 blackish spots in the middle, in the distal one there is a fine white streak. The ♀ has somewhat larger spots and one more postdiscally. Arizona.

L. deva *Edw.* is very similar, the spots are smaller, beneath greyer, on the hindwing only one dark *deva*. spot without the white streak, fringes of the hindwing white, in *lunus* yellow. California, Arizona.

L. altama *Schs.* has only the upper part of the scent-stripe at the rise of the upper median vein, the *altama*. position being therefore only provisional here. Above dark brown, beneath bluish-grey, on the forewing with a small white stripe in the cell; from the posterior half of the cell a black shade extends between the median veins to the proximal angle, proximal margin whitish. Hindwing along the proximal margin lilac. The ♀ is lighter brown with a postdiscal band of white hyaline spots. Beneath more bluish, the inner-marginal stripe of the hindwing more reddish. Expanse of wings: 34 to 40 mm. Castro Paraná.

140. Genus: **Moeris** *G. & S.*

Distinguished from the preceding genus by a somewhat stunted apex of the forewing and the velvety black ♂ stigma not proceeding from the upper, but from the lower median vein, being otherwise shaped just like in *Lerema*.

M. striga *Hbn.* (187 d). Blackish-brown, at the costal margin of the forewing in the basal half scaled *striga*. ochreous-yellow. Beneath lighter, costa of forewing and apex broadly ochreous-yellow, marked chestnut-brown; hindwing marbled chestnut-brown, the costal margin towards the apex mixed with ochreous. In some specimens there are about 3 small subapical dots, 3 small postdiscal spots, and occasionally also a cellular spot. From Mexico to Argentina.

M. hyagnis *G. & S.* is above blackish-brown; beneath the forewing is lighter towards the anal angle, *hyagnis*. with a minute subapical dot. Hindwing with a whitish cell-end dot. Abdomen beneath whitish. It is also very much like *Mnasicles hicetaon* (p. 985), but the stigma is broader, the last joint of the palp shorter and obtuser. Mexico.

141. Genus: **Metron** *G. & S.*

Costal margin of forewing at the base somewhat convex. Veins little different, the middle radial at its rise near the lower. Middle tibiae with long spines. The ♂ exhibits a little visible stigma of 2 parts: a long stripe being situate on the median between the branches and being widened at its proximal end, a short stripe below it and a third still shorter one in the middle of the submedian.

M. chrysogaster *Btlr.* (= *fasciata* *Mschlr.*, *goza* *Hew.*, *cuneata* *Plötz*) (187 d). Blackish-brown with a *chryso-gaster*. golden yellow costal margin, 3 ochreous-yellow subapical dots which may also be absent, and 3 postdiscal spots. Disc of the hindwing indistinctly ochreous-yellow. Beneath the forewing is lighter, the spots are whiter and larger, the costal margin and apex tinted olive-yellow. The hindwing shows a straight, broad, whitish band from the costal margin to the proximal margin. Anal angle broad blackish-brown, otherwise olive. Abdomen beneath golden yellow. Mexico to the Amazon and Trinidad.

M. hypodesma *Plötz* (187 e) is very closely allied to the preceding and differs by its somewhat larger *hypodesma*. size and 4 postdiscal spots running in an oblique direction to the apex; the submedian one is small, that above it is the largest and quadrangular; another, subapical, small spot; in the ♂ the spots are more yellowish, in the ♀ white. Hindwing without spots. Beneath like *chrysogaster* except the increased spots, but the abdomen is brownish and not yellow. From Rio de Janeiro and Pará.

M. fascia *sp. nov.* (187 d). Above blackish-brown, on the forewing with a white subapical dot, 2 *fascia*. very small postdiscal spots and an ochreous-yellow submedian streak. Beneath somewhat duller brown, the forewing marked as above; the hindwing shows a very broad, silvery white, greenish iridescent discal band separated from the similarly coloured proximal margin by a black wedge-shaped spot; it is just as broad as the distal margin in its middle. Colombia (Rio Aguaca Valley) in the Coll. FASSL.

142. Genus: **Metrocles** *G. & S.*

Distinguished from *Metron* by the middle tibiae not being spined and an entirely different stigma; a broad, bent, interrupted scent-scale stripe extends from the rise of the lower median vein to the middle of the submedian.

M. leucogaster *G. & S.* (187 d, e) is very much like *Metron chrysogaster*, but the spots of the forewing *leucogaster*. are white, the stigma is quite different, and placed more like in *Lerema* and *Moeris*. The hindwing shows beneath a white band bordered with yellow. Abdomen beneath white bordered with yellowish. Panama.

M. hypochlora *sp. nov.* (187 e) is allied to the following. Above blackish-brown with a narrow ochreous- *hypochlora*. yellow band parted by the veins, and 2 subapical dots; hindwings uni-coloured. Beneath the forewing is blackish,

at the apex like the hindwing leek-green, the spots more whitish than above, the lowest very much widened towards the anal angle. The hindwing shows an almost straight, silvery white band, along the proximal margin a blackish, wedge-shaped spot. According to a ♂ of the Coll. FASSL from South Peru (Madre de dios).

zimra. **M. zimra** Hew. It is doubtful whether this species and the following belong hereto. Above red-brown with a postdiscal oblique band of 4 hyaline spots and 2 small subapical spots. Hindwing close behind the middle with an angular ochreous-yellow band; fringes light yellow. Beneath tinted green, marked as above, both wings with a submarginal band of ochreous-yellow spots, the hindwing besides with a yellow basal spot, the light yellow discal band is much broader and extends from the costal margin to the inner-marginal vein. Expanse of wings: $\frac{1}{4}$ inch. Brazil.

oropa. **M. oropa** Hew. (= *angulina* Plötz, *fasciata* Mschlr.) (187f) approaches the preceding, but on the forewing it exhibits a coherent, orange band from the costal margin to the middle of the proximal margin, on the hindwing also above an orange basal spot beside the discal band. Beneath the same, but the bands are almost white, the apex of the forewing is tinted green, the hindwing is green and the band extends farther towards the anal angle. The basal spot is situate less closely at the base than in *zimra*. Expanse of wings: $1\frac{1}{6}$ inch. Brazil.

verdanta. **M. verdanta** Weeks seems to belong hereto, if it is not synonymous to the preceding. Above dark brown, towards the base strewn somewhat tan-coloured, with 3 small subapical spots, below them removed farther towards the margin are 2 small and below them 3 large postdiscal spots, all of them reddish yellowish-brown. Hindwing dark brown with a broad tan-coloured band from the apex to the middle of the proximal margin. Beneath the wings are tan-coloured, at the costal margin and apex of the forewing and on the hindwing covered with green; the band of the hindwing is purely white. Expanse of wings: 1.15 inch. Venezuela (Suapure).

caligula. **M. caligula** Schs. may be provisionally inserted here. Above dark brown with lighter fringes and a fine scent-stripe at the transverse vein and a round scent-scale stripe between the lower median vein and cell. Beneath olive-brown, on the forewing with a darker cell-end streak; cell and base darkened, the apical half of the proximal margin light yellowish. Hindwing with a broad, white band from the apex to the proximal margin above the anal angle, shortly before the proximal margin interrupted by a light olive-brown stripe along the fold. Expanse of wings: 33 mm. Novo Friburgo.

143. Genus: **Papias** G. & S.

Distinguished from the preceding genera by the hindwing being somewhat prolonged at the anal angle; besides the ♂ is without the scent-organ.

integra. **P. integra** Mab. (187 e) is above deep blackish-brown, the under surface somewhat lighter, blackish-brown, towards the margin lighter, especially at the anal angle of the forewing. The band is dirty grey; the eyes are surrounded by a dark reddish-yellow colour. Mexico to Brazil.

dictys. **P. dictys** G. & S. (187 c) is smaller, beneath more reddish, mostly with a small, white subapical dot; on the hindwing beneath there are 3 small postdiscal dots. Mexico to Panama.

hycsos. **P. hycsos** Mab. Silky black with a ferruginous reflection in the disc, in it a small, diaphanous dot, above it a small one not transparent; 2 small, postdiscal, oblique spots, the lower twice as long; as far as the spots the proximal part of the wing is darker; fringes ferruginous yellow. Beneath the wing is deep blackish-brown, the forewing with a metallic violet reflection, the hindwing with a blue lustre or entirely violettish-blue. Expanse of wings: 28 mm. Colombia.

microsema. **P. microsema** G. & S. (= *phaeomelas* Hbn.) (187 e) is above the same; beneath more reddish, the anal angle of the forewing is much lighter, more extensive; on the forewing there are 2 postdiscal dots and a subapical one; on the hindwing beneath 4 whitish dots in a bent row. Mexico, Costa Rica, Panama, Brazil, Trinidad.

phainis. **P. phainis** G. & S. is the same, but beneath without any spots with differently shaped genitals. Mexico, Guatemala, Costa Rica.

rubida. **P. rubida** Plötz (187 e). Above blackish-brown, on the body and bases of the wings with a very faint greenish reflection. Beneath somewhat duller brown, apex of the forewing and the whole hindwing deep chestnut-coloured, with distinct black veins. From the somewhat similar *Eutychide umber* it differs by the black anal part of the forewing beneath and the absence of the cellular spot. Brazil.

derasa. **P. derasa** Plötz (187 f) is a much larger species, monotonously blackish-brown, with greyish-brown fringes. On the under surface the distal-marginal half of the forewing is lighter brown, towards the dark disc dentately defined. Rio de Janeiro.

subcostulata. **P. subcostulata** H.-Schäff. (187 f) is somewhat smaller than *derasa*, above the same, uni-coloured blackish-brown. Beneath the costal margin and apical half of the forewing and the hindwing is somewhat duller brown, with very fine light yellowish veins. Fringes with a slight ochreous reflection. From Brazil.

caura. **P. caura** Plötz (? = *tristissimus* Schs.) (187 g) is very much like *integra* (187 e); above uni-coloured brownish-black, beneath a little lighter, browner with a broad whitish-grey inner-marginal part of the forewing. From Surinam and Peru.

ctyanus. **P. ctyanus** Schs. Above dark brown, on the vertex and on the palpi haired yellowish. Beneath reddish-brown, the basal half of the forewing blackish; on the hindwing the inner-marginal part is light brown. Expanse of wings: 27 mm. From Trinidad and Novo Friburgo.

P. agassus *Mab.* Forewing jet-black, hindwing black with a very much indented distal margin. Beneath the forewing is black with a violet reflection, in the marginal area bluish-lilac, at the proximal angle lighter ferruginous. Hindwing black, from the cell to the distal margin dark lilac with 4 metallic blue spots behind the cell towards the apex, the 2 lower ones sagittiform, the others strigiform. Expanse of wings: 26 mm. Massauary. *agassus.*

P. bobae *Weeks* is above velvety blackish-brown with an indistinct darker band, hindwing at the costal margin somewhat lighter. Beneath somewhat lighter, thereby the dark bands become somewhat more distinct; inner-marginal part very light. Hindwing as above. Expanse of wings: 27 mm. Venezuela (Suapure). *bobae.*

P. leucopogon *Plötz* (187 f) has above on the base of the wing and on the body a faint greenish reflection. Beneath lighter brown, on the forewing two basal thirds are darkened, the distal third is lighter, with 3 small light subapical spots. Hindwing with a darkened base and a dark semi-transverse band from the middle of the costal margin to below the cell, behind it projecting somewhat towards the margin. Venezuela (Laguayra). *leucopogon.*

P. corisana *Plötz* (187 g) is above uni-coloured black; beneath lighter, more brownish, especially on the forewing analwards; here there are in the disc 2 whitish punctiform spots and above them 3 subapical ones. Hindwing likewise uni-coloured without markings, only at the proximal margin somewhat lighter. From Surinam. *corisana.*

P. sobrinus *Schs.* Above dark brown, fringes blackish, distally grey. Beneath dark brown, the forewing is lighter, with a postdiscal bent row of very small grey spots; the hindwing shows a postdiscal row of dark ochreous-yellow spots. Expanse of wings: 27 mm. Rio de Janeiro. *sobrinus.*

144. Genus: **Mnasinous** *G. & S.*

Antennae longer than half the costal margin, body slender. Middle tibiae bare. The ♂ shows a tripartite stigma which is rather inconspicuous: a faint scent-stripe along the median between the two veins, a shorter one below it and a longer one on the submedian.

M. patage *G. & S.* (187 g) is above monotonously blackish-brown, beneath somewhat lighter, the forewing at the proximal margin and anal angle still lighter; costal margin, apex and hindwing are dusted dark red. From Mexico and Panama. *patage.*

145. Genus: **Metiscus** *G. & S.*

Different from the preceding by the ♂ scent-organ: from the rise of the upper median vein a bent scent-scale stripe runs obliquely to the rise of the lower branch, below it there is a short stripe.

M. atheas *G. & S.* (? = *infuscata* *Plötz*?) (187 f). Above uni-coloured blackish-brown, the narrow bent stigma equally coloured. Beneath as above, only the forewing at the anal angle lighter, fringes grey. Mexico to the Amazon, Trinidad. *atheas.*

146. Genus: **Methion** *G. & S.*

Costal margin somewhat more convex than in the allied genera; middle tibiae bare; the ♂ is without a scent-scale stripe. The distal margin of the abdominal fold is long-haired.

M. melas *G. & S.* is monotonously blackish-brown, beneath somewhat more reddish, at the proximal margin and anal angle of the forewing lighter. Palpi intermixed with golden yellow hair. From Guatemala. *melas.*

147. Genus: **Thargella** *G. & S.*

The antennae are $\frac{2}{3}$ of the length of the costal margin; forewing short and broad with a very convex costal margin. Stigma absent. The proximal margin of the abdominal fold is long-haired.

Th. fuliginosa *G. & S.* Above blackish-brown, beneath red-brown, the forewing analwards lighter. Palpi golden yellow. Nicaragua to Colombia, British Guiana and the Amazon. *fuliginosa.*

148. Genus: **Mnasitheus** *G. & S.*

Antennae half as long as the costal margin; costal margin of forewing slightly bent. Middle tibiae bare, a stigma is only present in *cephis*: a short stripe above the lower median vein, a longer one below it and a still longer one on the submedian.

M. cephis *G. & S.* Above uni-coloured blackish-brown, beneath with a somewhat purple tint. Smaller than the very similar *Mnasalcas uniformis* with a different stigma. Distinguished from the following species by a longer terminal joint of the palp and different genitals. Mexico to Guatemala. *cephis.*

- simplicissimus.* **M. simplicissimus** H.-Schäff. (= *nigritulus* Mab., *insignis* Plötz, *facilis* Plötz) (187 k) is the same, but without a stigma, with shorter palpi beneath mixed with golden yellow. Fringes dark grey. South America, widely distributed as far as Trinidad.
- lurida.* **M. lurida** H.-Schäff. (187 g). Above monotonously blackish-brown. Beneath the costal-marginal part of the forewing is somewhat reddish, the distal margin of both wings is brightened up by a somewhat duller brown. Basal part and disc of the hindwing dark red-brown, at the costal margin extended to the apex. Described from Brazil.
- chrysophrys.* **M. chrysophrys** Mab. is likewise very closely allied, but it has somewhat longer antennae, bright yellow fringes, and an indistinct, bipartite stigma. Expanse of wings: 21 mm. Colombia.

149. Genus: **Mnasaleas** G. & S.

Antennae of $\frac{2}{3}$ the length of the costal margin, club stout with a long apex. The ♂ shows a tripartite stigma: a scent-stripe on the median between both veins, a short one below it, and a triangular part in the middle of the submedian.

- uniformis.* **M. uniformis** Btlr. Monotonously blackish-brown, beneath somewhat browner, with a lighter proximal margin of the forewing. Palpi haired blackish-brown. Costa Rica; Trinidad.
- amatala.* **M. amatala** Schs. Above dark brown, also at the base of the hindwing with an oblique scent-scale spot. Beneath likewise brown. Costal margin of forewing for two thirds, cell and basal half of the proximal margin darker, distally to it a row of indistinct, lighter spots. Hindwing dark violettish-brown in the basal 2 thirds, with some small postdiscal, indistinct, light spots. Expanse of wings: 31 mm. Novo Friburgo.
- circellata.* **M. circellata** Plötz (187 h) according to the figure by the shape of the scent-organ belongs hereto and is perhaps to be combined with *amatala*. Above blackish-brown, fringes somewhat ochreous-brownish. Beneath browner, basally darkened, on the fore- and hindwings with some small, postdiscal, light indistinct spots, the hindwing also shows a cellular dot. Brazil.

150. Genus: **Mastor** G. & S.

Antennae half as long as the costal margin. Costal margin of forewing at the base convex. Middle tibiae spined. The ♂ has an oblique scent-stripe from the rise of the upper median vein to the middle of the submedian (the stigma is absent in *M. perigenes*).

- anubis.* **M. anubis** G. & S. (= *perloides* Plötz) (187 g). Blackish-brown with a stigma of the same colour; beneath the same, palpi intermixed with golden yellow hair; the base of the antennal club beneath and distally ochreous-yellow; sometimes there is on the hindwing beneath a postdiscal row of ochreous-yellow dots. Mexico.
- bellus.* **M. bellus** Edw. (187 h) is easily discernible by the ochreous-yellow fringes of the wings. Arizona, Mexico in May. — *phylace* Edw. (187 g), according to recent reports, seems to be a second stock of *bellus*. It differs by the head and collar being golden yellow, the fringes, however, dirty grey. In this case *phylace* (187 h) would have to be the name of the species, and *bellus* its first form of generation. From Colorado, Arizona and New Mexico in July.
- perla.* **M. perla** Plötz (187 g) is larger, above blackish-brown, with ash-grey fringes and similar hairing of the body. Beneath on the forewing somewhat lighter, the hindwing ash-coloured, with fine darker veins, a whitish cellular spot and 4 small postdiscal dots in the apical half. Rio de Janeiro.
- perigenes.* **M. perigenes** G. & S. (187 g) is easily recognizable by the absence of the stigma and the hindwing beneath being peculiarly radiantly striped brownish and whitish. Mexico.

151. Genus: **Mnasilus** G. & S.

Distinguished from the allied genera by a hair-pencil on the forewing above below the submedian. Middle tibiae spined; stigma absent.

- penicillatus.* **Mn. penicillatus** G. & S. (= *zalma* Plötz) (187 h) somewhat resembles above *Metron chrysogaster* (187 d), but the ochreous spots form a complete oblique row as far as below the apex. Beneath somewhat lighter; hindwing with 5 lighter dots in a bent row. Mexico to the Amazon and Brazil.
- sucova.* **Mn. sucova** Schs. has the hair-pencil below the base of the median and may therefore be best inserted here. Above blackish-brown, fringes lighter, forewing with a somewhat darker shade at the cell-end. Beneath the forewing is blackish at the base, violettish-brown at the apex and costal margin; a small whitish hair-spot behind the lower cell-end. Hindwing violettish-brown with a bent row of small grey diffuse patches behind the cell. Expanse of wings: 29 mm. Petropolis.

152. Genus: **Vehilius** G. & S.

Antennae somewhat longer than half the costal margin. Otherwise the same as the following genus *Megistias* from which it differs by a different structure of the ♂ genitals. Middle tibiae with very long spines.

V. illudens Mab. (187 h). Blackish-brown, 2 postdiscal spots and 2 or 3 subapical dots are ochreous-yellowish. Disc of the hindwing dark reddish-yellow. Under surface lighter, the subapical and radial veins as far as the distal margin dirty ochreous-yellow, of the same colour are the veins on the hindwing; disc, base and distal margin are darker. Mexico to Colombia.

V. venosus Plötz (187 h) resembles *illudens*, but on the forewing it has a cellular and a submedian spot besides. Hindwing with a band of distinct spots. Beneath with distinct light yellow veins, between the veins there are yellowish antemarginal dots. Mexico to Brazil, Trinidad.

V. norma Dyar. Dark brown, costa of forewing and proximal margin in the basal half strewn with reddish-yellow, with 2 postdiscal, reddish-yellow dots and 2 more small subapical ones. Hindwing in the disc reddish-yellow. Beneath somewhat lighter, with reddish-yellow veins, on the hindwing with a postdiscal row of 4 reddish-yellow dots. Expanse of wings: 36 mm. British Guiana. It was bred from larvae living on water-plant (*Paspalum gracile*).

V. sacchariphila Dyar resembles *norma* above, but without any reddish-yellow at the costal and proximal margins of the forewing. Beneath the hindwing is light greyish-brown with 2 irregularly brown, black, bent lines in and behind the middle. Expanse of wings: 25 mm. British Guiana, bred on sugar-cane.

V. almoneus Schs. Above brown with a yellow cellular spot and a postdiscal row of spots. Hindwing like disc with a row of oblong, yellow postdiscal spots. Beneath brown, with light yellow veins, the spots of the hindwing more numerous than above and light yellow. Expanse of wings: 24 mm. Peru.

V. subplanus Kaye. Above deep dark brown with a yellowish spot behind the cell of the forewing and one below it farther towards the base. Beneath the same, the veins faintly lighter. The hindwing are still somewhat lighter, the veins scarcely lighter. Expanse of wings: 26 mm. Trinidad.

V. seriatus Mab. Black, with a reddish-yellow reflection. Forewing with 7 small, yellowish-white dots, below the margin rounded, then oblique; in the middle of the cell near the costal margin a dot, at the costal margin itself 2 similar streaks, fringes lighter. Forewing beneath blackish with the same dots, on the veins at the apex 5 or 6 yellow dots; the veins of the hindwing are striped light yellow, the anal part is strewn with yellow, with 2 indistinct yellow stripes; the cell is closed by a yellow streak; 6 small, postdiscal, yellow streak-shaped spots. Expanse of wings: 18 mm. Valera.

V. scheria Plötz (187 h) is a larger species the position of which is questionable. Above black. Beneath towards the margin on the forewing and almost on the whole hindwing steel-blue with fine white postdiscal and subapical dots. The submedian anal area of the forewing is very light, almost white. Brazil (Pará).

V. carasta Schs. Above brown, on the forewing postdiscally with a bent row of small yellow spots. Beneath brown, tinted violet, costa of forewing basally yellow, 2 yellow cellular spots, the postdiscal spots more distinct; on the margin there is a yellow line, between the veins distally convex and proximally connected with yellow streaks; the same line and internerval streaks also on the hindwing; proximal margin broad dark grey, strewn with yellow; in the cell and above it one yellow spot each as well as a postdiscal row. Expanse of wings: 24 mm. Petropolis.

V. chinta Schs. Dark brown with reddish-grey fringes. Forewing with small, yellowish-grey, indistinct spots, 3 postdiscal ones and 3 subapical ones. Hindwing haired lighter brown. Beneath brown with lighter veins; on the forewing the costal spots are lilac, the anal angle light. The hindwing shows an undulate, lilac postdiscal band not reaching to the broad, light brown inner-marginal part. Expanse of wings: 22 mm. Petropolis.

153. Genus: **Megistias** G. & S.

Antennae half as long as the costal margin; otherwise only distinguished from *Vehilius* by the different structure of the ♂ genitals.

M. tripunctatus Latr. (= *obsoleta* Mschlr.) (187 i) is above blackish-brown with faded, light spots, 2 postdiscal ones and 3 subapical ones. Beneath lighter, at the distal margin with a narrow dark line. Hindwing strewn with grey, in the disc with a row of blackish-brown spots, which is irregularly curved. Mexico to Brazil.

M. jera G. & S. (187 i) resembles *isus*, but it has a less pointed apex of the forewing, more indistinct spots and differently built genitals. Mexico (Guerrero).

M. labdacus G. & S. (187 i) looks above like *tripunctatus*. Beneath lighter, the hindwing strewn with grey, with a bent row of grey spots towards the costal angle. Mexico to Costa Rica and Venezuela, as well as Trinidad.

M. oebasus G. & S. is above monotonously blackish-brown, beneath the same, but somewhat lighter, the costal margin, apex, and the apex of the hindwing are marbled purple grey; fringes light, a little dark-speckled. Costa Rica.

M. edata Plötz (= *isus* G. & S.) (187 i). Above dark brown, with 3 small, white subapical dots and a postdiscal one behind the lower cell-angle. Beneath the hindwing as well as the anal part of the forewing are somewhat lighter violettish-grey, with a broad, straight, greyish-brown nebulous band from the costal angle of the hindwing to the middle of the proximal margin. Mexico to Guiana.

- catocala*. **M. catocala** H.-Schäff. (178 i) is larger, the ♀ shows 3 postdiscal spots, the submedian spot of which is yellowish, 3 subapical white dots and below them farther towards the margin 2 more small ones; fringes yellowish, speckled darker. Beneath the hindwing is violettish-grey with irregular darker macular bands at the base, in the disc and before the margin, the latter being deposited above the cell. Patria unknown. PLOETZ's figure entirely resembles that of *Halotus saxula* (= angellus, 183 c).
- theogenis*. **M. theogenis** Cap. (187 i) entirely resembles *tripunctatus* above, blackish-brown with 3 small, white subapical and 2 postdiscal spots. Beneath much lighter brownish-grey, in the disc of the forewing blackish, in the submedian area lighter whitish. Hindwing with whitish dots in the cell and behind it in a bent row.
- tripunctus*. **M. tripunctus** H.-Schäff. (= ancus Mschr., ? conta Plötz?) (187 k) is above somewhat like *theogenis*, but it has only two subapical dots and besides another small yellowish submedian spot; fringes of hindwing somewhat yellowish. Beneath likewise allied to the preceding, on the hindwing with a blurred cellular spot and a lighter grey postdiscal band. South America, Cuba.
- uruba*. **M. uruba** Plötz (187 k). Above brownish-black with entirely extinct, small subapical spots, below them 2 spots removed more towards the margin, and 2 postdiscal spots. Beneath of a somewhat lighter and brownish tint, on the forewing with larger spots, the anal part broadly lighter grey. The hindwing is broadly hued purple-brown at the costal margin, in the larger anal half violettish-grey with 2 bands of purple-brown spots obliquely extending from the apex to the proximal margin and not crossing the inner-marginal fold. Brazil.
- fraus*. **M. fraus** G. & S. (187 i). Lustrous blackish-brown, with 3 white hyaline subapical dots. Beneath lighter, the forewing marbled darker, with a quadrangular, blackish-brown subapical macula. Hindwing with 3 dark bands. Mexico, Guatemala, Honduras.
- telata*. **M. telata** H.-Schäff. (= tyrtaeus Plötz) (187 i). Above like *fraus*, but besides with 2 postdiscal spots and 2 often indistinct, dirty white, small spots in the middle of the costal margin. Beneath blackish-brown, the spots larger, the costal margin ferruginous-brown, the distal margin grey. Hindwing ferruginous-brown with 2 irregular bands from the proximal margin to the costal margin and apex. Mexico to Venezuela and Guiana.
- corticea*. **M. corticea** Plötz (= epiberus Mab.) (187 k). Above blackish-brown with an oblique row of ochreous-yellow spots; hindwing almost entirely scaled and haired ochreous-yellow. Beneath ferruginous-brown or ochreous-yellow, forewing in the proximal half blackish with 2 yellow discal spots. Mexico to Brazil and Trinidad.
- noctis*. — f. **noctis** Plötz is above and especially beneath very much darkened. From the Chiriqui. — f. **lysias** Plötz
lysias. is a transition to it from Venezuela.
- leucone*. **M. leucone** G. & S. (187 k) is similar, somewhat smaller, the forewing with only 2 postdiscal spots and 2 subapical ones; hindwing less ochreous-yellow. Beneath likewise darker. Guatemala.
- corius*. **M. corius** Schs. (187 k). Dark brown, fringes distally grey; the forewing shows small postdiscal accumulations of minute yellow scales between the veins. Beneath the forewing is black, at the costal margin and apex strewn somewhat ochreous, with a whitish subapical band. Hindwing lilac-grey, strewn with whitish, in the basal half of the costal margin and a broad shade from the middle of the proximal margin to the apex dark brown, strewn with ochreous. Allied with *telata*. Expanse of wings: 21 mm. Castro (Paraná).
- xantho*. **M. xantho** Schs. (189 h). The blackish-brown forewing shows a yellowish-brown costal-marginal stripe in the basal half and a similar one above the inner-marginal vein and small postdiscal spots scaled yellowish, the hindwing exhibiting a similar postdiscal shade. The light brown fringes are more or less spotted black. Beneath the veins in the costal-marginal and distal-marginal half are striped yellowish, the spots similar as above. Hindwing more lilac-grey, with yellowish veins, with a bent, dark discal band and large marginal spots. Costa Rica (Juan Vinas).
- ranesus*. **M. ranesus** Schs. Above plain dark brown, with lighter fringes. Forewing beneath dark brown, at the proximal margin lighter, at the distal margin and apex strewn with lilac, at the base of the costal margin and before the apex mixed somewhat with ochreous. Hindwing in the costal half reddish-brown with an ochreous-red basal spot, in the distal half brown, strewn with lilac; lilac scales towards the base below the cell. Expanse of wings: 20 to 24 mm. Castro (Paraná).
- polistion*. **M. polistion** Schs. Dark brown, fringes reddish-grey. Forewing with 2 small, whitish postdiscal spots, at the base of the costal margin scaled olive; subapically and above the middle of the submedian accumulations of yellowish scales. Beneath light olive-brown, disc of forewing blackish, with a postdiscal row of small yellow-reddish spots and a similar cellular spot. Expanse of wings: 27 mm. Petropolis.
- erythrosticta*. **M. erythrosticta** Plötz (187 k). Above purple-brown with a small cellular spot and 2 small postdiscal spots, and a subapical dot; fringes grey, speckled darker. Beneath lilac-grey, disc of forewing darkened with purple. Hindwing lilac-grey, strewn with ash-grey, with indistinct purple macular bands in the middle and before the distal margin, as well as a darkened base. Rio de Janeiro.
- servilius*. **M. servilius** Plötz (187 k). It is questionable whether the species is correctly placed here. Above black with 2 white postdiscal spots and a small submedian one. Beneath light brown, with finely darker veins and a whitish stripe along the lower median vein of the hindwing. From Surinam.

M. fimbriata Plötz (187 f). Its position here is just as questionable. Easily recognizable by its orange-red head and palpi, and orange fringes. It is much larger than *Mastor bellus* (187 h) and is easily discernible from it by the absence of the stigma and the entirely red head. Mexico. *fimbriata*

M. monestes Schs. (188 a). On the dark brown forewing there is a very indistinct postdiscal row of small, greyish-brown spots. Beneath dark grey with blackish-brown markings: 2 oblong spots behind the cell and 2 oblong marginal spots analwards and 2 subapical dots. Hindwing with a dark discal shade, the darkest above the cell, traversed by the veins, close behind the cell there is a row of dark spots, behind them a light brown shade; in the brown distal margin there are small, grey antemarginal spots. Expanse of wings: 28 mm. Novo Friburgo. *monestes*.

M. miaba Schs. from an unknown habitat is above dark brown with grey fringes; forewing with 2 minute postdiscal dots and a subapical one. Beneath the forewing is blackish in the cell and at the proximal margin, the costal margin, apex and distal margin is light brown with yellowish veins, beside the small spots of the upper surface with a light anal-angular spot; the light brown hindwing has yellow veins with a white dot at the cell-end, and a series of white dots behind it. Expanse of wings: 29 mm. *miaba*.

M. distigma Plötz (= *chula* Schs.) (188 a) is above brown with grey fringes and greenish tinted veins, with 2 white, hyaline postdiscal spots and a yellow one above the middle of the submedian. Hindwing at the costal margin dusted with violet. Beneath dark brown, at the costal margin reddish-brown, the distal margin lilac, the spots as above. Hindwing lilac-grey, at the costal margin broad violet, at the proximal margin reddish-grey with a round white spot at the cell-end and a bent row of indistinct, small, whitish postdiscal spots. Expanse of wings: 27 mm. Petropolis. *distigma*.

M. vanilia Schs. Above uni-coloured dark brown. Beneath light violettish-brown, at the costal margin greenish and at the proximal margin broadly greyish-black with a lighter anal-angular spot; a subapical yellow dot. Hindwing at the proximal margin thickly strewn with yellow and a yellow dot at the cell-end and small yellow postdiscal dots. Expanse of wings: 28 mm. Petropolis. *vanilia*.

M. gispara Schs. Dark brown with grey fringes and a postdiscal row of small, indistinct, grey spots; at the costal margin and apex scantily strewn with ochreous; the hindwing is haired somewhat lighter brown. Beneath light brown, dusted ochreous-yellow, at the proximal margin of the forewing broadly blackish, the hindwing with a black dot behind the lower cell-angle and one above it, behind both with a bent lighter patch. Expanse of wings: 29 mm. Petropolis. *gispara*.

M. vorgia Schs. (188 a). Above dark brown with grey fringes with 2 small white hyaline postdiscal spots and 3 minute subapical ones. Beneath the forewing is blackish in the cell and at the proximal margin, at the costal margin, apex and distal margin light reddish-brown; veins and small internerval stripes yellowish. Hindwing reddish-brown, with yellow veins and small, indistinct grey internerval stripes, and 4 small whitish postdiscal spots. Expanse of wings: 28 mm. Castro (Paraná). *vorgia*.

M. chao Mab. belongs hereto. Above coppery yellowish-brown; forewing with 3 blurred, small apical spots and in the disc behind the cell 2 or 3 small transparent spots; fringes dirty yellow. Forewing beneath yellowish with a reddish costal margin; basal half blackish, only the 2 lower spots are visible on the margin of the black. Hindwing yellowish with a greenish lustre. Bolivia. *chao*.

M. xenos Mab. is somewhat smaller than *chao*. Above dark brown; forewing with 3 hardly visible apical dots and 2 minute yellowish dots behind the cell; costal margin along the cell yellow. Hindwing in the middle of the margin light yellowish. Forewing beneath grey with a lilac lustre, in the proximal half dull blackish, the punctiform spots more distinct; in the cell there are grey clouds. Hindwing ash-grey with a reddish or lilac lustre, strewn with white, with white veins; a postdiscal row of small grey scale-spots with a pink lustre. Before the greyish-white fringes there is a black line on both sides bordered with white. Bolivia. *xenos*.

M. sulla Plötz (188 a). Above black with 3 subapical and 3 postdiscal whitish spots. Beneath light grey, in the disc of the forewing black, on the hindwing with some fine black dots in and behind the middle. Colombia. *sulla*.

M. arcas sp. nov. (188 a) is above dark brown with 3 postdiscal and 3 subapical, small, hardly lighter spots on the forewing. Beneath duller brown, on the forewing the small lighter spots are a little more prominent owing to their being slightly surrounded by dark. Hindwing in the basal two thirds a little darker than at the margin, in this marginal area near the margin of the darker discal area there are 4 or 5 small, darker eye-spots. Rio Songo (Bolivia). *arcas*.

M. argus sp. nov. (188 a) beneath somewhat resembles *Cobalus argus* (186 a). Above uni-coloured brown, beneath lighter; behind the cell of the hindwing there are, between the somewhat lighter veins, 5 dark spots distally bordered by somewhat lighter spots; that between the radial veins is the largest and quadrangular, and lies directly behind the lighter transverse vein before which there is yet a blackish transverse streak in the cell. From Matagang (Upper Cauca Valley). *argus*.

M. sancoga Schs. Forewing above dark brown with an oblique dark shade from the lower median vein to the apex. Beneath brown, dusted with ochreous; hindwing with a small brown postcellular dot and a very indistinct brownish postdiscal shade. Expanse of wings: 30 mm. Petropolis. *sancoga*.

- a.* **M. carinna** Schs. Wings dark brown with more reddish fringes. Forewing at the cell-end somewhat darkened. Beneath the forewing is violettish-brown, the distal margin dusted with lilac, with a light brown anal-angular spot; hindwing the same with a bent postdiscal row of small, lilac-white spots. Expanse of wings: 23 mm. Castro (Paraná).
- jamaca.* **M. jamaca** Schs. is above dark brown, basally haired somewhat ochreous, with a small, semi-diaphanous postdiscal spot and 3 small subapical ones. Beneath lighter, only the cell and proximal margin of the forewing darker, hindwing with a postdiscal row of small grey spots. Expanse of wings: 31 mm. Jamaica.
- corescene.* **M. corescene** Schs. Dark brown with 3 subapical and 2 postdiscal small hyaline spots. Beneath brown, forewing at the distal margin lilac, the broadest at the middle radial vein. Hindwing dusted with lilac except the apex and a bent brown discal shade and some small antemarginal spots. Expanse of wings: 24 mm. Castro (Paraná).
- mendica.* **M. mendica** Mab. is above blackish-brown with a reddish lustre in the marginal area of the forewing, the basal half is blackish as far as the cell-end, here bordered by an undulate line and indistinct yellowish clouds. Hindwing in the proximal part somewhat ferruginous-brownish. Beneath reddish-brown, the basal part of the forewing blackish, the small yellowish clouds clearer than 7 small spots. Hindwing reddish-brown with a bent demi-band through the disc. The ♀ is darker, otherwise similar. Bolivia.

154. Genus: **Parphorus** G. u. S.

Distinguished from *Megistias* by its bare middle tibiae, more slender body and a thick stigma in the ♂, extending from the rise of the upper median vein to the submedian, filling up the angle of the base of the lower median vein, and bordered by a stripe of velvety-black scales.

- storax.* **P. storax** Mab. (188 a). Blackish-brown, behind the stigma haired ochreous-yellow in the shape of 3 small spots. Beneath lighter, at the costal margin and apex of the forewing, and on the hindwing with yellow veins. Panama to Colombia, Venezuela and Guiana. Trinidad.

155. Genus: **Vorates** G. & S.

Distinguished from the preceding genus by the different structure of the genitals and the scent-spot of the ♂ consisting in a long scent-scale stripe on the middle of the median and a shorter longitudinal stripe.

- decorus.* **V. decorus** G. & S. (= *tanaquilus* Mschlr.?, *saturnus* F.?) (188 b). Blackish brown, with a darker stigma and 3 ochreous-yellow spots behind and below the cell, and a minute subapical dot. Beneath the same, but the inner-marginal spot is absent; costal margin, subcostal and radial veins as well as the hindwing veined yellow. Mexico to Brazil.
- godmani.* **V. godmani** sp. nov. entirely resembles the preceding, but the stigma is larger, and shaped as in *Phlebodes tiberius* (187 a). South America?
- sapala.* **V. sapala** G. & S. (188 b) is likewise very closely allied, but the stigma is longer and below its upper part there is an oblong hyaline spot. Hindwing above more olive ochreous. Beneath as *decorus*. Panama.
- auristriga.* **V. auristriga** sp. nov. (188 b) is very well distinguished by the very long, narrow, orange stripe below the median with a continuation behind the upper median vein and a sagittiform subapical spot. Hindwing in the disc, as well as the forewing at the costal margin and submedianly with a somewhat ferruginous reflection. Beneath like *decorus*, but with bright orange veins. Described according to 1 ♂ from the Songo (Bolivia) from the Coll. FASSL.
- cotiso.* **V. cotiso** Schs. (189 i). Above dark brown, costal margin as far as the middle olive, striped the same above and below the inner-marginal vein; below the median between the veins striped yellow, a small spot distally above it, with a yellow subcostal dot. Disc of hindwing of a bright brown. Beneath as above, but the veins in the marginal area striped yellow, on the hindwing in their whole length. Costa Rica (San Mateo).

156. Genus: **Pheraeus** G. u. S.

Antennae somewhat longer than in the preceding genera, with a long and fine apex of the club. The ♂ stigma is angular, thick, situate between the middle part of the median and the rise of the lower median vein. Only one species:

- epidius.* **Ph. epidius** Mab. (188 b) is very well distinguished by a long, yellow submedian stripe of the forewing; the hindwing is almost entirely reddish-yellow, with a darker margin. Hindwing beneath in the basal two thirds yellow like the body beneath. Nicaragua, Panama.

157. Genus: **Molo** G. & S.

Apex of forewing more prolonged than in the affinities. Middle tibiae covered with few short spines. The ♂ has no scent-organ.

M. heraea *Hew.* (= *xenarchus* *Mab.*) (188 b) is above blackish-brown, in the basal half of the costal margin and in the cell, on two thirds of the proximal margin, in 4 postdiscal spots growing smaller towards the apex, and a bipartite subapical spot lustrous orange. Hindwing orange, the costal margin broad, the proximal margin narrow, and a shortened basal line below the cell blackish-brown. Beneath yellow, marked red-brown, forewing with an irregular median band from the base to the apex; proximal margin and anal angle are blackish, the hindwing at the proximal margin blackish-brown. Panama to Guiana and the Amazon District. In fresh specimens the hindwing is iridescent. *heraea.*

M. nebrophone *Schs.* (189 f) resembles *heraea* above; the orange colour is browner, in the cell there is a blackish-brown stripe-spot; the black costal margin of the forewing exhibits in the middle a projection towards the cell, the proximal margin is broader black. The hindwing is distally reddish with yellow postdiscal spots and a blackish-brown shade behind the cell. The ♀ is predominantly blackish-brown with smaller yellow spots. Costa Rica, Panama. *nebrophone.*

M. kenava *Btlr.* (= *myrona* *Plötz*) (188 b). Blackish-brown, at the proximal margin of the forewing red-brown, with an orange, oblique postdiscal band and a separate subapical spot. Hindwing in the disc reddish-yellow. Beneath yellow, the lower half of the cell, the proximal margin and anal angle black. Hindwing yellow speckled with red, with a small red-brown discal spot and a black proximal margin. Described from Venezuela. *kenava.*

M. humeralis *Mab.* (188 c) differs from *heraea* by its larger size and much more extensively blackish-brown colour, the cell containing only a small yellow dot at its upper end. Hindwing black with a broad, straight, orange transverse band. Beneath red-brown with postdiscal bands of yellow spots on both wings, at the proximal margin of the forewing black, at the costal margin of the hindwing dusted greenish. The ♀ is very much more extensively blackish-brown. Brazil, Colombia. *humeralis.*

M. apella *Schs.* almost exactly resembles *humeralis* above. Hindwing beneath brownish-yellow with black marginal dots; by darker antemedian and postmedian shading an orange postdiscal band is distinctly prominent; also before the margin is dark shading; the veins are somewhat lighter. In the ♀ the ground-colour beneath is darker olive-brown. Expanse of wings: 37 to 45 mm. Costa Rica (Carillo). *apella.*

M. misius *Mab.* Jet-black, costal margin of forewing at the base reddish-yellow, two such spots at the cell-end, behind them a macular band from the apex to the submedian, from here as a broad stripe to the base. Hindwing black with a short, bent discal band, also the proximal margin being reddish-yellow. Fringes of forewing reddish-yellow speckled with black. Fringes of hindwing plainly reddish-yellow, not speckled. Forewing beneath more yellow, at the costal margin as far as the apex reddish-yellow, at the base and the proximal angle black. Hindwing yellow, with long, black streak-shaped spots between the veins, at the costal margin bordered with black, at the proximal margin black with a yellow longitudinal stripe on the fold; below the costal margin there are 3 small black strigiform spots. Expanse of wings: 27 mm. Massauary. *misius.*

158. Genus: **Vinius** *G. & S.*

Chiefly distinguished by the ♂ stigma on the forewing: a scent-stripe on the lower median vein, another one below it. The hindwing near the base of the proximal margin shows a tuft of whitish hair.

V. sagitta *Mab.* (188 c) is very similar to *M. heraea* (188 b) but smaller, the yellow is darker, less bright orange, the blackish-brown colour broader, the hindwing broadly bordered with blackish-brown. Beneath the same, but paler yellow, the hindwing with dispersed, oblong, brown spots. Panama. *sagitta.*

V. arginote *G. & S.* (188 c) is very much like the preceding, more reddish-yellow and more extensively so especially in the disc of the hindwing. Hindwing beneath with rounded, not oblong submarginal spots. Amazon, Brazil. *arginote.*

V. exilis *Plötz* (188 d) is above blackish-brown, in the cell reddish-yellow like an oblique band to the apex extending at the proximal margin to the base, and a postdiscal costal-marginal spot. Hindwing only in the basal third black with a roundish yellow cellular spot, behind it bright orange with a narrow black border. Beneath the light yellow hindwing exhibits a larger black cellular spot and no postdiscal nor antemarginal punctiform spots. The habitat stated, California, is wrong. Patria unknown. Perhaps identical with *ephesus* *Hbn.* which originates from Surinam. *exilis.*

V. nicomedes *Mab.* (= *letis* *Plötz*) (188 d) is very much like *arginote* above, but the hindwing beneath is without the blackish spots. From Brazil (Rio de Janeiro, Manaos). *nicomedes.*

V. ephesus *Hbn.* (188 c) is smaller, lighter yellow, especially the whole costal-marginal part broadly yellow; also at the proximal margin near the base a yellow, oblong spot. Hindwing in the disc yellow with a but narrow black margin. Guiana. *ephesus.*

159. Genus: **Synale** *Mab.*

Antennae and palpi like in the following genera. Forewing with a rounded apex; the bent costal is nearer the uppermost subcostal vein; the uppermost median vein rises before the cell-end. Posterior tibiae grey-haired.

hylaspes. **S. hylaspes** Cr. (188 d). Above black with 2 large white discal spots and a broad subapical band of the forewing, and a roundish spot near the apex of the hindwing. In the ♀ the spots are longer and narrower, and besides there is a submedian spot and a small postdiscal spot. Beneath the hindwing shows a long longitudinal ray from the base to the middle of the distal margin, proximally more orange, distally lighter yellow. Brazil (Pará).

silanion. **S. silanion** Plötz (188 d) is very similar, somewhat smaller. The hindwing exhibits a longitudinal ray being above shorter, beneath extending from the base to the middle of the distal margin, and being interrupted at the cell-end. Fringes white. From Bahia.

160. Genus: **Paracarystus** G. & S.

Different from *Carystus* by another ♂ genital organ, the strongly prolonged valves being bent. Middle tibiae spined.

hypargyra. **P. hypargyra** H.-Schüff. (= *argyris* Mab., senex Plötz) (188 e). Above blackish-brown with a white cellular spot, 3 postdiscal and 3 small subapical spots. Fringes especially on the hindwing ochreous. Beneath the same, but duller brown, at the apex of the forewing lighter. Hindwing beneath variably violettish-blue or light steel-blue, with dark brown veins. Fringes whitish. Brazil (Rio de Janeiro, Bahia).

radiatus. **P. radiatus** Mab. It is questionable whether it belongs hereto. Above blackish-brown, with 3 yellowish hyaline spots: one in the cell and 2 quadrangular ones behind it and below it, the latter being larger. Forewing without spots with a somewhat indented margin. The forewing is beneath similar, at the costal margin and apex lighter; hindwing blackish with broad white veins, along the upper edge of the cell, on the upper radial vein and the subcostal vein with a broad white band forking towards the margin like a Y and being below shaded with red-brown. Fringes reddish-white. Expanse of wings: 39 mm. Brazil (Sao Paulo).

menetriesii. **P. menetriesii** Latr. (= *rona* Hew.) (188 d, e) is most variable in its size and the number of the white spots. Above blackish-brown with or without 1 or 2 cellular spots and 2 or 3 postdiscal ones. Beneath the apex of the forewing and the whole hindwing are dull metallic violettish-blue, in the ♀ more greenish-blue, with 2 brown, narrow transverse bands. Fringes dark brown. From Colombia and Brazil.

koza. **P. koza** Btlr. (188 e) is above similar, intensely spotted white on the forewing. Beneath on the forewing a large, subapical, blue spot, hindwing light metallic blue, in the discal area yellowish iridescent, with a brown, bent transverse band from the apex almost to the middle of the proximal margin. Brazil.

161. Genus: **Zenida** Mab.

Antennae long and slender with a fusiform club; second palpal joint rising, projecting beyond the eyes, the conical last joint hidden in the hair of the 2nd joint. Apex of forewing obtuse. Femora clad with thick short hair. The ♂ shows a very conspicuous scent-organ: a silvery hair-scale stripe begins pointed at the rise of the upper median vein and grows broader, filling up the angle of the rise of the lower branch and extending to the base of the median.

abdon. **Z. abdon** Plötz (188 f) is a large, above monotonously blackish-brown species with a grey scent-stripe. Beneath the apex of the forewing and the whole hindwing are dark slate-coloured blue, with brown veins. From Brazil.

162. Genus: **Cyclosma** gen. nov.

Distinguished from the preceding genus by a somewhat longer, conical and obliquely rising terminal joint of the palp. On the forewing the upper median vein rises close at the cell-end; below its proximal third there is a circular, black, convex scent-spot corresponding to a slight depression on the under surface; in the lower cell-end there is a thinly scaled part.

abdonides. **C. abdonides** sp. nov. (188 f). Above uni-coloured blackishbrown, the scent-spot black, the thinly scaled part in the lower cell-angle is yellowish. Ends of fringes lighter, tinted ochreous, at the anal angle of the hindwing almost white. Beneath dull greenish slate-coloured, with black veins, below the cell of the forewing and from there in the shape of a bow to the anal angle blackish, before it in the submedian area whitish. Anal margin of hindwing brownish. According to 1 ♂ from the Songo (Bolivia).

163. Genus: **Carystus** Hbn.

Antennae long, with a long club and a long reverted apex; last joint of the palp short. Cell of forewing of two thirds of the length of the costal margin. ♂ without a scent-organ.

claudianus. **C. claudianus** Latr. (188 e). Above blackish-brown with 2 large white cellular spots, one between the median veins and a smaller one behind it; a subapical band of 4 lilac-white spots. Hindwing with a large,

rounded white postcellular spot. Beneath spotted the same, two thirds of the costal margin and the apex are lilac-grey, as well as the hindwing in the costal-marginal part, behind the cell and at the distal margin, with black veins; fringes of hindwing analwards and the abdomen beneath white. Guatemala to Bolivia.

C. diores Plötz (188 e) resembles the preceding above, but the hindwing is beneath marked just like *diores*. above. South America?

C. phorcus Cr. (188 f) entirely resembles *Vettius marpesia* (189 d) above and beneath, but it is larger *phorcus*. and distinguished by the absence of the scent-scale spot. Above the white band of the hindwing is longer and extends almost to the proximal margin, and the fringes are in their whole extent yellowish-white, too. Surinam.

C. ambrosei Weeks is above black with a white subapical dot of the forewing, below it there is a post- *ambrosei*. discal row of 5 spots to the middle of the proximal margin; the two uppermost spots are very small, the next is very large, the next small, and the lowest very small. Hindwing with a broad white band from the middle of the proximal margin to the cell-end; the proximal margin is grey-haired. Beneath more brownish, the spots closer together; on the hindwing the band being yellowish-white here extends from the middle of the proximal margin in the same width to the apex. Expanse of wings: 1.1 inch. Venezuela (Suapure).

C. richardi Weeks. Forewing above dark brown with 2 small, white subapical dots and 4 postdiscal *richardi*. spots, of which that below the median is the largest, the two upper ones being small. Hindwing brown with a whitish patch near the base. Beneath as above, forewing submedianly very much strewn with white; hindwing dark brown, the basal area except the brown costal margin yellowish-white. Expanse of wings: 1.3 inch. Venezuela (Suapure). It may perhaps be better to place it to *Vettius* (p. 981).

C. jolus Cr. (188 f). Above blackish-brown with 2 cellular spots 5 postdiscal and 2 subapical white *jolus*. spots. Hindwing with a cellular spot and an oblong diffuse patch behind it. Beneath the apex of the forewing, and the hindwing are golden yellow, with chestnut-coloured veins, with the white spots of the upper surface and golden yellow spots at the costal margin and subapically on the forewing. Surinam.

C. bursa Hew. (188 f) is not dissimilar, but the hindwing above shows a large, round discal spot. Be- *bursa*. neath the apex of the forewing is not yellow but black, but the inner-marginal part is broad whitish. The yellow hindwing shows a broad white longitudinal patch through the cell from the base to the distal margin, distally dusted with a bluish grey as is also a wedge-shaped spot below it; the cellular spaces at the distal margin are partly filled up by brownish wedge-shaped spots; the veins are not so red-brown. Brazil (Pará).

C. subviridis Plötz (188 g). It is questionable whether this large, beautiful species belongs hereto. *subviridis*. Above jet-black with an oblique row of 4 postmedian, white spots, the lowest being very small, that above it the largest, quadrangular; 2 subapical white dots; fringes of hindwings somewhat lighter, more grey. Beneath the costal margin and the apical half of the forewing is of a deep green with fine yellowish veins. The hindwing is coloured the same, with a somewhat lighter postdiscal band and a blackish inner-marginal wedge. São Paulo.

C. cynaxa Hew. (188 g) is above black, suffused with steel-blue, with a white, blue iridescent discal *cynaxa*. band of the forewing. Beneath duller black, apex of the forewing and hindwing grey, especially the latter thickly strewn with a yellowish-green and with black veins. Eyes red. Mexico to Panama.

C. pieris sp. nov. (188 g). Above blackish-brown with a broad, silvery white, semi-transparent discal *pieris*. oblique band of the forewing composed of 3 spots, 2 small postdiscal ones behind them and 3 subapical ones, the lowest of which is situate more towards the margin. Beneath the apex of the forewing is reddish-brown, the hindwing with deep chestnut-brown veins on a blackish-brown ground, with a very broad silvery band of long, wedge-shaped spots, running through the cell and reaching neither to the costal margin nor to the proximal margin. 1 ♂ from the Rio Songo (Bolivia), type in the Coll. FASSL.

C. ebusa Cr. (= *psecas* Cr., *belistida* Hew.) (188 g). Forewing blackish-brown, hindwing almost *ebusa*. entirely white, only the broad costal margin and distal margin brown. Beneath lighter, the apex steel-grey, costal margin ferruginous brown, with some white postdiscal spots towards the apex. Hindwing white, veins and a cellular spot chestnut-brown, the distal margin towards the apex irregularly marked chestnut-brown and steel-grey; anal angle blackish-brown. Panama to the Amazon and Bolivia.

C. antenora Ehrm., described as *Pamphila*, may presumably be ranged here. Above dark brown, *antenora*. with a reniform hyaline spot in the cell, a large, quadrangular one touching it beneath, above it a triangular one, its apex directed distally, above it more distally a grey streak-spot. Beneath somewhat lighter, the forewing apically tinted lilac, marked the same. Hindwing entirely white with a pinkish-reddish lustre. Expanse of wings: 42 mm. Venezuela (Suapure).

C. marcus F. (= *lyrcea* Plötz) (188 g). Above black with a small white cellular spot, 3 postdiscal *marcus*. spots and 2 subapical ones, hindwing with a broad, white transverse band which, being widened, almost reaches to the proximal margin. Hindwing yellowish, in the disc more white with a brown longitudinal stripe above the cell to the distal margin, a shorter one below it, and a large black anal spot. Brazil (Bahia, Pará), Panama to Guiana, and Trinidad.

C. aurelius Plötz (188 h) is very much like *marcus*, the white discal spot of the hindwing extends *aurelius*. to the anal angle; beneath the inner-marginal part is white, not blackish-brown. Nicaragua to Colombia, Venezuela and Brazil.

- diversus.* **C. diversus** H.-Schäff. (= maeon Mab.) (188 h) is also very similar, but the hindwing has beneath blackish-brown veins. Nicaragua to Brazil.
- fantasos.* **C. fantasos** Cr. (= abebalus Cr., eucherus Plötz) (188 h). Above blackish-brown with 3 postdiscal and 2 or 3 subapical creamy spots, hindwing with a similar discal band. Beneath the forewing has a reddish-brown apex, the hindwing is Isabel-coloured, with red-brown veins, a chestnut-brown spot at the cell-end and a larger one behind and below the lighter discal band; anal angle blackish. Mexico to Brazil. The green larva lives on grasses such as *Panicum ramosum*.
- ploetzii.* **C. ploetzii** Capr. (188 h) is above black, at the proximal margin of the forewing with olive hair, with 2 yellowish-white, quadrangular postdiscal spots and 3 small subapical ones. Hindwing in the disc light olive. Beneath on the forewing the costal margin and apex are chestnut-coloured, the spots as above. Hindwing reddish-yellow, with chestnut-brown veins, at the base except the costal margin, in the apical half of the distal margin and at the proximal margin chestnut-brown, from the base to the anal angle extends a black wedge-shaped spot being here very broad. From Brazil.
- clavicula.* **C. clavicula** Plötz (= furcifer Mab.) (188 i). Brown, the forewing with 3 white subapical dots and 2 postdiscal spots, below them a third disappearing in a whitish brightening which extends to the thorax. Hindwing with a light reddish-yellow band of 4 oblong spots. Forewing beneath blackish, the apex tinted light yellow, with black veins and black internerval stripes. Hindwing light yellow with black veins which, except the lower median vein, are forked at the margin; at the cell-end a black arcuate stripe. From Brazil.
- lucretius.* **C. lucretius** Latr. Above brown with 3 postdiscal spots and an ochreous-yellow anteterminal band on the hindwing; beneath the hindwing is blackish-brown with a white costal-marginal spot near the base and an oblique, olive-yellow band from the apex to the proximal angle, which below the cell sends forth a white continuation to the proximal margin. Brazil.
- abaris.* **C. abaris** Mab. is above black, on the forewing with 3 apical hyaline dots and 3 postdiscal spots behind and below the cell-end. The hindwing is in the disc dusted with ferruginous brownish. Beneath the forewing is black, in the apical part lilac with 3 black, small sagittiform spots between the hyaline dots. The hindwing is blackish, in the basal part and at the costal margin lilac-white with a black cellular spot and 2 smaller black apical spots behind the cell. Fringes grey. Expanse of wings: 28 mm. Porto Cabello.
- arva.* **C. arva** Hew. must be allied to the preceding; the description, however, of this species has not been accessible to us.
- micon.* **C. micon** Mab. is likewise similar to *abaris*, but much larger. Deep blackish-brown with 2 longish, yellow apical hyaline dots; in the cell-end are 2 streak-spots above each other, behind them there are 3 more, the lowest being diffuse, reddish-yellow, the uppermost very large, oblong quadrangular; the base of the costal margin is yellow. The hindwing shows 2 small postcellular spots. Beneath the forewing is blackish, at the costal margin and apex reddish, the hindwing reddish-brown with the 2 dots of the upper surface, besides one in the cell and one more towards the apex. Expanse of wings: 34 mm. Brazil.
- artona.* **C. artona** Hew. (188 i). Blackish-brown with 2 white cellular spots, 3 postdiscal and 3 small subapical spots; the hindwing shows 4 white spots in a bent row. Beneath the forewing is lighter, the apex grey; the hindwing is purple-grey with whitish-grey veins, costal part and proximal margin as well as internerval stripes; behind the cell are 5 whitish spots in a bent row. Nicaragua to Brazil.
- bebarus.* **C. bebarus** Plötz (188 i) is similar, smaller; the forewing is without the cellular spots; the small spots of the hindwing are minute and insignificant, of a yellowish tint. Beneath browner, with light yellowish veins and small, yellowish, postdiscal punctiform spots. Colombia.
- coryna.* **C. coryna** Hew. (= catargyra Fldr.) (188 i) is easily discernible by the hindwing being silvery beneath with 2 red-brown longitudinal stripes. Mexico to Bolivia.
- superbiens.* **C. superbiens** Mab. is black, the forewing with 2 white hyaline spots: 3 subapical ones, 4 postdiscal ones in an oblique row and 2 oblong cellular spots, the base striped yellow. Hindwing with a white, bipartite hyaline stripe through the cell; inner-marginal fold strewn with white. Forewing beneath as above, at the costal margin yellow, proximal margin white; at the margin are yellow spots between the veins. On the hindwing the median area round the hyaline stripes is blackish, between the veins striped yellow. Head with 4 white dots. Expanse of wings: 52 mm. São Paulo.
- dion.* **C. dion** Plötz (= diana Plötz i. l.) (189 a) is not unlike *fantasos* above, but the ground-colour is more olive-black, not brown, at the costal margin of the forewing and proximal margin of the hindwing dusted with whitish. Fringes white, blackish on the ends of the veins. Beneath the forewing is the same, but at the distal margin grey in the lower half. Hindwing yellowish-white with a large, oblong cellular spot, above it in the cell clouded grey with a broad, olive grey nebulous band in the middle of the distal margin. São Paulo.
- seitzii.* **C. seitzii** sp. nov. (189 a) is very similar, above browner, the subapical dots almost extinct, on the hindwing there is on the contrary a very much broader, coherent postdiscal band extending to the grey, densely white-haired inner-marginal part. Shape of wings longer, anal angle of the hindwing very much extended. Beneath the forewing is as in *dion*, the hindwing purely white with a brown, ferruginous-haired costal-marginal

spot near the base; beneath and comprising the cell like a bow, there is a large, irregular spot, in the upper proximal part which with a tooth extends into the middle of the cell, it is black strewn with light blue scales, distally and beneath olive-brown, strewn with ferruginous; at the distal margin, between the radial veins, there is a similar, olive-brown spot, between and below the median veins there are 3 extinct, small, grey nebulous spots before the margin. South Brazil (Sa. Cruz) in the Coll. SEITZ.

C. subrufescens Schs. (189 i) is above dark brown with a reddish base of the costal margin of the forewing and yellowish-white hyaline spots: 1 stripe in the cell-end and a spot below it; 3 postdiscal spots, the two lower ones small, and 2 subapical spots; fringes at the proximal angle yellowish. Beneath black, costal margin, apex and margin of forewing reddish-brown, hindwing likewise brownish-red with fine yellow veins. Expanse of wings: 36 mm. Costa Rica. *subrufescens.*

164. Genus: **Zenis** G. & S.

Wings narrower than in *Carystus*, distal margin of forewing concave; the lower median vein rises close at the base, the upper one at the lower cell-angle. The ♂ does not exhibit a stigma, but a hair-pencil below the lower median vein of the hindwing.

Z. minos Latr. (= jebus Plötz, melaleuca Plötz) (189 a). Above blackish-brown with a large, white hyaline spot in the lower cell-end and below it, as well as 4 or 5 small subapical spots in a broken row. The hindwing shows a short, narrow, white median band. Beneath somewhat lighter, more reddish, with a straight, white, at the edges ochreous-brown transverse band from the apex to the middle of the proximal margin, before it interrupted. Mexico to Brazil. *minos.*

Z. calvina Hew. is above black with a narrow white cellular spot and a large, quadrangular one below it, as well as 4 subapical ones in a row. Hindwing with a roundish discal spot. Beneath the same, but the hindwing is tinted deep red-brown. — In f. **dissoluta** Plötz (189 b) there is besides a large, white submedian spot on the forewing. Bahia; Pará. *calvina.*

Z. ozota Btlr. (189 a) is above hardly discernible from the preceding, but the spot of the hindwing ends towards the apex somewhat more pointed and is somewhat strewn with brownish, especially at the margins and on the veins. Beneath as above, but the hindwing shows a yellowish, broad transverse band from the apex to the middle of the proximal margin. — In f. **ozeta** Plötz there is besides a longish, white submedian spot on the forewing. Brazil, Venezuela. *ozota.*

165. Genus: **Vettius** G. & S.

Antennae remarkably long, club with a long reverted apex. Middle tibiae spined. The ♂ exhibits a triangular scent-spot in the angle of the rise of the lower median vein, and a longitudinal stripe below it.

V. phyllus Cr. (189 b). Above blackish-brown with a longish, white hyaline spot at the lower cell-end and a large, obliquely quadrangular spot below it; behind it and below in front of it there is one smaller spot each, the latter being lustrous silvery, before it grey hairing. Two very small subapical spots, and on the hindwing a hyaline median band composed of 3 oblong wedge-shaped spots: inner-marginal fold in the middle white-haired. Beneath the apex of the forewing is lighter, the hindwing greyish-black, with darker veins, in the costal-marginal half yellow with a brownish-black longitudinal stripe in it. Panama to Brazil. *phyllus.*

V. laurea Hew. (189 b) is very closely allied to the preceding and above scarcely separable, the band of the hindwing at most being broader on an average. Beneath it also resembles *phyllus* very much. The hindwing is of a purer yellow in the larger costal half with a black spot at the costal margin near the apex and two broad, brown longitudinal bands; the lower one borders downwards on the yellow colour, towards the proximal margin on the grey anal colour; base of costal margin and the extreme proximal margin are brownish-red. Guiana, Brazil (Rio de Janeiro), Trinidad. *laurea.*

V. maeon Mab. Above black with two small, white postdiscal spots and a yellowish diffuse spot below the lower cell-end; the spot above it is larger; fringes brown. Hindwing black with an oval-triangular white discal spot being proximally defined in a blurred manner and separated from the inner-marginal fold by a similar spot which, however, extends farther downwards. Forewing beneath black with a white apical spot bordered by red towards the costal margin. Hindwing yellowish-white, at the base shaded with a ferruginous brown, with a blackish spot at the end of the proximal margin and a similar one behind the cell. Expanse of wings: 30 mm. Panama (Chiriqui). *maeon.*

V. elvira Plötz (189 b). Blackish-brown, towards the base and on the body somewhat greyer with a double white cellular spot and 3 postdiscal ones. Beneath reddish violettish-brown, beside the spots on the forewing above with an oblique, yellow subapical band. Hindwing yellowish-grey between the thickly red-brown veins; a broad, yolk-coloured stripe extends through the cell to the distal margin. South America, exact habitat not stated. *elvira.*

V. lafresnayi Latr. (189 c). Above brown with a white-hyaline cellular spot and pendent below it a large, quadrangular spot, above it 2 more small, postdiscal and 3 subapical ones. Hindwing with a white *lafresnayi.*

discal band and an inner-marginal fold haired bluish-white. Hindwing beneath white with a chestnut-brown costal margin, a broadly brownish distal margin and some minute spots in the discal area. Panama to Brazil.

peninsularis. **V. peninsularis** Plötz (189 c) is above similar, but it has no cellular spot and the hindwing is not spotted. Beneath the hindwing is white with a large, blackish-brown triangular spot in the cell and a brown distal margin being broadest opposite the cell and growing very narrow at the anal angle. From Pará.

triangularis. **V. triangularis** Hbn. (= *pica* H.-Schüff.) (189 c) is above similar, but it has a broad, white discal band of the hindwing reaching the proximal margin. Hindwing beneath white, at the costal margin broadly black with a small triangular spot below the cell and a broad blackish-brown margin. The white disc is hued yellowish towards the margin. Brazil.

monacha. **V. monacha** Plötz (189 c) has above rather small white spots; the band of the hindwing is also shortened and does not reach the proximal margin. The under surface is lighter, browner, the white area of the hindwing very extensive and bluish-grey, in some places strewn with brownish. Costal margin red-brown like the broad distal margin except the apex; the small triangular spot is minute. From Pará.

hypargus. **V. hypargus** Mab. is a small, black species with 3 white, subapical hyaline dots and 5 spots in a bent row behind and below the cell-end, but there is no spot between the lower radial veins; in the middle of the proximal margin there is a white-dusted spot and another one in the cell-end. The hindwing exhibits in the middle a large, white triangular spot, behind the lower cell-angle a whitish longitudinal patch. Forewing beneath red-brown, spotted as above. Hindwing in the proximal half yellowish-white, in it with the white spot of the upper surface; the marginal area is red-brown. Expanse of wings: 27 mm. Manaos.

marpesia. **V. marpesia** Hew. (189 d) is a larger, very much white-spotted species with a brown body and brown bases of the wings. Beneath the hindwing is light violet, with brown veins and a white spot before the middle of the distal margin and two blackish spots at the anal angle and above it at the distal margin. The costal margin of the forewing is white, the fringes of the hindwings are also white towards the anal angle. Amazon District.

periphas. **V. periphas** Mab. is above black, the base of the forewing strewn with yellow; the forewing exhibits 3 apical hyaline dots, 2 small ones in the cell and 3 somewhat larger postdiscal ones. The margin of the hindwing is yellowish with a narrow, oval, white longitudinal spot; fringes of hindwing white as far as the lower radial. Beneath the forewing is blackish with a large, yellow, black-veined apical spot. Hindwing at the proximal margin light yellow, in the costal-marginal part yellowish-green, in the discal area brownish. Expanse of wings: 36 mm. Amazon (Massaury).

166. Genus: **Coeliades** Hbn.

Antennae long, with a slender club. Forewing long, with a concave distal margin and a basally convex costal margin. Hindwing at the anal angle feebly lobate; body slender with long legs and bare middle tibiae. The ♂ exhibits a tripartite stigma: a short scent-stripe in the middle of the median between the branches, a longer one on the lower median branch, and the longest on the submedian.

dubius. **C. dubius** Cr. (= *virga* Btlr.) (189 d) is above blackish-brown, towards the margin suffused with a leaden or steel-grey lustre, with 2 small postdiscal and subapical spots. Beneath at the apex of the forewing and on the hindwings deep red-brown or cerise, on the hindwing with a narrow yellow transverse band from the apex to the middle of the proximal margin. Surinam.

elenora. **C. elenora** Ehrm. is unknown to me; we place this species having been described as *Pamphila* to this genus, because the description coincides with that of *dubius* with which it may agree; the scent-organ, however, is not mentioned. Described from Venezuela.

fiscella. **C. fiscella** Hew. (= *balteatus* Mab.) (189 e). Blackish-brown with a large, bipartite cellular spot, a trapezoid spot below it, and farther towards the margin with a submedian, longish small spot and 3 subapical ones in a straight line. Hindwing with a brownish-smoked band across the cell-end. Beneath with the same spots, at the costal margin and apex of the forewing and on the hindwing chestnut-red except the proximal margin of the hindwing, with a yellowish transverse band from the apex of the hindwing to the middle of the proximal margin. Nicaragua to the Amazon.

167. Genus: **Dion** G. & S.

Distinguished from the preceding genus by a stronger, stouter body and the scent-stripe extending from the base of the upper median vein obliquely and somewhat bent to the middle of the submedian.

gemmatus. **D. gemmatus** Btlr. (189 e). Above blackish-brown with a grey stigma. Beneath the forewing is lighter at the apex with darker veins; the hindwings are blacker, in the anal two thirds chestnut-brown, with black veins, in the disc with a black spot with 3 or 4 light-blue eye-dots in it. The ♀ is in the apical half of the forewing above pale reddish-brown with dark brown veins, the apex itself is dark. Costa Rica, Panama.

D. rubrinota *Drc.* (189 f). Above blackish-brown, between the veins lighter. Beneath greyish-brown, *rubrinota*, on the forewing with a yellowish, black-veined postdiscal area. Hindwing greyish-brown, with black veins and internerval streaks with a brick-red costal margin and inner-marginal stripe and a brick-red longitudinal diffuse patch along the lower margin of the cell. Eyes red. The ♀ is also above postdiscally lighter yellowish-white. Peru, Bolivia. — In Colombian specimens: f. *acraea* *Plötz* (189 e) there is only the red stripe below the *acraea*, cell, those at the costal and proximal margins being absent.

D. pruinosa *Plötz* (189 e). Above monotonously blackish-brown with a grey stigma. Beneath the *pruinosa*, forewing, towards the apex at the distal margin, is dusted with violettish-bluish like the whole hindwing except the costal part; some small, postdiscal, brownish diffuse spots. Brazil (Chapada).

168. Genus: **Flacilla** *G. & S.*

Antennae of two thirds of the length of the costal margin with a slender club and an almost semicircularly bent apex; terminal joint of the palp long and pointed. Forewing long with a concave costal margin. The ♂ exhibits a scent-spot from the base of the median to the rise of the lower branch, a stripe below it and a third longer one on the submedian; the hindwing shows long hair in the anal fold.

F. aecas *Cr.* (189 d) is easily recognizable by the steel-blue, white-veined hindwing beneath with *aecas*, a submarginal row of whitish dots; also the costal margin and apex of the forewing is steel-blue; the proximal margin of the hindwing is broad brownish-grey. Panama to Brazil; Trinidad.

F. coatepeca *Schs.* Head reddish-brown, collar and thorax violettish-brown. Wings dark brown, *coatepeca*, forewing with a small, white-hyaline longitudinal spot in the cell, a large spot below it, 2 smaller ones farther distally and 2 subapical, small, quadrangular spots. Beneath dark brownish-red, on the forewing the cell and proximal margin blackish, with the spots as above. Hindwing with a blackish-brown inner-marginal part. Expanse of wings: 42 mm. Mexico (Coatepec).

F. ergola *Schs.* Above brown, the basal third of the costal margin of the forewing as well as the anterior *ergola*, body more red-brown; a large spot between the median veins, and a smaller one above it and farther distally are yellowish-hyaline. Beneath the forewing is black, the costal margin, apex and distal margin are red-brown. Hindwing reddish-brown, at the costal margin darker, with a broad, dark postdiscal shade and a light violet cell. Expanse of wings: 37 mm. Novo Friburgo.

169. Genus: **Cymaenes** *Scddr.*

Antennae long and slender; terminal joint of the palp long and erect. Body slender, middle tibiae bare, in the ♂ a scent-organ.

C. malitiosa *H.-Schäff.* (= *lycaenoides* *Plötz*) (189 e) is above of a plain blackish-brown, beneath *malitiosa*, lighter, the forewing at the costal margin and apex watered red-brown like the whole hindwing which exhibits a broad, irregular dark transverse band being interrupted in the middle and broadest at the costal margin. Mexico to Costa Rica and Cuba and Trinidad. Very closely allied to *silius* (189 f) from which, however, it is easily separated by the hindwing beneath.

C. lutulenta *H.-Schäff.* (189 e) is above like the preceding. Beneath lighter, the hindwing whitish *lutulenta*, and watered with brownish-red, at the costal margin broadly red-brown, in the middle of the lower margin interrupted by a light streak of the ground-colour. Panama to Colombia and Venezuela.

C. silius *Latr.* (*antistia* *Plötz*) (189 f). Blackish-brown with a reddish-yellow oblique band from the *silius*, proximal margin before the base to the apex of the forewing, where it ends narrowed. Costal margin strewn with ochreous. Beneath the costal margin is broader reddish-yellow, otherwise the same; the hindwing is dark ochreous-yellow, strewn with blackish-brown. Mexico to Brazil. Allied to *lunata*, but the reddish-yellow band is narrower, the hindwing beneath lighter.

C. lunata *Plötz* (= *berus* *Mab.*, *insidiosa* *Mab.*) (189 f) is very similar, but the reddish-yellow is much *lunata*, more extensive than in *silius*, so that only a cellular longitudinal stripe and the dentate margin remain dark. Beneath red-brown, towards the proximal margin light ochreous or grey. Hindwing ferruginous-brown, in the disc and at the distal margin dusted with lilac-grey. The species is very variable; specimens from Costa Rica are on the forewing beneath analwards ochreous-yellow, on the hindwing beneath with a more or less distinct, narrow, dark band proceeding from the costal margin near the apex. Costa Rica to Brazil. — f. *silene* *Plötz* is above darker, the reddish-yellow reduced and more red-brown, beneath also darker, on the forewing without the submedian lighter part.

C. syraces *G. & S.* (189 f). Forewing above reddish-yellow with a large, triangular basal spot and *syraces*, quadrangular subapical spot of a blackish-brown colour and a broad, similarly coloured margin. Hindwing below the broad black costal margin in the disc strewn with ferruginous yellow. Beneath the forewing is the same, the hindwing grey or ochreous-yellow, strewn darker, with a dark brown triangular costal-marginal spot and a smaller one below the cell-end; distal margin broadly darkened. Mexico to Guatemala.

C. pericles *Mschlr.* (189 g) is above similar, but more extensively yellowish-brown, especially on the *pericles*, hindwing. Beneath quite different, the hindwing being monotonously yellowish-brown with a narrow black marginal line. Forewing coloured and marked as above. Colombia, Venezuela, Trinidad.

nux. **C. nux** Schs. Above dark brown, with 3 small, white, postdiscal hyaline spots in an oblique row and a very small subapical dot; fringes of hindwing white. Beneath the forewing is blackish-brown, at the apex lighter, in the middle of the distal margin shaded darker; the lowest spot is larger than above and not transparent. Hindwing whitish, streaked brown, costal margin brown with a large, dark spot below the cell-end, traversed by the light median veins. Expanse of wings: 35 mm. Novo Friburgo.

lucia. **C. lucia** Capr. (189 g). Dark brown with a curved postmedian band of lighter spots and lighter speckled fringes. Beneath in the apical part of the forewing and on the hindwing reddish-grey, watered with dark brown, with broad, brownish-grey or violettish-grey demi-bands proceeding from the darkened anal part and taperingly not reaching to the costal margin. Brazil.

dubitans. **C. dubitans** Schs. Above dark brown with a feeble light brown oblique shade behind the cell. Beneath olive-brown, the proximal margin of the forewing greyish-brown; hindwing in the middle of the distal margin tinted violet, at the costal margin darker with a dark oblique shade from the apex to behind the cell. Expanse of wings: 29 mm. Novo Friburgo.

intermedia. **C. intermedia** Schs. (189 g). Dark brown with a light olive-brown diffuse patch from the middle of the proximal margin to the lower cell-end; hindwing haired olive. Beneath the forewing is dark brown, the proximal margin not lighter. Hindwing dark olive-grey, densely striated brown, at the costal margin darker, with a dark shade from the cell-end to the apex. Expanse of wings: 28 mm. Brazil (Tijuca), also found in Mexico.

occulta. **C. occulta** Schs. Above dark brown, beneath duller, dusted with reddish, on the forewing the inner-marginal part lighter brown. The hindwing exhibits a dark oblique shade from the lower median vein to the apex, the proximal margin is lighter brown. Expanse of wings: 29 mm. Rio de Janeiro.

170. Genus: **Mnaseas** G. & S.

Antennae shorter than half the costal margin; terminal joint of the palp long and slender. The ♂ exhibits a narrow, interrupted scent-scale stripe from the base of the lower median vein obliquely to the first third of the submedian. Only 1 species:

bicolor. **M. bicolor** Mab. (= bias Plötz) (189 g). Above lustrous blackish-brown with a stigma of the same colour. Beneath lighter, the forewing at the costal margin and apex, and the hindwing is ferruginous brown; the fringes are dirty ochreous-yellow. It greatly resembles *Mastor anubis* (187 g) and is separable by the narrow, oblique stigma and the longer, slender terminal joint of the palp. Mexico to Colombia.

171. Genus: **Methionopsis** G. & S.

Antennae long with a long club; terminal joint of the palp long, erect. Stigma bipartite: one part rests on the middle of the median, the other side of the angle on the lower median vein. In *typhon* the lower side of the angle is absent.

ina. **M. ina** Plötz (= modestus G. & S., philemon Btlr.) (189 g). Above blackish-brown with a similarly coloured stigma. The forewing exhibits some postcellular ochreous-yellow scales. Beneath the same, at the proximal margin of the forewing somewhat lighter. Mexico to Brazil.

typhon. **M. typhon** G. & S. is above the same. Beneath tinted somewhat purple; on the whole smaller, the stigma less developed. Guatemala.

caerulans. **M. caerulans** Mab. is somewhat smaller than *ina*, above blackish-brown. Beneath black, in the disc of the forewing there are 2 small grey dots, the hindwing shows 4 or 5 dots at the distal margin; the costal and distal margin of the forewing as well as the disc of the hindwing show a bright blue reflection. From Pará.

172. Genus: **Eutocus** G. & S.

Antennae and palpi as in the preceding genus. Cell of forewing three fifths of the length of the costal margin; the middle radial at its rise very much bent and nearing the lower radial; body slender. Middle tibiae without spines. The ♂ exhibits a sagittiform scent-scale stripe in the angle between the median and its lower branch.

phthia. **E. phthia** G. & S. (189 g) is blackish-brown, stigma of the same colour; the forewing exhibits some small, ochreous-yellow postcellular scales. Beneath the same, at the proximal margin lighter, at the costal margin and apex, and on the hindwing scantily strewn with ochreous. Smaller than *M. ina* which it very closely resembles, only separable by the stigma and veins. Mexico to Guiana.

volasus. **E. volasus** G. & S. is very closely allied to the preceding, beneath more reddish, only very diffusely strewn with ochreous. The stigma is less distinct. Panama.

173. Genus: **Eprius** G. & S.

Antennae and palpi as in the preceding; on the forewing the middle radial vein is less far depressed. The ♂ stigma consists of 2 longitudinal stripes, one of which is situate on the median between its branches, while the other extends proximally to it as far as the rise of the lower branch; the hindwing shows very long hair at the proximal margin of the abdominal fold.

E. valeda G. & S. (189 g). Blackish-brown with a similarly coloured stigma. Beneath scantily strewn *valada*, with yellow; base of antennal club beneath ochreous-yellow. Mexico to Panama, Trinidad.

174. Genus: **Mnasicles** G. & S.

Distinguished from the preceding genus by the ♂ stigma extending from the rise of the lower median vein obliquely to the middle of the submedian, being broad, though indistinct and interrupted.

M. geta G. & S. (189 g) is blackish-brown with a similarly coloured *stigma*. Beneath scarcely lighter, *geta*. The forewing at the proximal and distal margins and the hindwing in the basal half and at the distal margin scantily strewn with lilac grey. Base of antennal club beneath ochreous-yellow. Mexico to Costa Rica.

M. hicetaon G. & S. resembles *geta* above. Beneath lighter, the forewing in the middle darker, at *hicetaon*. the costal margin and apex as well as the whole hindwing scantily strewn with ochreous-yellow. Mexico.

M. rivera Plötz (189 h) is twice as large as *geta*, above almost black, beneath more variegated, at *rivera*. the distal margin of the forewing in the upper half tinted yellowish-grey with a subapical, light costal-marginal spot and an inner-angular spot. Hindwing with a yellowish-grey apical band and a lighter grey distal margin and proximal margin. From Rio de Janeiro.

175. Genus: **Callimormus** Scddr.

Separated by the ♂ scent-organ being composed of 2 stripes, one of which in some species is acute-angular with differently long sides on the middle segment of the median, the other being below the submedian. Terminal joint of the palp long, slender and pointed and almost vertically erect.

C. juvenus Scddr. (189 h) is above dark brown, behind the stigma with 2 or 3 small, indistinct ochreous *juvenus*. spots. Beneath with lighter yellow veins, a darker marginal band and basal part, so that a postdiscal band of light yellowish spots is prominent. Mexico to Brazil.

C. polita Plötz (189 h) is above similar, but especially on the hindwing with broad ochreous-yellow *polita*. fringes. Beneath the hindwing is much darker, olive-blackish, with yellow veins and a double postdiscal row of yellow dots. Patria unknown.

C. filata Poey (= *radiola* Mab.) (189 h) differs from *polita* by its larger size, darker ground-colour *filata*. and just as dark fringes. Beneath the same, at the apex of the forewing, and on the hindwing with yellowish veins. Panama to Colombia, Venezuela, Guiana, Brazil, in Cuba and Trinidad. Distinguished from *Parphorus storax* (188 a) by a longer terminal joint of the palp and a different stigma, being larger than the likewise very similar *gracilis* with distinct yellow veins.

C. vetula Mab. (= *interpunctata* Plötz) (189 h) is above purer black, with a slight steel reflection *vetula* and darker veins, beneath as *polita* from which it differs by entirely dark fringes. Brazil (Bahia, Pará).

C. fabulinus Plötz (189 h) is allied to the preceding, larger, more slender, above browner with *fabulinus*. traces of small, lighter, postdiscal, subapical and cellular spots. Beneath somewhat darker than *vetula*, otherwise the same. Surinam.

C. gracilis Fldr. (= *alsimo* Plötz) (189 k) is above darker than *juvenus*, beneath without light *gracilis*. discal spots; forewing above at the costal margin, between the median veins and at the cell-end scantily strewn with yellow. Beneath the apex of the forewing, and the hindwing with light ochreous-yellow veins. Mexico to Colombia and Venezuela.

C. corades Fldr. (= *decrepida* H.-Schäff., *tenera* Plötz) (189 k) has above mostly more distinct ochreous- *corades*. yellow cellular, postdiscal and subapical spots than the other species; but they may also be fainter or almost absent. Beneath the hindwing is yellowish or more lilac-grey with a postdiscal row of dots and a darker marginal band. Mexico to Brazil and in Trinidad.

C. diaeses Schs. Above dark brown with lighter fringes and on the forewing some small ochreous- *diaeses*. yellow postdiscal scales. Beneath brown, dusted with violet, apex of forewing and distal margin with yellow veins, hindwing with yellow veins and a discal streak and a postdiscal row of minute whitish spots. Expanse of wings: 19 mm. South Eastern Brazil.

- elides.* **C. elides** Weeks. Above dark brown, on the forewing with 2 white subapical dots; postdiscally below the cell 2 small white spots. Beneath lighter, hindwing more ferruginous-brown, basally still lighter, at the costal margin with a diffuse spot of the ground-colour; a short, lighter, postdiscal band. Expanse of wings: 1 inch. Venezuela (Suapure).
- verames.* **C. verames** Schs. is a somewhat larger species. Above dark brown with lighter fringes; on the forewing the costal margin shows olive-greenish scales, and similar scales are situate postdiscally in the shape of small indistinct spots. Beneath the forewing is brown, at the proximal margin lighter with a yellow marginal line; subcostal veins as far as the middle radial yellow, a longitudinal streak in the cell and the median veins at the distal margin being yellow, too. Hindwing violet, with bright yellow veins; inner-marginal part dusted with yellow; an antimarginal row of yellow spots. Expanse of wings: 22 mm. Peru.

176. Genus: **Mnestheus** G. & S.

Chiefly distinguished from *Callimormus* by a different scent-organ consisting of 2 short longitudinal stripes, one of which is situate in the angle of the rise of the lower median vein, the other being right below it.

- ittona.* **M. ittona** Btlr. (189 k). Above blackish-brown with a similarly coloured stigma. The forewing shows 3 white postcellular spots in an oblique line. Beneath the same, the lowest spot extinct. The proximal margin of the hindwing and a broad band from the proximal margin to the middle of the distal margin are silvery or yellowish-silvery, both flowing broadly together at the costal margin. In southern specimens the hindwing is more red-brown instead of blackish-brown. Panama to Bolivia.
- cometho.* **M. cometho** G. & S. (189 k) is above blackish-brown, the spots arranged as in the preceding, but ochreous with another small, subapical one; disc of hindwing reddish-yellow. Beneath lighter, the veins of the costal margin, apex and distal margin being ochreous-yellow as well as those on the hindwing, between them there are small, whitish postdiscal spots. By its larger size and the ochreous-yellow spots it differs from *ludens*; larger than *virginius*, with much more distinct spots on both wings beneath. Mexico.
- ludens.* **M. ludens** Mab. Above like *cometho* (189 k), but the spots whitish-hyaline. Beneath without the white internerval spots; the yellow veins on the hindwing beneath are interrupted at the cell-end. Panama to Venezuela.
- virginius.* **M. virginius** Mschlr. (189 k) resembles *cometho* above, but it is smaller; beneath blackish-brown with yellow veins except the inner-marginal half of the forewing, the spots of the forewing above being also beneath faintly visible, especially below the subapical ones two being removed far towards the margin. Surinam.
- petrovna.* **M. petrovna** Schs. looks above like *cometho* (189 k), the spots of a purer yellow and diaphanous except the lowest above the submedian, which is triangular and not transparent; in the cell there is also a spot; hindwing in the disc dusted yellowish with small postdiscal yellow spots. Beneath the forewing is dark brown, spotted as above with yellow veins at the distal margin and apex and subcostally; hindwing violet, with brownish-yellow veins and an undulate yellow postdiscal line; inner-marginal part brown bordered with yellow. Expanse of wings: 26 mm. Petropolis.

177. Genus: **Epinosis** Schs.

♂ with hairy, erect palpi. Antennae more than half as long as the costal margin, towards the bent and pointed end thickened. Wings broad; on the forewing the lower median vein rises from the middle of the cell, the upper one close before the angle; transverse vein oblique, below the middle it dispatches the lower radial; below the median between the branches with a narrow scent-stripe. Only 1 species.

- parvipuncta.* **E. parvipuncta** Plötz (= *angularis* Mschlr.) (186 d) is above blackish-brown with a slight greenish reflection on the thorax and bases of the wings, on the forewing with one minute postdiscal and subapical dot each; fringes somewhat lighter, more yellowish. Beneath the same, scarcely lighter, only the submedian area of the forewing is brownish-grey and the distal margin of the hindwing is a little lighter brown. Fringes with a yellowish tint. Costa Rica to Guiana.

178. Genus: **Artines** G. & S.

Antennae and palpi long, as in the preceding genera. The ♂ stigma is sagittiform and situate in the angle of the rise of the lower median branch and the median; hindwing at the anterior edge of the abdominal fold with long hair. In *atizies* the stigma is absent.

- atizies.* **A. atizies** G. & S. (190 a). Blackish-brown, on the forewing with 2 small whitish spots below and behind the cell in an oblique line and 2 small subapical ones. Beneath lighter, at the apex of the forewing and on the hindwing dusted with lilac; spots on the forewing as above, analwards whitish with a subapical, narrow, blackish-brown band which is crossed by light veins. Hindwing with large, black dots encircled by ochreous-yellow, and 5 blue-pupilled spots. Panama, Venezuela, Guiana, Brazil and Trinidad.

A. aepitus *Hbn.* (190 a). Above black with 2 small postdiscal and 1 minute subapical white spot. *aepitus*. Beneath the forewing at the apex and the hindwing are violettish-grey, in the disc lighter, more bluish-white, with a thick black spot at the cell-end and behind it a curved band of faintly ochreous-yellowish spots, on both sides bordered with black. Brazil.

A. aquilina *Plötz* (= *tertius Strd.*) (190 a) is similar, somewhat smaller, above not different. Beneath *aquilina*. the apex of the forewing is lilac with a row of black dots; the hindwing is lilac-grey with a postmedian dentate band of bluish-violet, on both sides bordered with black; between it and the margin there is another black dentate line; the space between both and behind the cell contains dispersed ochreous-yellow scales. Brazil (Santos, Minas Geraes).

A. anna *Mab.* is questionable as to its position. Blackish-brown, forewing with 3 small subapical *anna*. dots, below them 4 small yellowish clouds. Hindwing with a yellowish discal reflection, fringes yellowish-brown. Forewing beneath light greyish-red, at the apex and costal margin blackish; spots more distinct than above, in the submedian area 2 white diffuse patches. Hindwing light reddish-grey, in the cell with a roundish, lilac brightening and a brown streak in it, and in a semicircle behind it 5 lilac spots on both sides bordered with black. Bolivia.

A. ursula *sp. nov.* (190 a) somewhat resembles *anna*. Above plainly blackish-brown with traces *ursula*. of lighter postdiscal and subapical diffuse spots. Beneath dull blackish-brown, apex of forewing and proximal angle lighter grey, the former with a roundish spot of the ground-colour in it, the 2 postmedian spots more distinct than above. Hindwing in the disc with large black spots, only separated by the light veins and the transverse vein; behind these spots, parallel to the distal margin, 5 oblong, bluish-violet spots, also distally bordered with black. From the Upper Madre de Dios (South Peru) from the Coll. FASSL.

A. acroleuca *Plötz* (189 k) is above black with a whitish apex of the forewing before the black fringes. *acroleuca*. Beneath lighter brown with whitish postdiscal and subapical macular bands; that on the hindwing is distally pupilled with black; both wings exhibit fine black undulate lines before the distal margin; the hindwing besides a small white, black-pupilled cellular dot. Brazil.

A. farinosa *sp. nov.* (190 a) is larger, above with a minute subapical dot, 2 white postdiscal spots *farinosa*. and a yellowish submedian patch. Beneath similar as *aepitus*, hindwing densely strewn with white, with a very large, jet-black cellular spot surrounded by bluish-white; behind the cell there are oblong bluish-white wedge-shaped spots, parted by the brownish veins and proximally and distally narrowly bordered by brown, distally touching the broad dark brown distal margin. According to several specimens from Colombia (Rio Aguaca and Rio Negro), taken by FASSL.

A. melitaea *sp. nov.* (190 a) is above uni-coloured brown, ends of fringes somewhat more whitish, *melitaea*. on the forewing with 3 small, lighter, subapical diffuse spots which may also be absent. On the but slightly duller under surface they are distinctly prominent as 3 to 5 small, oblong, whitish spots, behind them close before the apex a small white spot. Hindwing in the disc white, basally somewhat, towards the margin more broadly and intensely smoked brownish, with 3 or 4 dark brown, somewhat dentate lines marked like *Melitaea*, partly their interspace is strewn with brownish; before the margin parallel to it some more, small, whitish, diffuse spots. Fringes on the veins somewhat speckled. Rio Aguaca Valley (Colombia); FASSL.

A. pavo *sp. nov.* (190 a). Above blackish-brown, forewing with 2 white postdiscal spots, an indis- *pavo*. tinctly lighter submedian diffuse spot and 2 minute, scarcely visible subapical dots. Beneath somewhat duller brown; on the forewing marked the same, before the distal margin a somewhat curved, rather indistinct band of darker nebulous spots. Hindwing in the disc white, towards the proximal margin bluish, at the base inclusive of the costal margin and at the distal margin brownish, the median and radial veins behind the cell ferruginous, between them are 3 long, jet-black, wedge-shaped spots exhibiting round, bluish-white pupils near the distal end. In the ♀ these spots are confined to 2 small, roundish, black, not pupilled spots, the discal area is more yellowish. A couple taken by FASSL on the Songo (Bolivia).

179. Genus: **Falga** *Mab.*

Antennae and palpi as in the preceding. Wings particularly long and narrow, costal margin of forewing at the base convex, hindwing at the anal angle somewhat lobate. Body long and slender. The ♂ shows a tripartite scent-organ: a stripe in the middle of the median, another one below the lower median branch, and a third before the middle of the submedian.

F. jeconia *Btlr.* (190 a) is above blackish-brown with a yellow longitudinal stripe below the cell *jeconia*. of the forewing and a yellow spot almost covering the whole hindwing. Beneath the apex of the forewing and the whole hindwing are uni-coloured yellow. Venezuela. — f. **abalus** *Mab.* (190 b) has almost entirely black *abalus*. forewings, the hindwing beneath towards the proximal margin strewn with brown; found in Colombia.

F. sciras *G. & S.* (190 b) is above almost quite reddish-yellow, only at the apex and distal margin *sciras*. of the forewing broadly blackish-brown, like the basal and costal veins; hindwing broadly bordered with blackish-

brown, the broadest at the anal angle. Beneath blackish-brown with a large, oval, ochreous-yellow discal spot of the forewing the apex of which is reddish-yellow; hindwing light yellow with 2 small blackish-brown discal spots and an indistinct macular band parallel to the distal margin. Honduras.

hermione.

F. hermione *Schs.* It is questionable to which genus it belongs. Above black with an orange subcostal vein and a broad, orange-brown postmedian shade united with a similar stripe-spot below the cell. Hindwing orange-brown, bordered with black. Fringes orange, on the forewing spotted black. In the ♀ the orange colour is not so extensive on the forewing. Costa Rica.

180. Genus: **Enosis** *Mab.*

Antennae $\frac{2}{3}$ of the length of the costal margin; palpi ascending with a short, conical terminal joint. Forewing broad, at the base convex. Body slender, with very long legs. ♂ with a tripartite scent-scale spot: a triangular spot in the angle where the lower median vein rises, a short longitudinal stripe below it and a similar one before the middle of the submedian.

quadrinotata.

E. quadrinotata *Mab.* (190 b). Above blackish-brown with a similarly coloured stigma. Beneath lighter, with a broad, grey proximal margin of the forewing; in the disc 2 small light dots. Hindwing with 4 yellowish discal dots, the apex of the forewing, costal margin and the hindwing scantily strewn with yellow. Panama.

simplex.

E. simplex *Mab.* is above and beneath jet-black, on the forewing with 2 small white hyaline dots before the apex and a third farther below. The under surface exhibits the same dots and besides on the hindwing a grey postcellular dot. Fringes white, towards the tips somewhat smoky. Expanse of wings: 42 mm. Venezuela.

atrata.

E. atrata *Mab.* is as large as *simplex* and on both surfaces quite uni-coloured black without any spots. Fringes purely white. Discernible from the very similar *immaculata* (190 b) by the forewing being at the apex somewhat longer, more pointed and by the entirely white fringes. Colombia.

dognini.

E. dognini *Mab.* Blackish-brown, in the disc of both wings somewhat lighter reddish. The forewing exhibits 3 small, white, subapical hyaline dots and a quadrangular, similar spot behind the lower cell-angle. Beneath the forewing shows a broad whitish band from the apical dots to the proximal margin, the hindwing a postdiscal band of 6 oblong-quadrangular silvery spots, the uppermost of which is only half as large as the others, owing to an ochreous-yellow spot in front of it. Expanse of wings: 42 mm. Ecuador (Loja).

immaculata.

E. immaculata *Hew.* (190 b) is above uni-coloured blackish-brown, with fringes of an ochreous-yellowish reflection, and a very slight bronze-green reflection on the body and wings. Beneath the same, of a scarcely duller colour. Venezuela.

inframaculata.

E. inframaculata *Strand.* We cannot tell to what extent this species may be identical with *quadrinotata*. Above blackish-brown with single yellow hair-scales in the costal half of the forewing. Beneath the forewing shows 2 roundish, yellow, small spots, the hindwing a postdiscal transverse row of small yellow spots. Costa Rica.

181. Genus: **Carystoides** *G. & S.*

Antennae $\frac{2}{3}$ of the length of the costal margin; palpi ascending, last joint hidden. Body robust. Middle tibiae without spines. ♂ without a stigma.

basochesii.

C. basochesii *Latr.* (= *argyrocoryne* *Mab.*) (190 b). Above blackish-brown with light brownish-grey fringes, a more or less broad, white apex of the forewing before them, and 3 hyaline discal spots, the hindwing with a tripartite discal spot. Beneath the apex of the forewing is grey with 3 dark dots in it. Hindwing particularly at the base densely strewn with yellowish-grey. Honduras, Panama, Colombia, Brazil and Trinidad. — f. **replana** *Plötz* (190 b) has the spot of the hindwing reduced to 2 minute spots, — and f. **valentina** *Plötz* (190 c) has on the forewing much smaller discal spots, and on the hindwing the discal spots as 3 separate small spots. The latter form originates from Surinam. — f. **benchos** *Weeks* from Bolivia resembles *replana*, but it has another, small, subapical spot on the forewing.

replana.

valentina.

benchos.

sicania.

C. sicania *Hew.* is above red-brown, with a white apex of the forewing, a tripartite hyaline discal spot and a small subapical dot; also the hindwing exhibits a hyaline spot in the middle. Beneath as above, but the costal margin and apex of the forewing, as well as the hindwing are red, the latter towards the base somewhat lighter. Expanse of wings: $1\frac{3}{4}$ inch. From Brazil.

cathaea.

C. cathaea *Hew.* (190 d) differs above from the preceding by the absence of a spot on the hindwing, being otherwise very similar. Beneath quite different, the apex of the forewing, and the hindwing greyish-brown, tinted violet, with whitish, dark-edged veins and blackish longitudinal patches on the hindwing, 2 in the costal half and a broader one along the inner-marginal fold. From Pará. — f. **boliviana** *form. nov.* (190 b) from the Songo has a somewhat smaller cellular spot and the apex of the forewing is not white.

boliviana.

182. Genus: **Lychnuchoides** *G. & S.*

Antennae half as long as the costal margin. Cell of forewing very long and broad, $\frac{2}{3}$ of the length of the costal margin; hindwing at the anal angle lobate. Body stout, densely haired. The ♂ has an angular stigma, the upper part of which borders on the middle of the median, the lower on the lower median branch. MABILLE places here also *hiarbas* Cr. (= *ozias* Hew.) having been dealt with by us as *Ancistrocampta* on p. 879; (190 c).

L. saptine *G. & S.* (190 c) is a large, blackish-brown species with a darker stigma, a broad, ochreous-yellow, centrally hyaline transverse band; apex of hindwing yellow. Beneath the same, at the apex of the forewing lilac-grey; hindwing red-brown clouded with grey. Larger than the very similar *Ancistrocampta celsus* (171 a), the yellow band more irregular and the under surface different. Costa Rica, Panama.

183. Genus: **Nyctus** *Mab.*

Distinguished from *Carystus* by the long, horizontally porrect palpi; hindwing extended into a broad, obtuse lobe; at the base of the inner-marginal fold there is a very long hair-tuft; and on the median veins are also long, bent hairs partly extending beyond the margin of the wing and touching the abdomen.

N. crinitus *Mab.* is a magnificent, velvety black species with a very broad orange oblique band exhibiting proximally 3 angular projections (subcostally, on the lower median vein and on the inner-marginal vein), and being distally gnawed out at the lower cell-angle. Hindwing at the costal angle with an orange marginal line and fringes; the hair-pencil with a green reflection. Beneath the forewing is red-brown, the hindwing black with brilliant green veins. Expanse of wings: 52 mm. Brazil (Pebas).

N. triangularis *Kaye.* Above dark brown, costal margin and the larger inner-marginal half lighter. A cellular spot and 4 postdiscal spots yellowish hyaline as well as 2 subapical dots. Hindwing with 3 small spots in one line behind and below the cell. Collar golden yellow. Beneath very much lighter, especially the base of the hindwing. Expanse of wings: 42 mm. Trinidad.

184. Genus: **Lychnuchus** *Hbn.*

Antennae long, the long club exhibits a slender, long apex. The terminal joint of the ascending palpi is hidden. The anal angle of the hindwing is lobate, above it somewhat concave. The ♂ shows a bipartite stigma: a stripe on the central part of the median between the branches, another one on the lower median vein. We enumerate here only two species, the third: *celsus* F. (= *clarchus* Plötz) (171 a) which is inserted here by MABILLE, we have already dealt with in *Ancistrocampta* on p. 879. As to the synonymy of the species and genera there is still much uncertainty prevailing. Comp. also the genus *Lychnuchoides* (t. 190 c).

L. olenus *Hbn.* (190 c) is of a plain blackish-brown with a very broad orange discal band which is semi-diaphanous in its central part. Beneath the same, but the brown is slightly duller and more reddish. Widely distributed in South America: Brazil, Colombia, Bolivia.

L. pertica *Plötz* (190 c) resembles *Ancistrocampta celsus* (171 a), but the narrow discal band is white, only at the costal margin somewhat yellowish, and there are 3 white subapical punctiform spots. Beneath somewhat duller brown, otherwise the same. Palpi beneath ochreous. South America, habitat not exactly stated.

185. Genus: **Tisias** *G. & S.*

Antennae longer than the cell of the forewing. Terminal joint of the palp short. Forewing long with a bent costa; hindwing at the anal angle lobate. Body robust. Middle tibiae with spines. The ♂ has an angular stigma on the middle of the median and the lower median branch, a longitudinal stripe below it, and a₁' still longer one on the submedian.

T. myna *Mab.* (190 e). Blackish-brown, with a similarly coloured stigma, and 4 large hyaline white spots, 3 postdiscal ones and 1 cellular spot. Hindwing with a small cellular spot and 2 near the distal margin. Beneath lighter, the costal-marginal area behind the cell grey; the submedian spot is larger than above. Panama.

T. quadratus *H.-Schöff.* (190 d) has a double cellular spot, and only 2 postdiscal ones; on the hindwing there are 4 postdiscal spots and the cellular spot is absent. Body and bases of wings with a faint bluish-green reflection. Beneath the apical half of the forewing, and the hindwing are ferruginous-brown, the hindwing the lightest in the apical half, with the spots of the upper surface and a broad white anal angle of the forewing. Brazil.

186. Genus: **Themesion** G. & S.

The long antennal club exhibits a very long, reverted apex; last palpal joint short. Cell of forewing shorter than two thirds of the costal margin; the abdomen projects beyond the hindwing. Body very robust; middle tibiae without spines; posterior tibiae with 2 pair of spurs, the upper being very short.

certima. **Th. certima** Hew. (= *lebbaeus* Hew., *lota* Hew.) (190 e) is above rather similar to *T. myna* (190 e). Blackish-brown with 4 large, hyaline white discal spots and 2 small subapical spots. Hindwing with 1 or 2 small postdiscal dots. The under surface is lighter, in the middle of the forewing darker. The hindwing exhibits a dark dot at the cell-end, and 4 behind it, 2 of which are pupilled white. Panama to Venezuela.

nosedata. **Th. noseda** Hew. (= *brinoides* Mschlr.) (190 e). Above dark brown, towards the base with a slight violettish-brown tint, a white cellular spot and 3 postdiscal ones, the submedian one of which is the smallest. Hindwing with a white spot behind the cell. Fringes ochreous-brownish. Beneath the costal margin and apex of the forewing as well as the whole hindwing are violettish-grey, the disc and inner-marginal part of the forewing black, marked as above. Described from Surinam.

alda. **Th. alda** Plötz (190 d) is above blackish-brown, at the base of the costal margin of the forewing somewhat more reddish with 2 large discal spots, and 1 smaller one each behind and above them. On the hindwing there are towards the apex 1 to 3 small white spots which may also be entirely absent. Beneath the costal margin and apex of the forewing and the whole hindwing are greyish-brown, tinted violet, on the hindwing there are some small black punctiform spots. Brazil.

maroma. **Th. maroma** Mschlr. (190 d, e) is very similar, but the cellular spot is very much strangulated and farther remote from the spot below it, the submedian spot is yellowish, and there are besides 1 to 3 small subapical spots. Beneath darker brown than in *alda*, and mostly yet with a small white cellular spot on the hindwing. Surinam.

moeros. **Th. moeros** Mschlr. (190 f). Here the cellular spot is above divided into 2, and below the subapical spots there are yet 2 small punctiform spots farther towards the margin. Body, base of wings, and hindwings are haired olive-brown. Beneath the costal margin and apex of the forewing as well as the whole hindwing are deep dark green with fine black veins, the hindwing with a black cellular dot and 2 or 3 behind it. Proximal margin of hindwing blackish-grey. Described from Surinam.

orbis. **Th. orbis** G. & S. is smaller than *certima* (190 e), the discal spots ochreous-yellow, with one more submedian spot; the hindwing exhibits 3 postdiscal dots in one row. Beneath lighter, dusted with lilac. The species very much resembles *Carystoides sicania* which, however, is without the yellow submedian streak, the discal spots being also differently placed and only one subapical spot being present. It also greatly resembles *Turesis lucasi* and *theste* (190 f), but the short upper spurs of the posterior tibiae preclude their relationship to the genus *Turesis*. From Nicaragua.

187. Genus: **Turesis** G. & S.

Antennae $\frac{2}{3}$ of the length of the costal margin. Veins as in *Carystus* (p. 979). Body strong, middle tibiae bare, posterior tibiae with double, long spurs.

lucasi. **T. lucasi** F. (= *complanula* H.-Schäff., *yema* Plötz, *hebon* Mab., *silacea* Mschlr.) (190 f). Above like *Th. orbis*, the spots larger, more whitish; hindwing with only one yellowish dot. Beneath lighter, more reddish, the submedian spot of the forewing larger, more yellow. It somewhat resembles *Thr. salius* (191 e, f). Panama to Venezuela, Amazon, Brazil, Antilles.

theste. **T. theste** G. & S. (190 f) is similar, smaller; the 3 discal spots are combined forming an angular spot parted by the veins; a small subapical spot, the submedian spot absent; hindwing without any spots. Beneath lighter, more reddish, on the hindwing with a yellow cellular dot. Costa Rica.

brooksi. **T. brooksii** Weeks may belong hereto. Above dark brown with 3 white subapical dots, a white cellular spot and 2 postdiscal ones. Beneath black, spotted as above, at the costal margin and apex reddish-brown. Hindwing reddish-brown, in the basal and marginal areas darker with 2 white postcellular dots. Expanse of wings: 5 cm. Venezuela (Suapure), taken at the end of July.

188. Genus: **Megaleas** G. & S.

Different from *Turesis* only by the ♂ scent-scale spot: it extends from the rise of the upper median vein obliquely and interrupted somewhat before the middle of the submedian. Antennal club thick and long.

synna. **M. synna** G. & S. (190 e) is a very large species: above blackish-brown with a large, oblong, yellow cellular spot filling up the distal $\frac{3}{4}$ of the cell; behind it and below it a very large tripartite spot, and 3 small subapical spots. Hindwing with a cellular dot and 3 larger dots in the costal-marginal half behind it. Beneath lighter, more reddish. Costa Rica.

189. Genus: **Lycas** G. & S.

The antennae attain the length of the cell of the forewing; the club is long and slender. Cell of forewing of $\frac{2}{3}$ of the length of the wing and pointed at the apex. Body strong, middle tibiae spined. The ♂ has no scent-scales.

L. argenteus Hew. (191 a). Blackish-brown, base of forewing and proximal half of hindwing haired *argenteus*, ochreous-brown; in the disc there are 3 yellow hyaline spots in an oblique row, one of which is submedian; in the cell there is a distally concave spot, subapically 3 dots. On the hindwing the apical half of the costal margin and a submarginal spot are ochreous-yellow. Beneath the same, apex of forewing grey, anal angle spotted whitish. Hindwing silvery with a chestnut-brown band from the middle of the costal margin to the anal angle, being narrower or interrupted at the cell-end; distal margin red-brown. Fringes of hindwing dotted ochreous-brown. Mexico to Brazil.

L. godarti Latr. (= ceraca Hew.) (191 a) is similar, the basal half of the costal margin ferruginous- *godarti*, brown. Beneath in the basal third of the forewing blackish-brown, apex and costal margin more reddish, in the middle of the costal margin there is a yellow spot. Hindwing chestnut-red, at the distal margin lighter with 2 oblique silvery bands. Panama, Guiana, Brazil.

190. Genus: **Orphe** G. & S.

The long antennae reach to the cell-end, club slender; terminal joint of the palp short and hidden. Middle tibiae not spined. The ♂ scent-stripe extends obliquely from the rise of the lower median vein to the inner-marginal vein.

O. gerasa Hew. (= subcordatus Mab., milo Mab.) (191 a). Above black, scent-stripe silvery grey, *gerasa*, fringes brownish; forewing with a cellular spot and 4 postdiscal and 3 subapical small white spots. Beneath duller blackish-brown, at the distal margin and anal angle of the forewing as well as at the margin and in the disc of the hindwing tinted violet; before the margin of the hindwing with a black nebulous band beginning broad at the costal margin and dying away towards the proximal margin. Colombia, Amazon.

O. vatinius G. & S. entirely resembles the preceding except the stigma showing a very distinctly *vatinius*, undulate upper surface, whereas in *gerasa* it is smooth, only at the lower edge with a ridge-like elevation. Guiana, Amazon, Peru.

O. porius Mab. It was impossible to find a description for this name *porius*.

191. Genus: **Damas** G. & S.

Antennae and palpi as in the preceding genera. Hindwing at the anal angle somewhat prolonged and before it slightly concave. Body robust, femora very hairy and middle tibiae spined. The ♂ stigma consists of a triangular part in the angle where the lower median vein rises and a longitudinal stripe below it.

D. clavus Erichs. (= ampyx Mab., corope H.-Schäff., angulis Plötz, cervus Mschlr.) (191 h). Blackish- *clavus*, brown, with a grey stigma, an oblong, yellow-hyaline cellular spot, 3 postdiscal and 3 subapical ones, which may also be absent. Beneath the apical half of the forewing, and the hindwings are tinted violet. Panama to the Amazon.

192. Genus: **Orses** G. & S.

Distinguished by very long antennae of more than $\frac{2}{3}$ the length of the costal margin, with a long, slender club and a long reverted apex. Forewing with a slightly convex costa; in the ♂ the upper median vein rises far before the lower cell-end, in the ♀ close at it, the submedian is in the ♂ somewhat angular. Hindwing analwards prolonged. Middle tibiae without spines; in the ♂ a scent-scale stripe extends obliquely from the rise of the upper median vein to the lower.

O. cynisca Snsn. (= catina Hew., poyas Reak.) (190 f) is a very easily recognizable species. Above *cynisca*, black, in the ♂ with 3 yellow discal spots situate close together, in the ♀ with a white oblique band; fringes and margin of the hindwing apically broad white, in the ♂ more yellowish-white. Beneath the same, but the discal spots are prolonged yellow as far as the costal margin. Distributed from Mexico to Colombia and Brazil.

O. iricolor G. & S. (191 b) is above similar, but on the body and base of the wings haired bluish- *iricolor*, green, particularly on the proximal margin of the hindwing. The under surface is quite different: on the hindwing with 2 oblique, parallel, sulphur-yellow bands from the apex to the distal margin and from the basal third of the costal margin to the anal angle; the hindwing is rather long extended. Venezuela.

O. itea Snsn. (190 f, g) above entirely resembles *cynisca* (190 f), but the very large, in the ♂ yellow, *itea*, in the ♀ white discal spots are of a rounder shape. Beneath very easily recognized by the light grey, black-veined wings, the hindwing showing 2 light yellow bands at the apical distal margin and from the base of the costal margin to the anal angle. Brazil.

193. Genus: **Oenides** Mab.

Antennae long and slender, with a long, pointed club; palpi appressed to the face, ascending, with a short terminal joint. Forewing triangular with a straight distal margin; cell shorter than two thirds of the costal margin. Hindwing rounded off with an oblique distal margin, at the anal angle not lobate. Posterior tibiae with long, slender spurs.

vulpina. **O. vulpina** Fldr. (190 g). Upper surface black, basally more brown, in the upper half of the distal margin lighter blackish-grey, with small white cellular and 3 discal spots, as well as 3 subapical dots; the larger proximal half of the hindwing is of a bright brownish red. Beneath duller blackish, on the hindwing with a white band from the middle of the costal margin to the anal angle; costal margin basally yellowish-white. Colombia.

194. Genus: **Chloeria** Mab.

Antennae and palpi as in *Oenides*. Apex of forewing prolonged, cell longer than in the preceding; distal margin above the anal angle concave; the middle radial vein rises almost from the same place as the lower; Distal margin of hindwing likewise somewhat concave and the anal angle lobate. Posterior tibiae only with terminal spurs.

psittacina. **Ch. psittacina** Fldr. (190 g, h). Above blackish-brown, on the forewing subapically lighter, above it with 4 small, very oblong hyaline spots, at the cell-end and below it with a very large, double hyaline spot and a greenish-yellow, semi-transparent, postdiscal spot on the hindwing; the submedian area of the forewing and the cell of the hindwing are greenish-yellow; fringes analwards white. Beneath the hindwing and a very large subapical spot of the forewing are yellowish-green, the hindwing with black veins, the cell in the lower half and the anal fold broad black. Colombia to South Peru.

195. Genus: **Thracides** Hbn.

The reverted antennal apex is very long. Hindwing at the anal angle very much prolonged, body very robust; middle tibiae in *phidon* spined, in the other species bare. The ♂ shows a long stigma extending from the rise of the upper median vein to the middle of the inner-marginal vein. Several species are without it.

phidon. **Th. phidon** Cr. (191 b). Above black, basally and on the body metallic bluish-green with 3 large, white, discal hyaline spots and sometimes a small submedian spot. Beneath red-brown, base of costal margin on the forewing and base of hindwing white; the discal spots of the forewing are broadly connected with the white anal area. Panama to Colombia, Guiana, Brazil.

peratha. **Th. peratha** Plötz (191 b) is above almost quite metallic greenish-blue, on the forewing with a very large, bipartite discal spot, the lower distal apex of which almost touches the margin. Beneath somewhat lighter more brownish, the anal part of the forewing broad white, the cell bluish-green, palpi beneath dark ferruginous-brown. Bahia.

luda. **Th. luda** Hew. (= *hundurensis* Mab., *nealus* Plötz) (191 c) has no stigma; the blue is less bright, the cellular spot large and double. Body beneath and legs beneath darker. Honduras to Guiana.

molion. **Th. molion** G. & S. (191 b, c) has only 2 spots, one in the cell and one between the median veins, the submedian one being absent; below the apex there are 2 small subapical dots. The under surface is lighter, the anal angle of the forewing light, the hindwing is whitish at the base of the costal margin. Mexico.

bajula. **Th. bajula** Schs. Coloured as *molion* (191 b, c), with 2 semi-transparent white spots, that in the cell being distally gnawed out, parted by a fine line, the second extending below the cell-end to below the lower median vein, being prolonged below the latter to the distal margin. Base of hindwing with metallic blue hair. Beneath brown, the basal third of the costal margin of the forewing white, at the base with some metallic blue scales, at the apex strewn with yellow; at the anal angle there is a large white spot. Hindwing in the basal third of the costal margin white. Expanse of wings: 41 mm. Novo Friburgo.

phidonides. **Th. phidonides** Mab. is perhaps only a form of *molion* (191 b, c) and resembles *bajula* from which it differs by the presence of 3 subapical dots. Beneath there is a bluish-white dot below the white costal margin of the hindwing. Ecuador.

joannisii. **Th. joannisii** Mab. (191 c). The jet-black wings show a metallic greenish-blue reflection, distally to the scent-stripe with 3 hyaline white postdiscal spots in a straight line, the stigma itself being whitish, bordered with black and tripartite. Beneath the wings are suffused with purple at the apex, costal margin and disc of the forewing as well as in the disc of the hindwing, whereas here the costal and proximal margins remain black. Fringes white. Described according to a ♂ from Panama (Chiriqui).

panimeron. **Th. panimeron** Drc. is above uni-coloured deep indigo-blue, in an oblique light in the inner-marginal part of the forewing and the basal half of the hindwing metallic ultramarine-blue and opalescent green. Fringes white, towards the apex brownish. Beneath dark greenish-indigo, apex of forewing, and the hindwing with copper-reddish scales. Proximal margin of forewing brown, in the cell a metallic blue stripe; at the base of

the median a greyish-brown, black-haired scale-stripe. Palpi and collar reddish-orange. From Bolivia (La Paz).

Th. cincia *Hew.* (191 c) resembles *molion* (191 b, c), but it is much darker and duller blue at the *cincia*, base, and the costal margin of the hindwing beneath is not white at the base; the ♂ exhibits long hair below the submedian.

Th. braescia *Hew.* is also very much like *molion*, but the bases of the wings are quite brown, without *braescia*, any blue nor subapical dots. Pará.

Th. uridon *Dyar* is above black, on the body and bases of the wings bright metallic blue; forewing *uridon*, with a white, distally pointed cellular spot. Beneath dark greyish-brown, the costal margins of both wings basally white, on the forewing an oblique white band, widened below, the ground-colour before and behind it darker; a subapical, bent, dark shade. Hindwing with bent dark median and postmedian bands. Expanse of wings: 49 mm. Mexico (Guerrero).

Th. hyas *Mab.* is above brown, at the thorax and bases of the wings metallic blue; the forewing *hyas*, shows 4 white hyaline spots beside the long scent-stripe: 2 dots in the cell end at the opposite edge each, two medium sized spots behind it, and a subapical dot. Fringes dirty yellow. Under surface red-brown, at the apex and distal margin of the forewing lilac; below the apex there is a brown band extending down to the lower median vein. The hindwing is lilac with 2 red-brown bands, one at the costal margin, the second in the middle; proximal margin and fringes are yellow. Expanse of wings: 43 mm. Cauca Valley.

Th. cilissa *Hew.* (191 c). Above black, body, basal half of forewing and almost the whole hindwing *cilissa*, metallic bluish-green; the forewing exhibits in the ♀ 3 white discal spots, in the ♂ only 2. Beneath light red-brown, the anal part of the forewing very broad white, the cell green. On the hindwing several green spots arranged band-like. Amazon.

Th. nanea *Hew.* (191 d as *nannea*) is above similar though much darker, the spots of the forewing *nanea*, smaller, hindwing without any green. Beneath the inner-marginal part of the forewing and the whole hindwing are deep blackish-brown with a violet reflection, almost without any marking; cell of forewing and the space behind it deep metallic greenish-blue. Palpi below orange. From Maranhão.

Th. henricus *Stgr.* (= *mardonius* *Mschlr.*) (191 d) is above without any discal spots, uni-coloured *henricus*, blackish-brown with a blue body and base of the wings. Beneath brown, the forewing at the anal angle yellowish, the hindwing at the distal margin broad bright orange, the fringes ochreous. Panama.

Th. aroma *Hew.* (191 d) is above like *henricus*, but the fringes are grey. Beneath the forewing is *aroma*, broad whitish at the anal angle. The costal area is greenish-blue in the basal two thirds. Hindwing in the disc with a dark transverse band. Costa Rica to the Amazon.

Th. seron *G. & S.* (= *saron* *Mab.*) (191 d) shows on the dark brown upper surface 2 oblique post-*seron*, discal spots, the cellular spot is absent. Beneath besides with a submedian spot. Hindwing monotonously brown, at the base green. Fringes ochreous-yellow. Honduras.

Th. aurifer *G. & S.* (191 d). Above blackish-brown with a grey stigma. Forewing in the distal *aurifer*, half steel-blue with a double cellular spot and 3 large white postdiscal spots, above them 2 small ones and angularly to them 3 subapical ones. Under surface red-brown, forewing spotted as above; hindwing with 7 golden spots: one in the cell-end and 6 in a row behind it; the proximal margin is ferruginous-brown, the eyes are bordered with red-brown. Costa Rica.

Th. theodora *Ehrm.* we only place here on account of a certain resemblance to *aurifer*; it is described *theodora*, as a „Pamphila“. Chestnut-brown with 6 yellowish subapical spots and 2 cellular hyaline spots, the upper being triangular, the lower quadrangular; a submedian, brownish, longitudinal patch, above it a golden yellow spot. Hindwing with 7 golden, oblong spots from the apex to the proximal margin. Fringes light yellow. Beneath as above, but instead of the subapical spots there is a broad white band tinted red-brown at both its ends; anal angle dirty white. Hindwing subcostally white, in the cell a black spot, instead of the golden spots a broad white band; anal part reddish-white. Expanse of wings: 48 mm. Venezuela (Suapure).

Th. polles *G. & S.* (191 e). Brown; on the median of the forewing a narrow cellular spot, 3 larger *polles*, ones obliquely behind it; 3 subapical, small, yellow hyaline spots. Under surface lighter, anal angle yellowish; hindwing grey with 3 indistinct, whitish discal spots. Nicaragua to Brazil.

Th. placens *Btlr.* (= *laurens* *Mab.*) (191 e). Above dark brown with a cellular spot and 4 behind *placens*, it, the uppermost being very small; 2 subapical small spots. Base of wings and the hindwing almost entirely ferruginous-brown. Beneath purple-brown, bases of the costal margin and of the hindwing broad yellowish white, the anal angle ferruginous-brown. Panama to Colombia.

Th. salius *Cr.* (= *antoninus* *Latr.*) (191 e, f) is distinguished by the light violet basal area of the *salius*, hindwing, which is concavely defined towards the broad, brown marginal area, in the latter there are 2 or 3 small light spots. From Mexico through the whole of South America to Argentina and Trinidad. — In f.

- matthiolus*. **matthiolus** *H.-Schüff.* (193 a) showing a more intensely green reflection the marginal area of the hindwing as well as the basal area are darkened blackish-grey, both scarcely contrasting with each other. Colombia.
- longirostris*. **Th. longirostris** *Sepp* (= *telegonus* *Hbn.*) (191 f) resembles *salius*; the cellular spot is much larger, C-shaped, the spot of the hindwing just as variable as in *salius* and it may disappear altogether. Very common from Mexico to Brazil and in Trinidad.
- orusca*. **Th. orusca** *Schs.* is above dark brown with a small semi-hyaline cellular spot, a quadrangular submedian spot, a large, oblique one between the median veins and 3 smaller spots above it; 3 subcostal punctiform spots; on the hindwing a subapical row of 3 yellowish-white spots. Beneath the forewing is brown, at the proximal margin grey, in the basal half of the costal margin Isabel-coloured; before the small subapical spots there is a reddish-brown spot, the apex is parted by a lilac stripe. The hindwing is at the base and proximal margin broad lilac, the basal part bordered by a light, inwardly curved line; costal margin apically olive-brown; before the proximal margin as far as the anal angle is a light brown area. Expanse of wings: 40 mm. Petropolis.
- hermesia*. **Th. hermesia** *Hew.* (191 e) is undoubtedly a distinct species, in which the anal angle of the hindwing is more extended in a flap-like fashion. On the hindwing beneath the light yellowish-brown basal part very gradually, without a distinct delimitation, passes over into the violettish-brown marginal part in which there are 1 or 2 small light spots. Ecuador, Colombia.
- fischeri*. **Th. fischeri** *Hew.* (191 f) is likewise a good species. Above little different from the preceding; the hairing of the body and of the bases of the wings is olive-brown; fringes of hindwing whitish. Beneath the costal margin and apical half of the forewing, as well as the hindwing with the exception of the anal angle, are of a peculiarly dull bluish-green with fine dark veins and thereby not to be mistaken for any other species. Colombia, Rio de Janeiro.
- chiomara*. **Th. chiomara** *Hew.* (191 f) resembles *salius* (191 e, f), but it differs by the apex and costal margin of the forewing and hindwing beneath being reddish-brown except the anal angle. Panama to the Amazon.
- nanneta*. **Th. nanneta** *Plötz* (191 e) is above brownish-black with 2 white cellular spots, 2 larger quadrangular spots below and behind them, and 3 small subapical spots. The hindwing also exhibits 2 white spots behind the lower cell-end. Beneath the same, but at the costal margin and apex of the forewing and in the marginal area of the hindwing reddish-brown. Rio de Janeiro.
- lesueuri*. **Th. lesueuri** *Latr.* (= *caesena* *Plötz*) (191 f) differs above by a submedian spot of the forewing and only one postdiscal dot of the hindwing which, however, shows another one in the cell. Beneath on the hindwing the apical half of the distal margin is lighter violettish-brown. Brazil.
- haworthiana*. **Th. haworthiana** *Swsn.* (190 h). Above almost like *O. cynisca* (190 f), but on the body and bases of the wings deep metallic green and of a different shape of the wings. Beneath lighter, more violettish-brown; hindwing darker with 2 green transverse stripes converging somewhat towards the anal angle. From Brazil, apparently very rare.
- ethoda*. **Th. ethoda** *Hew.* (190 h) is a very conspicuous insect; basal halves of the wings and fringes orange-brown, discal spots very large, yellow, also the hindwing with 3 postdiscal spots and one cellular spot. Beneath on the apically orange-brown hindwing there is a very broad, silvery white longitudinal band. Rio de Janeiro.
- biseria*. **Th. biseria** *Schs.* Above dark brown with a long, light grey scent-stripe on the submedian. In the cell of the forewing there is a double, long, hyaline white spot parted by a dark longitudinal line; below it a large one, a small, distally concave one above it, and 3 small subapical ones below the costal margin. Hindwing light ochreous-brown, costal margin broad violettish-brown; at the cell-end a small light spot, 3 postdiscal ones behind it. Beneath dark brown, forewing spotted as above; on the hindwing the spots are more distinct, in the disc strewn with violet. Expanse of wings: 37 mm. Trinidad.
- stupenda*. **Th. stupenda** *sp. nov.* (190 h). Above blackish-brown, hairing of the body and the base of the hindwing in a certain exposure to light with a green reflection. Beneath the bases of both wings are dark brown, on the forewing in the shape of a streak prolonged along the median and transverse vein; apical part somewhat lighter reddish-brown, between canary-coloured; on the hindwing 2 basal thirds are dark brown, the distal third being yellow; between the two colours in the disc of the wing 4 silvery white spots on the yellow ground; the middle of the distal margin is narrowly brownish. 1 ♂ from the Rio Aguaca (Colombian Western Cordilleras), taken at an altitude of 2000 m; in the Coll. FASSL.
- lotana*. **Th. lotana** *Btlr.* (193 a) is above purple-brown, towards the base blacker and haired greenish as on the body. Forewing with a white cellular spot, 3 postdiscal ones and 3 subapical ones, hindwing with 2 pale yellowish spots and yellow fringes. Beneath the distal margin of the forewing is lighter. The hindwing is yellow, at the base, costal-margin and a subapical costal-marginal spot black like the proximal and distal bordering of the hyaline spots; an antemarginal, blackish band. Amazon (Tocantins).
- xanthura*. **Th. xanthura** *G. & S.* (190 h) resembles *Rhithon anthracina* (185 h), but it has no scent-stripe, a longer antennal club and yellow anal-angular border of the hindwing; the yellow as of a very variable extent, changing from a narrow yellow marginal line to a large yellow anal spot. Under surface reddish-brown, the discal area of the forewing as far as the proximal margin blackish-brown, behind the cell tinted purple, the distal margin analwards narrowly yellow. The hindwing is in the middle of the cell broadly purple, at the distal margin and anal angle broadly yellow, the submedian fold striped blackish-brown; fringes of hindwings yellow. Honduras, Panama, Colombia.

196. Genus: **Alera** Mab.

Palpi and antennae as in *Thracides*. Apex of forewing somewhat stunted, distal margin running straight down to the middle radial vein, then very oblique to the anal angle; the two lower subcostal veins forked. Posterior tibiae with long hair.

A. furcata Mab. The very long, blackish-brown forewing shows in the middle an oblique band of *furcata*, 4 hyaline spots: the first at the costal margin yellow, the 3 others white; behind the lower cell-angle there is a smaller one, farther distally; fringes brown. Hindwing without spots, with yellowish fringes. Base of forewing beneath blackish, apex lilac-white. Hindwing at the base greyish-yellow, otherwise brownish-violet with a lighter part at the distal margin. Body above metallic blue. Expanse of wings: 56 mm. São Paulo.

197. Genus: **Perichares** Scddr.

Antennae long with a very long club and very long apex. Veins not different from the usual veins. Hindwing prolonged at the anal angle. Body strong; middle tibiae with short spines. The ♂ exhibits a strong scent-scale stripe from the rise of the upper median vein to the middle of the submedian.

P. corydon F. (= phocion F., dolores Reak., adela Hew., marmorata Scddr.) (192 a). This very *corydon*, common and widely distributed species is above brown with yellow hyaline spots, and beneath in the apical part of the forewing and on the hindwing marbled lilac; fringes distinctly speckled. Abdominal end beneath ochreous-yellow. From Mexico to Brazil, in the Antilles, Cuba, Jamaica, Hayti.

P. tripuncta sp. nov. (191 g) is above dark brown, at the cell-end above the median a narrow hyaline *tripuncta*, spot, below it and distally to it a V-shaped one, above it another small, quadrangular one. Beneath somewhat lighter, hindwing brown without any markings. Described according to 3 ♂♂ in the Coll. SEITZ from Honduras and Southern Brazil.

P. heroni Kaye. Above deep chocolate-brown, at the apex of the forewing narrowly white; in the *heroni*, cell a yellow spot strangled in the middle, below it 2 wedge-shaped spots; behind the cell-end another small, yellow, punctiform spot. Beneath the apex of the forewing and the costal margin are reddish-lilac, the rest dull black with the yellow spots. Hindwing reddish, suffused with brown, with 2 small yellow postdiscal dots. Expanse of wings: 48 mm. Trinidad.

P. trinidad Luc. (192 a) differs so much from *corydon* (192 a) with which it was confounded, that *trinidad*, we must better consider it to be a distinct species, at least as an especial insular form (from Cuba). From *corydon* it differs by only 3 spots of the forewing, a hook-like bent spot in the cell and 2 behind it. Fringes speckled; beneath not different from *corydon*.

P. agrippa G. & S. (191 g) is blackish-brown, at the base green, the stigma grey; 3 postdiscal white- *agrippa*, hyaline spots, a transverse one between the median veins and a smaller one behind it, before it in the cell a long, oblique, curved spot. Beneath somewhat lighter, costal margin of forewing apically lighter whitish; hindwing scantily dusted with grey, fringes ochreous. Nicaragua.

P. lotus Btlr. (192 a). The ♂ is blackish-brown, fringes of hindwings whitish ochreous. Body and *lotus*, bases of wings green; in the cell of the forewing there is a large, yellowish, distally concave spot, a triangular spot behind it, stigma grey. Beneath the same, apex of forewing, and hindwing marbled lilac-grey. The , has white spots, beside the cellular spot a large one between the median veins and one small spot each below and above it. Mexico, Panama, Colombia, Venezuela, Ecuador, Trinidad.

P. lusciniæ Plötz (192 c) resembles *corydon* (192 a), but differs by the absence of the white spot of *lusciniæ*, the forewing above the submedian and by the hindwing beneath, where the dark spots flow together forming transverse shades which rest almost rectangularly on the submedian fold. South Brazil, known from the Colony of Blumenau in Sa. Catharina.

P. lindigiana Fldr. (= colenda Plötz) (191 f) is very easily recognizable by the broad orange proximal *lindigiana*, margin and anal angle of the hindwing. Forewing with 3 large white discal spots which are beneath prolonged to the costal margin. Apex of forewing, costal margin, and the hindwing lilac, mixed with brownish, with 3 brown transverse bands and a broad similar marginal band. Fringes of hindwing at the apical part yellowish-white. From Colombia and Venezuela.

P. crotona Hew. (= elisa Plötz) (191 g) has above 2 very large yellow discal spots and one smaller *crotona*, one, which are situate close together; above the submedian there is mostly yet a yellowish longitudinal patch which turns a large white spot on the under surface, extending almost to the proximal angle. Hindwing violet with large brown spots and a broad brown margin. Colombia, Brazil.

P. anitta Plötz (192 c) is rather similar to *corydon* (192 a) above, but in the apical part of the forewing *anitta*, there are 5 or 6 minute hyaline spots. Beneath the hindwing is uniformly coloured lilac-grey, only the cell and anal lobe are filled up with dark brown and before the margin are some narrow, small internerval spots. From Brazil.

butus. **P. butus** Plötz (192 b) is blackish-brown, towards the base and on the body green, with a small yellow cellular spot, a subapical spot and one behind the lower cell-angle. Beneath the hindwing is dark green with black dentate bands and spots, at the distal margin and proximal margin violettish-grey; on the forewing the cellular spot is enlarged and there is a green spot before the subapical spot. From Surinam.

tripлага. **P. tripлага** Schs. is above dark brown, on the body and bases of the wings metallic dark-blue; in the cell of the forewing there is a quadrangular, hyaline yellow spot, a triangular one between the median veins and a smaller quadrangular one above it; fringes at the anal angle yellowish. Hindwing unmarked with yellow fringes being dark brown at the anal angle. Beneath the same, above the cellular spot there is a yellow costal-marginal one; from the cell-end to the apex dusted with lilac. Hindwing at the costal margin, base and two thirds of the proximal margin light brownish, behind it dark brown, growing lighter towards the distal margin, before the margin with a lilac nebulous band. Expanse of wings: 49 mm. Castro (Paraná).

198. Genus: **Talides** Hbn.

Distinguished from *Perichares* by the broader, round shape of the wings, on the forewing a less oblique discocellular. Stigma the same, very distinctly developed.

sergestus. **T. sergestus** Clerck (= sinon Cr.) (192 b). Above dark brown, on the body and wings basally haired ochreous. Forewing with a cellular spot, 3 postdiscal and 3 subapical spots; hindwing with a small, round hyaline spot behind the cell; fringes orange-ochreous. Under surface suffused with red-brown, analwards on the hindwing before the fringes narrowly orange. The ♀ has much larger spots and one submedian spot besides, which may occasionally also occur in the ♂. — f. **adjunctus** Plötz (192 d) is above and beneath much darker. Mexico to Brazil and Trinidad.

199. Genus: **Pseudosarbia** Berg.

As the name indicates, the genus contains exact copies of the genus *Sarbia* Wts., from which, however, it is separated by the veins and very distinctly by the structure of the antenna the club of which is not reverted like a hook, but stretched forward like a fusiform knob. The larvae are quite different, too. All the species known live in Brazil and Argentina.

phaenicola. **P. phaenicola** Berg. (193 a) is such a true copy of *Sarbia pertyi* or *spixii* (164 f) flying in the same district that it is impossible to distinguish them in the open air. Both species have the same size, red ends of the bodies and the yellow, Y-shaped macular bands in the forewings. They chiefly differ by the patagia showing in the *Sarbia* a lemon-coloured, in the *Pseudosarbia* a red middle streak. Besides *phaenicola* has the head and collar as scarlet as *Sarbia*, but the end of the abdomen is decidedly fiery red or miniate. — The larva is unicoloured green, also the head which shows a shaggily yellowish-green haired face. The thoracal segments of the larva are also bristly haired. South Brazil and Argentina.

elana. **P. elana** Plötz (192 b as *elanus*). Above black with white fringes, a tripartite discal spot and a quinquepartite subapical spot of the forewing and a white postdiscal band of the hindwing; apex of abdomen white. Beneath the same, but the hindwing shows yet a yellow longitudinal band above the median, and the discal spot of the forewing is continued yellow to the costal margin. From Brazil (Chapada).

mitella. **P. mitella** Plötz (192 c) is very much like *elana*, smaller, of a more brownish ground-colour; fringes and the band on the hindwing are more yellowish, the latter beneath quite yellow and continued almost equally broad to the costal margin; the yellow longitudinal ray is absent. Apex of abdomen beneath ochreous-yellow. Brazil (Chapada).

200. Genus: **Pyrrhopygopsis** G. & S.

Antennae and palpi shaped as in *Perichares*. Cell of forewing attaining not quite two thirds of the length of the forewing; the middle radial vein at the base very much bent down and rising near the lower one. The genus is placed to the *Hesperinae* by MABILLE, but as the authors quite correctly recognized, undoubtedly belong to the *Pamphilinae* in the propinquity of *Thracides* and *Perichares*. In the exterior some species entirely resemble the *Pyrrhopyge* (p. 837—840, t. 162) from which they are immediately discernible by the antennae.

socrates. **P. socrates** Mén. (165 b, c) entirely resembles a *Pyrrhopyge*, above black with white fringes; head and anus red. Beneath the apical half of the forewing and the larger costal-marginal half of the hindwing except the black inner-marginal part are bronze-green with black veins. Brazil.

oratus. **P. oratus** Drc. (= *aviola* Mab., *socrates* Stgr.) (165 c) is above lustrous steel-black; beneath like *socrates*, but the basal area of the hindwing broad white. Head, palpi and anus red, fringes white. Panama to Peru.

P. igniculus *Drc.* is closely allied to the preceding species from which it differs by the reduction of the white basal area on the hindwing beneath, consisting only of a white spot above the costal vein and some white scales at the lower edge of the cell. From Peru (Pozuzo).

P. caninus *Drc.* is likewise closely allied to *oratus* (165 c), but coloured lighter, with a white border of the hindwing before the white fringes. Beneath the costal margin is white from the base to behind the middle of the cell. Head, palpi and apex of abdomen red, like the anterior hips and pectoral hair-tufts. Colombia (Rio Meta).

P. tenebricosa *Hew.* (165 c) likewise greatly resembles the preceding; above coloured the same as the preceding. Beneath of a more yellowish tint, with a yellowish basal area of the hindwing as far as the cell-end, gradually passing over into the bronze-green tint, being not so distinctly defined as in *oratus* (165 c). Shoulders red-brown. Peru.

P. lugubris *Drc.* Above uni-coloured jet-black with white fringes which, towards the apex on both wings and at the anal angle of the hindwing, are smoked grey. Beneath both wings are dark green, with black veins, the proximal margins on both wings blackish brown. Head, palpi and legs are black, posterior tibiae and sides of the chest with red-brown hair-tufts, abdominal end likewise red-brown. Bolivia (La Paz).

P. subvirescens *Schs.* Above bluish-black, fringes of the forewing apically brown, analwards whitish, fringes of the hindwing yellow. Beneath olive-green, with black veins, on the forewing the lower half of the cell and the proximal margin as far as the upper median vein are bluish-black, on the hindwing the inner-marginal part. Palpi red except the black terminal joint; the last 3 abdominal rings and the anus are red. Expanse of wings: 43 mm. Castro (Paraná).

P. quispica *Plötz* (= *reedii* *Weeks*) (165 c) differs from the preceding by the ground-colour above being more brownish-black, and the fringes orange-red or yellow. Beneath as *socrates* (165 b, c). Peru and Bolivia.

P. camposa *Plötz* (166 b, c) is above greenish steel-blue with whitish fringes and red anus. The under surface is of a bright green, the costal margin of the forewing yellow, the proximal part black; the middle of the hindwing is crossed by a broad black band, the inner-marginal part is likewise broad black, towards the base with a green spot in it. Brazil.

P. maraviha *Foetterle* (165 b as *camposa*) very much resembles *camposa*, but easily discernible by red shoulder-covers and beneath by the absence of the yellow costal stripe of the forewing; the colour of the hindwing is more golden yellow, and in the steel-blue inner-marginal part there are 2 oblong spots of the ground-colour. South Brazil.

P. cleantes *Latr.* (165 d as *cleanthus*). Above steel-black with 2 white discal spots, and on the hindwing white fringes being red at the anal angle. — f. **apicalis** *H.-Schäff.* is only a form of it with very small spots. Brazil. — f. **romula** *Drc.* (165 d) probably also belongs hereto and has larger, confluent, white discal spots. Colombia.

P. telmela *Hew.* (192 c) has a much more extensive white discal band, since beside the spots of the preceding there are yet a quadrangular cellular spot and a submedian spot; in addition often yet a distally remote 5th spot and a subapical one; these forms belong to f. **ochrope** *Plötz*. Brazil (Pará).

P. xanthothrix *Mab.* Sooty black with a violet reflection, forewing at the base lighter. Fringes yellow, at the apex of the forewing and anal angle of the hindwing blackish. Under surface as in the following *agaricon*. Shoulders anteriorly bordered with red, bases of palpi spotted red; the two last abdominal rings are margined with red, abdomen laterally spotted red. Expanse of wings: 50 mm. Peru (Hunyabamba).

P. agaricon *Drc.* (161 a) is above dark purple-brown, body and basal third on both wings tan-coloured. Beneath golden lustrous olive-green, with black veins, in the proximal part of the forewing and at the proximal margin of the hindwing brownish-black. Colombia.

5. Subfamily: Megathyminae *Mab.*

We append here this group of very much deviating species to the Hesperids, in order not to conflict with the opinions expressed in the works we have hitherto followed in general (especially *MABILLE's* Catalogue of the Hesperids and *WYTSMAN's* Genera Insectorum), which might prejudice the utility of both works. We remark, however, that the *Megathyminae* have, especially of late, been often quite correctly regarded as a separate family. A work as the „Macrolepidoptera of the Earth“, serving essentially a practical use has its main point more distinctly there where the single groups are to be inserted than in the rank that may be attributed to the single groups. We therefore do not try to correct *MABILLE*.

The head of the *Megathyminae* is much smaller than otherwise in the Hesperids. Antennae thick and fixed with a stout club and a very short point on it. Body long and stout. Middle and posterior tibiae with a pair of very short terminal spurs. Veins as in the last genera: the middle radial vein of the forewing at the base very much bent downward and nearing the lower. Peculiar, hairy insects externally reminding us of the *Castaia*. The larvae, as far as they are known, live in the interior of plants.

1. Genus: **Aegiale** Fldr. *Acentrocne* Scddr.

From the following genus only separated by 3 insignificant, morphological differences: the so-called *pulvillus* or „cushion“ on the ventral side of the last tarsal joint is strongly developed, forming a globular convexity. The 2nd palpal joint is long and uniformly narrow, the 3rd very short, conical, somewhat pointed; the basal covering of the palps consists of large, triangular scales, being towards the apex entirely covered by the long, rough hairing. On the ♂ forewing the upper median vein is at its base not bent down and nearing the lower. Only 1 species:

hesperiaris. **A. hesperiaris** Wkr. (= *kollari* Fldr., *agavis* Blasquirt) (193 c) is a large, monstrous insect very much like a *Castnia*. Above light fox-coloured, postdiscally somewhat paler with 3 whitish subapical hyaline spots, a black marginal band, postmedian subcostal spots and a dentate antemedian oblique band; hindwing with a blackish-brown border, an indistinct nebulous band at the cell-end. Beneath the hindwing is grey, with thick whitish hair and 2 or 3 indistinct blackish dentate lines; forewing lighter yellow than above. Mexico. The larva lives in the stalk of Agaves and is eaten by the Indians.

2. Genus: **Megathymus** Scddr.

The genus contains somewhat smaller, not so monstrous species. The wings in several species are covered with hair partly standing vertically on the surface of the wings. The *pulvillus* is not developed, only forming a short, conical projection between the terminal claws. The 2nd palpal joint is short and obtuse, the terminal joint not conical, obtusely rounded off; the scaling of the palpi is only intermixed with few hairs. The upper median vein is in the ♂♂ very much bent downward at the base and nearing the lower. The ♂♂ fly wildly and timidly about in the hot sunshine on sandy, hot places.

neumoegeni. **M. neumoeni** Edw. (= *aryxna* Skinn.) (193 b) above entirely resembles *cofaqui*, but on the forewing it exhibits yet a spot above the middle of the submedian, and instead of the marginal band a more proximally removed antemarginal band. Beneath the same, though greyer. Arizona, South California to Mexico. — f. *stephensi*. **stephensi** Skinner is above greyer in the colour, the yellow spots are distinct, especially the cellular spot. California.

aryxna. **M. aryxna** Dyar is extremely similar to the preceding and often also only differs by variable characters, so that only a precise examination of the genitals affords a guarantee: the distal valval end is shorter and obtuser than in *neumoegeni*, the processus basalis at the beginning much broader, the distal spining of the penis quite different, consisting only of 3 or 4 minute teeth at the distal edge, in *neumoegeni* on each side with a row of 5 or 6 teeth. *aryxna* is generally much larger, the spots are mostly larger, flown together to a band, the 2nd spot from the the proximal angle is proximally wedge-shaped; the yellow basal hairing is much less extensive; the under surface of the hindwings is darker, less abundantly strewn with white. From South Arizona.

polingi. **M. polingi** Skinner looks quite different, more like *A. hesperiaris* (193 c) and is above bright orange-brown with a black distal margin being broader at the apex, a large black subapical spot and a large, irregular discal spot. Hindwing bordered with black, before it with a broad, orange-brown band not quite reaching to the costal margin nor to the proximal margin. Basal areas of both wings orange-brown. Beneath the yellow colour is subapically whitish. The hindwing is grey with an irregular whitish band parallel to the costal and distal margins; in the middle of the wing 2 whitish spots, the lower being much larger. Expanse of wings: 44 mm. Arizona.

yuccae. **M. yuccae** Bsd. & Lec. (193 c, d) is a larger species; above brown, basally more intensely haired olive, with a yellow cellular spot and a band of 3 spots being removed far towards the margin and analwards; 3 or 4 subapical and farther distally below them 2 more whitish hyaline spots. In the ♀ the postdiscal band is much broader and united with the cellular spot, with another submedian spot, and the hindwing shows a yellow postdiscal band. Fringes of forewings grey, of hindwings yellow, speckled darker. Beneath more grey, on the forewing apically and the whole hindwing strewn lighter, the hindwing with a large, light costal-marginal and anal-angular spot. South Carolina, Georgia, Florida. — The larva is bone-coloured with a lighter lateral and greenish dorsal stripe; it lives in Yucca and changes in an inwardly white-spun cocoon into a white pupa. — f. *coloradensis* Streck. (= *navajo* Skinn.) is a scarcely different, smaller, less dark form from Texas, Colorado, Arizona.

cofaqui. **M. cofaqui** Streck. (193 b) is easily distinguished from *yuccae* by a much broader, yellow discal band cohering with the costal spot, by a short, squat shape of the wings, and by 4 white spots on the hindwing beneath which is strewn with grey, one at the anal angle, 2 at the costal margin and one in the cell. Hitherto only one ♀ seems to be known. Georgia; Florida.

ursus. **M. ursus** Poling seems hitherto only to be known in 2 specimens. Above brown with 3 yellowish-white subcostal spots and a band of 5 large orange spots from here to the proximal margin and a similar spot

near the cell-end. Hindwing without spots, with white fringes. Beneath the hindwing shows 2 white costal-marginal spots and 4 more in one line behind the middle. South Arizona (Pina County).

M. streckeri *Skinner* is very much like the preceding *ursus*, but of a black ground-colour and the *streckeri*. marginal band of the hindwing is absent. Colorado, New Mexico, Arizona. — f. **texana** *Barn. & Mc D.* (= *cofa- texana*, *qui auct.*) from South Texas differs little, the ground-colour being browner, the spots more orange-yellow and smaller.

M. smithi *Drc.* is above dark brown with light yellow spots, one in the cell-end, 3 subapical ones *smithi*. and a submarginal row of small spots as far as the proximal angle with brown and light yellow speckled fringes. The hindwing also shows a submarginal row of indistinct yellow spots, the fringes being here white. Hindwing beneath brown, at the proximal margin grey with 2 white zigzag lines from the costal margin to the proximal margin. Texas and Mexico (Guerrero).

M. indecisa *Btlr. & Drc.* (193 b). Above blackish-brown, towards the base with olive-brown hair, *indecisa*. and ochreous spots as in *neumoegeni*. Fringes whitish, speckled dark. Beneath apically and on the hindwing strewn with grey. Mexico, Costa Rica, Panama.

M. rethon *Dyar* (193 b, c). Black with a steel-blue reflection, on the forewing with but one minute *rethon*. white subapical spot, otherwise without marking. Fringes speckled white and black; hindwing from the direction of the distal margin somewhat bordered with white. Beneath the same, but with 3 minute subapical spots; hindwing strewn with grey, especially submarginally in the shape of small spots and at the margin itself which is separated from the fringes by a black marginal line which is not visible above. The ♀ has above in the cell-end a small light yellow spot and traces of a lighter, yellowish postdiscal band. Expanse of wings: 50 mm. Mexico (Guerrero).

Additions to Vol. V.

Papilionidae.

Having transferred the newly described forms since the publication of the work to the supplementary numbers, we add here some statements about the *Papilio* which have been dealt with on p. 12 to 44 of this volume.

P. ascanius (p. 12). The larva is blackish-brown, powdered with grey, which is on the dorsum condensed into fine markings. The fleshy cones are very dark red, some (in front and behind on the larva) pale yellow. It takes the species from its oviform state 3 to 4 months to develop into the imago. (FERREIRA D'ALMEIDA).

P. perrhebus damocrates (p. 13). Larva stout, dark earth-coloured brown, the fleshy cones changing from yellow to red-brown; some of these cones, as well as an oblique band extending from the foremost ventral feet towards the dorsum, bone-coloured. On *Aristolochiae*, *Asarum* etc. Pupa with a widened abdominal part, an obtusely bituberculate head, green. I very frequently captured the imagines at the end of January and in February on blue-blossoming bushes in the Agricultural Park of Palermo near Buenos Ayres.

P. agavus (p. 13). According to FERREIRA D'ALMEIDA, the dull or lighter purple eggs are deposited on the leaves of *Aristolochia rumifolia*; larva in its adult stage similar to that of *nephalion*, reddish-brown finely dusted with a yellowish ashy brown, so that irregular markings across the dorsum are produced; with numerous red-brown, on the 2nd, 7th and 10th rings yellow fleshy cones across the dorsum and similar ones laterally, of which those on the 1st, 6th and 10th rings are yellow. A yellow lateral band ends at the dorsal cone of the 7th ring. Pupa green with a grey (ventrum) or yellow (dorsum) tint. The imago, though living in the forests, frequents also gardens on account of the food-plant; it flies singly all the year round, but near Rio it is of frequent occurrence especially from November till January and from May till September.

P. quadratus (p. 14; ♂ t. 2 b). In the meantime the ♀ has also been communicated by A. H. FASSL. The length of the forewings is 33 mm, and thus it is one of the largest ♀♀ of the *aeneas*-group. The white square spot is about twice as large in both the specimens taken, as in the ♂. The upper surface of the ♂ is much darker than in the ♀ of the form *spoliatus* Stgr.; the distal half of the forewing somewhat lighter, the black veins in it well visible; along the costa of the forewing beneath runs a greyish-white longitudinal patch extending almost into the apex. Hindwing with a roundish, undivided, yellowish-white discal spot about twice as large as in the ♂. Red oval spots of the dorsal side of the hindwing likewise present, somewhat lighter red and larger than in the ♂; the same is the case with the red collar and the red spots, beneath on the chest and anus. — Also all the ♂♂ captured quite constantly exhibit the square angular spot of the forewing, to which the species owes its denomination.

unimacula. *P. childrenae unimacula* J. & T. This form originates from Ecuador. From the typical *childrenae* the ♂♂ differ by a reduction of the green cellular stripe on the forewing; on the hindwing the red longitudinal spot is shorter and ends more remote from the margin. The ♀ forewing exhibits a single light spot behind the middle of the submedian space. On the hindwing the red colour is very much reduced.

dilutus. *P. cutorina dilutus* J. & T. from Ecuador is based upon a ♂ which is of a smaller than normal size and has shorter spots on the hindwing, the distal spot being pale pink.

P. nephalion (p. 18). The orange eggs are deposited on *Aristolochia brasiliensis*; the imagines fly in Southern Brazil particularly from January till May and from the end of August till December. (FERREIRA D'ALMEIDA).

P. zacynthos (p. 19). Larva dark brown, covered with grey, the light colouring being arranged into longitudinal strokes. The fleshy cones are anteriorly and posteriorly light yellow, on the middle rings mostly reddish-brown. The species, according to FERREIRA D'ALMEIDA, has up to 5 generations a year near Rio. Pupa similar to that of *P. agavus*; the eggs are singly deposited on *Aristolochia rumifolia* oblonga.

P. polydamas (p. 20) flies all the year round in South Brazil, but more frequently in May and October till December; the eggs are not singly deposited, but mostly some at one place or near *Aristolochia brasiliensis*. (FERREIRA D'ALMEIDA.)

P. polystictus (p. 21). According to FERREIRA D'ALMEIDA the larva of the form *janira* is grey, tinted yellowish, the fleshy cones are red, tinted dark; it flies more on grassy plains, not on marshy soil, as most of the other lepidoptera feeding on *Aristolochiae*.

P. lycidas. Specimens from Ecuador, in which the bone-coloured subcostal spot of the hindwing is joined by a series of some more minute internerval spots, were named **adlatus** Niep. — A corresponding form of *belus*, exhibiting such small internerval spots of an orange colour, the occurrence of which is mentioned already by JORDAN on p. 21, is named **chrysomaculatus** Niep. Ecuador. — Another *belus*-form is: **ingenuus** Dyar from Mexico. adlatus.
chrysomaculatus.
ingenuus.

P. zelicaon (p. 24). The larva may look almost exactly like that of *machaon*; but the black colour of the bands may also flow together in such a way that the green disappears almost entirely and that the larva then shows the thick red dots on an entirely black ground, like in *Parnass. apollo*.

P. lycophron v. **delunensis** is a form denominated by NIEPELT, in which the submarginal lunae of the hindwings are still more reduced than in *hippomedon* Fldr. Brazil. delunensis

P. androgeus (p. 26). FASSL bred on the Rio Xingu from larvae having been taken down from orange-trees, after a 100 days' pupal stage *androgeus*-♀♀, similar to those of *epidaurus* G. & S., which, however, did not show any trace of the yellow spot in the forewing; he denominated them **mira** Fassl. mira.

P. anchisiades (p. 28). The larva in its juvenile stage lives gregariously and only later on forms the well-known „mirrors“ of numerous larvae being crowded together on the trunks of orange-trees. In their adult stage they are greenish-brown with numerous chased-like, intertwined markings on the dorsum. Pupae brown, in front and behind often tinted greenish. According to FERREIRA D'ALMEIDA, the pupa in Southern Brazil often rests for 4 months, during the whole winter. — According to FRUHSTORFER (Entomol. Rundschau, 1915, p. 70), specimens from Trinidad (the island) exhibit enlarged white spots on the forewings, as large as in *chianisiades* (10 d), though removed more proximally. FRUHSTORFER introduces for it the name **philastrius**. philastrius.

P. hectorides (p. 29). Larva in its adult stage brownish with yellowish-brown and blackish markings and whitish, irregular lines and strokes; on the sides of the thoracal ring a light lateral band tinted yellowish or pink; in the shape similar to the larva of *thoas* (FERREIRA D'ALMEIDA). The imagines are particularly common near Rio in April and May and in August and September. Specimens from Paraguay (= **agordus** Fruhst.) show in the ♂ larger yellow crescents on the hindwing, whilst the ♀ has narrowed red crescents on the hindwing and a coherent white band on the forewing. — **lysirte** Fruhst. are specimens from Rio Grande do Sul and Sa. Catharina with a broader, mostly hued yellowish band on the ♀ forewing; in the hindwing also the white spots are larger. agordus.
lysirte.

P. zagreus (p. 31). Specimens from Pozuzo in Peru, according to FRUHSTORFER, differ from typical specimens from Colombia and Venezuela by the median spots being also in the costal part of the wing orange, not light yellow; the antimarginal spots are larger and lighter yellow (= **chrysoxanthus** Fruhst.). chrysoxanthus.

P. bachus **belsazar** Niep. 1 ♂ from Cuscari in Ecuador. From *bachus typicus* chiefly different by the yellow spots filling up the radial spaces on the forewing being parted by dark embedments, and by the hindwing showing an orange band in front of the black marginal band. belsazar.

P. neyi Niep. resembles *zagreus* (11 c), but it has rounder forewings, in the apical half of which the bone-coloured spots are much larger than in *zagreus*; in the hindwing the dark spots being situate around the lower cell-wall are combined to a black cloud. Ecuador. neyi.

As the ♀ of *P. trapeza* R. & J. NIEPELT describes a specimen of this species from Ecuador, which, however, shows entirely male wing-contours (on the figure in „Lepidoptera Niepeltiana“ tab. XII) and according to JOICEY and TALBOT is also in fact a ♂ in which the light forewing and the red spot of the hindwing are somewhat reduced. The ♀ of *trapeza* being unknown to me is presumably on the contrary more variegated than the ♂. — **concoloratus** J. & T. are specimens from Balzapamba in Ecuador, in which both sexes are without the spot of the forewing. concoloratus.

P. bitias. As v. **marcus** Niep. a form is described with a more deeply dentate margin and a broader band of the hindwing beneath; from Pozuzo (Peru). marcus.

P. cacicus **peruviana** J. & T. approximates the form *inca* R. & J., but the reddish (in the nominal form bone-coloured) discal band shows the spots in the cell 2 and 3 prolonged as far as the cell. Of the post-discal spots only the lower ones form 5 small crescents, whilst the upper ones are only oblong, not sharply defined. It replaces the form *zaddachi* in Peru. Described according to 1 ♀ from La Merced. peruviana.

P. xynias **xisuthrus** Niep. The ♂ shows the red spot of the hindwing proximally prolonged; from Ecuador. NIEPELT figures as the ♀ of this form quite a similar lepidopteron with decidedly male wing-contours, in which the red spot of the hindwing is reduced to a faint trace at the proximal margin above the anal angle; this is presumably likewise a ♂. xisuthrus.

P. euryleon. A ♂ from Ecuador is described flying together with the form *anatmus* R. & J., which scarcely differs from it; the margin of the hindwing is strongly dentate, behind the cell 3 red spots, before the margin a row of narrow white spots. The greyish-green colour of the forewing is extensive. NIEPELT denominates this form **punctata**. punctata.

NIEPELT figures the ♀ of *harmodius xeniades* Hew. with longer red spots of the hindwings, being otherwise similar to the ♀ of *androna* (13 d). — As **jarbas** Niep. a ♀ is described with a large postmedian white discoidal spot of the forewing; from Ecuador. jarbas.

- gaesatus*. *P. ariarathes* **gaesatus** *Fruhst.* from Matto Grosso resembles the form *leuctra* from Goyaz, but the white demi-band on the proximal margin of the forewing as well as the red spots in the anal region of the hindwing are reduced.
- delunaris*. *P. turnus* ab. **delunaris** *Schultz* are specimens in which the yellow marginal lunae are almost dying away. — ab. **perfulva** *Schultz* are specimens with a dark yellow ground-colour. *delunaris* seems to correspond to the *machaon*-form *nigrofasciatus* *Rothke*, *perfulva* to ab. *aurantiaca*.
- subnigrata*. *P. eurymedon* ab. **subnigrata** *Schultz*. On the upper surface the light marginal spots are absent.
- lurida*. *P. cresphontes* ab. **lurida** *Schultz* has a creamy white instead of yellow ground-colour, and the light spots of the forewings are smaller.
- tockhorni*. *P. marcellus* ab. **tockhorni** *Oskar Schultz* denominated a specimen of the species with dull brownish-yellow and dull blackish bands. As in *marcellus* the ground-colour being in the living insect of a wonderful Nile-green invariably grows pale in the dead insect — the longer the more so —, this is probably a postmortal variation.
- anemos*. *P. dolicaon* **anemos** *Fruhst.* has the forewings like *deicoon* *Fldr.* from Paraguay and Southern Brazil, but the white subapical maculae are duller, the posterior part of the cell dusted with black; hindwing similar as in *deileon* *Fldr.*, but with a larger yellow subanal spot. From Matto Grosso.

Pieridae.

- suffusa*. *Neophasia menapia* **suffusa** *Wr.* is a more intensely marked form from the western coast of North America; especially the hindwing beneath shows broader markings of the veins and reddish marginal spots.

As to the most interesting biology of *Eucheira socialis* *Westw.* (18 a, 194 a) the following is known. „The small, bluish-white eggs are of an oblong shape and are deposited on the leaves of Madrono (*Arctostaphylos*); it has also been observed that the eggs were deposited within the larval nest, but this is only the case if the insects, for reasons explained farther below, could not find their way out of the nest. The larva is of a dark coffee-brown colour and clad with longitudinal rows of short soft hairs of white colour, which, however, are not nettle-hairs. The larva attains a length of 25 to 20 mm. Of the twelve not strongly marked segments the first thoracal ring and the anal segment are mostly somewhat darker. The head is black. The larvae feed at night and, like the processionary caterpillar, they come in the evening in long rows, one behind the other (not in double rows), out from their nest into which they return again towards the morning and where they spend the whole day. „The nest is a solid web, not unlike thick parchment which it resembles also in the colouring. It is about 20 cm long, of a somewhat oval shape, narrow at the apex which forms something like a neck and is fastened on a thin branch, without being able to swing to and fro, because it is built at the junction of two branches running along the neck of the nest. On the whole, this nest very much resembles those of French wasps, e. g. the wasp *Chartaria*. On making a longitudinal incision from the bottom of the nest, a peculiar sight is offered by no less than a hundred pupae being fastened at its interior upper surface on the upper half of the nest, as well as by the lower part of the branch passing through the neck of the nest. The size of the nest and the number of larvae and pupae therein are very variable. One may find small colonies of 4 to 6 specimens and then in all sizes with up to 100 occupants and more. The ingress is always at the deepest place of the nest towards the soil. This is of the greatest importance for the hygienic conditions of the colonies, since on the one hand the dead insects and excrements can easily fall out of the nest, and on the other hand dampness and rain cannot enter, so that in this way the mildew diseases spreading havoc among the larvae are avoided. There are often also bags found with two entrances.

HUMBOLDT denotes these larval nests of *Eucheira socialis* as „natural paper, and they have indeed also been used by the Aztecs as paper before the Spanish Conquest.

One question had not been cleared up to the present day: in what way the developed imago is able to get out through the narrow opening of the nest. Some asserted that the imago emerges when its wings are still soft, whilst others advance the opinion that the copula and oviposition takes place in the interior of the nest and the imago would not at all fly in the open air, and others again thought the imago to be able to get out owing to the wings being specially shaped. It has, for instance, been observed that from among those that had been bagged not one imago came out into the open air, and that, on opening the nest, it was found filled with developed imagines which were partly already in copula (ROB. MÜLLER, Mexico). The same is also the case in nature. A bag having been brought home after the flying-time of the imago, after having been opened showed quite a number of fully developed imagines lying dead on the ground of the nest, whilst a much greater multitude — judging from the number of pupae crept out — must have got into the open air.

Certainly the imago does not leave the nest, when its wings are still soft. It is only the insect being ready to fly that goes out of the bag. The oblong, peculiarly narrow shape and the somewhat proximally indented costal margin of the forewing enable the imago to appress the wings lengthwise close to the body and in this way to pass even narrow openings. Nevertheless a great number of imagines cannot get out of the comparatively narrow holes of the extremely tenacious nests. But now we must consider that, at the beginning of the flying-time of the *Eucheira* in the month of May, the rainy period sets in with heavy showers, so that the larval web is turned by the water into a most flexible and ductile state, and the imago is in this way able to leave its prison. That this theory is correct is manifested in a great number of the bags by the outlets of the nests having been enlarged from inside, which was only possible by way of dampness. From bags not having been moistened only single imagines will be able to get out, and in this case the eggs are deposited in the nest and only the small larvae pass out into the open air, as has likewise been observed. The whole structure of the wings shows that the imago is but a very incomplete and lazy flier.

Of great interest were also the experiments with imagines having been bred to test their flying-power. The insects, on having been set free in the garden, exhibited a wearisome, unsteady and tottering flight of short duration and had evidently great pains to reach by and by the height of the garden-wall near by (R. MÜLLER).

In May 1911 P. BÉNARD, on the Carboncillo Mine near Zacualpan in the State of Mexico, made the surprising discovery that *Eucheira socialis* regularly came to the electric arc-lamps of the mine at night (between 8 and 10 p. m.). We must remark thereby, that these lamps were in the immediate neighbourhood of extensive stocks of Madroño which always bear a great lot of bags of *Eucheira*. BÉNARD himself never observed lepidoptera in this district in daytime, as at any rate these specimens taken by him at night are the first flying *Eucheira* observed in nature, of which the entomologists and collectors known to me here are aware of. In my entomological practice I have often been able to observe Rhopalocera on electric arc-lamps at night, which is here in Mexico especially the case with Hesperids, but they were always only single insects having been scared up, which appears to be out of the question with the *Eucheira*. At any rate this nocturnal flight explains the remarkable absence of the insect in daytime, and we find in this most interesting diurnal lepidopteron the fact being quite unique for a Pierid, that both the larva and imago exhibit entirely the habits of a nocturnal lepidopteron, so that we must regard this insect to number among the most interesting features of the copious and multiform lepidopteral fauna of Mexico and even of the whole world. That the local (Mexican) collectors have not noticed this nocturnal flight before, may be chiefly due to the fact that the arc-lamps were too far away from the woods and food-trees as to be reached by the *Eucheira* with their limited flying-power, and that here in the Valle de Mexico, as in many other districts, the lepidoptera have disappeared in the immediate neighbourhood of the settlements, since the pupae are eagerly collected by the native Indians and eaten as a delicacy." (CARLOS HOFFMANN.)

As the figure on t. 18 a has been reproduced according to an old, faded specimen (fresh specimens were not to be obtained at that time), we produce the figure of a ♂ from a fresh specimen. In the structure of the veins of this species there occur extensive variations, in the subcostal and discocellular veins, which, however, are not confined to the single sexes, but are also found in one and the same specimen. CARLOS HOFFMANN also has ascertained an intense variability in the white marking, thus there occur ♂♂ with almost black hindwings, whereas the 5 ♂♂ and 9 ♀♀ exhibit but slight differences in this respect.

T. macrodice Stgr. (18 c, d) is declared by PEDRO JÖRGENSEN who edited a monography on the Pierids of Argentina and the neighbouring districts to be a separate species different from *microdice* Bleh. (p. 56), but owing to the lack of material the latter could not be figured. — *macrodice* also occurs in Argentina.

T. orthodice Weym. (18 e). Of this species PEDRO JÖRGENSEN also figured the ♀. It has a broad black margin of the forewing, into which the white border of the black sagittiform spots extends; the white veins of the hindwings are above and beneath rather broadly bordered with black, in a similar way as in *pyrrhomma* (18 d; the forewing beneath exhibits no other marking but the fine black scaling of the veins. It also occurs in Argentina (Salta, Caltamarca).

T. demodice Bleh. has been found again by PEDRO JÖRGENSEN in South Patagonia and Fuegia. The figured specimens (194 a) are from Patagonia (Chubut).

T. sagittata Rüb. (18 c) has been declared by PEDRO JÖRGENSEN to be a distinct species.

T. joergenseni sp. nov. (194 a) from Ecuador (Baur) is before me in a ♂. It resembles *sagittata* (18 c), *joergenseni*, but it has much fainter markings on the forewing above, and the hindwing is not marked except a fine black marginal line and insignificant black scaling of the veins; the yellow lines feebly show through from beneath. The palpi are below in *sagittata* yellow and black, whilst in *joergenseni* they are only black-haired, the antennae

in the latter being more intensely white-ringed than in the former, and in *joergenseni* the first two subcostal veins branch off at a greater distance from the end of the discocellular than in *sagittata*.

distincta. **T. distincta** Jörg. (194 a) has been discovered by the author in the Acomzuija Mountains (Argentina). The upper surface of the ♀ forewing is similar to that of *macrodice* (18 c), the upper surface of the hindwing is like that of the ♂; the forewing beneath shows a submarginal row of black hook-shaped spots.

punctata. *T. stigmadice* Stgr. (194 a) was declared to be a distinct species by PEDRO JÖRGENSEN. The figured specimens which I owe to his kindness, are from Esquina Grande; the species flies in November and March, thus in 2 generations. — *immaculata* Rüb. (18 e), according to PEDRO JÖRGENSEN, also occurs in Bolivia. — ab. **punctata** Jörg. differs from *immaculata* by the forewing being purely white and the hindwing slightly cream-coloured; the veins of the hindwing exhibit similar markings as the apex of the forewing, the yellow stripes of the under surface showing through; the black discal spot of the forewing is comma-shaped as in *orthodice* (18 e), but a little more bent, all the veins being fine black, in the apex there are triangular, black spots.

marmorata. *P. monuste* ab. **marmorata** Jörg. has yellow colouring at the apex of the forewing beneath, and beside the blackish colouring at this place of the wing also the same at the apex of the hindwing beneath. This race forms a transition to *orseis* in which, particularly in the female, there is mostly much dark marking on a yellowish or white ground.

P. itaticayae Foett. (19 d), according to P. JÖRGENSEN, has likewise been found in Argentina. According to ZIKAN's statement, it is merely a form of the extraordinarily variable *monuste* (p. 57).

gargara. *P. buniae* **gargara** Fruhst. „A relatively small race much more approximating the forms of the Lower Amazon than its Brazilian allies. It may therefore be rather inserted in *phaloe*. There are now ♀♀ before me with a much receding black border of the forewing and but insignificant grey dusting on the hindwing above, so that I presume that only the „dry season“ form is lying before me. The boomerang of the forewing is rather narrow. A ♀ is above almost white, another one almost entirely yellow. Patria: Matto Grosso. Under surface of hindwing yellow with a strongly parted discal brown band. Also here we must insert two more forms from the Coll. STAUDINGER: **artaxata** *subsp. nov.* being allied to *phaloe* and *gargara*, but still smaller, beneath still paler than the Obidos-race, and the brown discal transverse bands of the hindwing beneath remarkably narrowed. *gerosa*. It is questionable whether it is also a dry season form: Patria: Venezuela. (Type Coll. STAUDINGER). — **gerosa** *subsp. nov.* ♀ differs from that of *phaloe* from Obidos by the purely white discal region of the hindwing beneath and the more than twice as extensive and jet-black instead of brown transverse bands of the median and costal region of the hindwing. Patria: Amazon from Itaituba upwards. — **masinissa** *subsp. nov.* ♂: Above with a broader black apex than the form figured by GROSE-SMITH and the Ecuador form. ♀: beneath throughout pale straw-coloured with remarkably broad black circumcellular spots which are distally united like a band and extend up to the subbasal band. Patria: Bolivia, GARLEPP leg. Type in the Coll. STAUDINGER.“

pallida. **F. pallida** Scudd., according to WRIGHT's figure, is a form (of *napi*) entirely unmarked in the male, whilst the female is only above very little marked. Western coast of North America.

flava. **F. flava** Wr., from the western coast of North America, is a form of *sisymbrii* (19 c) being above and beneath light yellow.

nelsoni. **F. nelsoni** Wr. from the same region, according to the figure, seems to be a *beckeri* (19 c) exhibiting on the hindwing above black-hued veins and beneath submarginal dentate marking.

calyce. **F. calyce** Edw. is presumably a small, intensely marked form of *occidentalis* (19 c); from the western coast of North America.

bryonae. **F. bryonae** Wr. is a much lighter form of the palearctic *napi bryonae* (Vol. I, t. 21 c). Western coast.

castoria. **F. castoria** Reak. is a very light form of *napi* (vol. I, t. 21 b); western coast of North America.

marginalis. **F. marginalis** Scudd. is apparently a small, but little marked form of *rapae* (19 b). Western coast.

leucania. *P. pallida* Rüb. (p. 61). This name having already been disposed of in this genus, I denominate this subordinate species **leucania**.

P. pylotis Godt. (19 d) also occurs in Argentina (Corrientes) and *menacte* Bsd. (19 b) in Buenos Ayres. About *P. lactea* Burm. from Argentina I am sorry not to be able to make any statements.

diagnita. **Leptophobia diagnita** Jörg. (194 b) from Argentina (Prov. of Catamarca, 1640 m) flies in April and May and in November and December on the blossoms of *Oxalis* and other insignificant plants. It is closely allied to *elcone* (20 c); beneath less yellow than the latter, the marginal dots of the hindwing beneath scarcely noticeable, at the base no yellow spot, the anterior dot at the end of the discocellular only traceable.

Of *Perrhybris lorena* Hew. (20 f) A. H. FASSL captured a neuter on the bank of the Rio Estanzuelo (East Colombia, near the small town of Villavicencio). The female (right) half differs from typical ♀♀ by the median band being yellow in the distal half and by the subapical band being dusted with red; the red median band of the hindwing shows an admixture of yellow scales.

P. pyrrha F. (p. 64), according to BURMESTER, also occurs in Argentina (Misiones). Presumably one of the southern forms is meant by it.

Pereute swainsoni ♀ form. **albosignata** Niep. The description runs as follows: the transverse band of *albosignata*. the forewing above and beneath of a pure white, basal spots of hindwing beneath white, the costal-marginal spot, being otherwise yellow, is here also white and basally shortened. Length of forewings: 32 mm. Brazil (São Joao).

Archonias critias rubrosparsa Stich. from Ecuador (Macas) is a subspecies being almost monotonously *rubrosparsa*. black in both sexes; the hindwing above shows 3 small red discal spots and the under surface beside these 7 yellow marginal spots. — *regillus* Fruhst. (p. 67) has been withdrawn again by its author.

Charonias eurytele aurantiaca Fruhst. „Smaller than *eurytele* Hew. (21 e), the spot at the cell-apex and *aurantiaca*. the small transcellular stripes reddish instead of yellow and almost extinct. Patria: Ecuador, exact habitat not stated, but presumably from the Pacific part of the Andes.“

Appias drusilla ab. **nana** Ferr. d'Alm. is a minute ♀-form with narrowed black margins which are broken *nana*. up into spots on the hindwings; the yellowish colouring is also very much reduced. It flies in June. Rio de Janeiro. — **molpadia** Hbn. from Portorico is a ♀-form with scarcely any markings; it invariably shows a black *molpadia*. spot at the end of the forewing above and beneath, and sometimes a faint blackish hue at the distal margin of the forewing above.

Cathaemia hirlanda planasia Fruhst. „♂: forewing above white with a very broad, black subapical band *planasia*. extending along the apex of the cell. Hindwing above slightly light yellow. Forewing beneath of a pure white with a yellow cell and a darker yellow subapical spot. Hindwing light orange with a reddish-orange, complete submarginal band being on both sides only narrowly bordered with a greyish black. The black discal band without a basally emanating region as in *hirlanda*, *praeclara* etc. Patria: Matto Grosso, Cuyaba.“ — **minturna** *minturna*. Fruhst. „♂♀ with broader black subapical bands of the forewing than specimens from the Amazon, Colombia and Peru. Hindwing beneath yellow with very pale submarginal bands posteriorly dying away, but which in the ♀ turn orange. Patria: Venezuela.“ — **posidonia** Fruhst. „The darkest specimen of the Coll. STAUDINGER *posidonia*. is from Colombia and differs from *hirlanda* and its forms by the much broader black distal margin on all the wings and an especially broad reddish-yellow, complete submarginal band of the hindwing beneath proximally broadly margined with black. The median and postdiscal areas of a magnificent yellow. Patria: Colombia, Putomajo.“

Leodonta batzebina subsp. nov. has on the forewing above light yellow, on the hindwing dark yellow *batzebina*. colouring; the marking is about the same as in *dysoni* (21 e), but the submarginal spots are smaller; also the hindwing beneath has much yellow marking. Colombia (Muzo).

Catasticta rubricata Weym., described from West Colombia (Cauca Valley), seems to be the same *rubricata*. species as *Archonias pharnakia* (21 e), since it merely differs by a slight increase of the marking especially on the hindwing beneath. It is a matter of opinion to place this species to *Catasticta* or *Archonias*; in its exterior *pharnakia* agrees better with *Archonias* than with *Catasticta*. The name *rubricata* seems to have the priority.

Cat. hegemon G. & S. The description says: „Similar to *sisamnus*, but the band of the forewing *hegemon*. is broader and the margin of the hindwing much more extensive. ♀ similar to the ♂, scarcely coloured yellow. We have specimens of both sexes and it can scarcely be doubtful that the species differs from *sisamnus*. Not only the discal spots of both wings are larger, but those in the hindwing also flow together with the transverse band. Thereby the distal margin is much narrower and its proximal border very irregular, almost serrate. ♀ quite similar to the ♂, but as much as our specimens exhibit, the cellular band is white and not yellow as in most of the ♀♀ of the other species. Patria: Costa Rica, Panama, Veragua, Chiriqui, Colombia, Ecuador.“ *hegemon* is not known to me from autopsy, but it seems to me that **albescens** nov. (194 b) from West *albescens*. Colombia (Rio Agua, 2000 m, A. H. FASSL) represents a local form of this species; the discal spots of the forewing are smaller, and there are not 3, but 2, the dark border of the hindwing being more reduced; I cannot tell in what way the under surface differs. — It is doubtful whether **helle** nov. (194 b) from West Colombia *helle*. (Cauca Valley) belongs to this species or is a different species. — **chiricana** nov. (194 b) well agrees with *helle* *chiricana*. beneath, but it is larger and above rather different. Volcano of Chiriqui.

Cat. argolis sp. nov. (194 b), as the figures show, differs rather much from *pitana* (22 c). Before *argolis*. me are 3 ♂♂ and only 1 ♀ which exhibits a but very faintly yellowish discal band and a somewhat more abundant white marking. Peru (Pancartambo, S. Rosa) and „Colombia“.

cerberus.

Cat. cerberus *G. & S.* from Costa Rica which has remained unknown to me, has been described as follows: „♀ wings sooty, the usual white band (on the forewing broken up into spots) proceeds from the costal margin of the forewing behind the discal cell and extends to the proximal margin of the hindwing, almost disappearing fine (white) spots at the discal cell of the forewing, the usual row of submarginal and on the hindwing also marginal white spots; forewing beneath almost as above, the submarginal spots larger, with 5 yellow marginal lines, the discal bands of the hindwings running across the discal cell, parted by the veins, the other submarginal band distally deeply serrate, also parted by the veins, at the margin itself triangular and at the base of the wing white spots, between the veins small lines, that in the discal cell prolonged, the latter saffron-coloured like the marginal spots. ♂ hitherto unknown. We have but 1 ♀ of this species, differing from all the others known to us. It may be the most closely allied to *tomyris* *Fldr.* (22 f), but a comparison of the figures clearly exhibits the differences.“

Cat. pinava (22 b), according to LATHY & ROSENBERG, is said to be *boliviana* *Btlr.*

Cat. vapina (p. 70), according to LATHY & ROSENBERG, is said to be synonymous with *incerta* *Dogn.*

Cat. philomene (p. 71) which we figure on t. 194 c, is by no means identical with *colla* (22 b), as LATHY & ROSENBERG pretend.

Cat. hopfferi (22 c), according to LATHY & ROSENBERG, is said to be identical with *pinava* *Dbl.*, but they do not state what they think the insect to be figured on t. 22 b as *pinava*; also in this case, if the said authors are correct, the description is insufficient; the description, however, does by no means agree in every respect with *hopfferi*, for which reason the denomination of this species as *hopfferi* will have to be adhered to.

Cat. modesta (22 e) is said not to agree with the type and the latter to resemble *pinava* *Dbl.*; LATHY & ROSENBERG would have set a meritorious example by figuring the species which have been insufficiently described or not figured, since these species cannot be cleared up without any figures of the types. — The species figured on t. 22 e as *modesta* is said to be *strigosa* *Btlr.* (p. 72), but the description of the under surface does in no way fit the species figured by us as *modesta*. BUTLER compares it with *ctemene* (22 c), the correct determination of which has not been contested by LATHY & ROSENBERG.

Cat. affinis (22 d), according to LATHY & ROSENBERG, is said to be identical with *philone* *Fldr.*; the latter is said to occur in Venezuela and Ecuador, whereas *affinis* has been established from Colombian specimens; presumably there are nevertheless differences between both; a comparison with the type is not possible, since the latter is in England.

albina. **Cat. albina** *L. & R.* (= *zebra* *Fruhst.*) (194 b) is presumably a conspicuous local form of *hebra* (22 d);
zebrella. the under surface is lighter, and the light stripes of the forewing are more yellow. Bolivia. — **zebrella** *Fruhst.* is smaller and darker without any white apical stripes of the forewings. Peru.

scurra. **Cat. scurra** *Stgr. i. l.* (194 c) differs above and beneath to such an extent from *manco* (194 c) that it must be considered as a separate species. From the Upper Amazon (Peru).

bithyna. **Cat. bithyna** *Stgr. i. l.?* (194 c) differs above very much from all the other species, as the figure shows, whilst the under surface is very much like that of *pitana*. Colombia.

philonarche. **Cat. philonarche** *Fldr.* (194 c). We figure the two species lying before us, which presumably belong to this species. The descriptions by the authors FELDER are mostly of such a kind that the species described cannot be ascertained from them. The specimens figured vary a little from each other above and beneath, though not to such an extent that they would have to be considered as the representatives of different species. Habitat: Colombia (Cauca Valley?).

philais. **Cat. philais** *Fldr.*, **philone** *Fldr.*, and **potamea** *Fldr.* What we have said of the *philonarche*, also
philone. refers to the original descriptions of these species. There are no specimens before us that might correspond
potamea. with these species, not even in a questionable way. Patria: of *philais* and *philone*: Colombia; of *potamea*: Venezuela.

pieridoides. **Cat. pieridoides** *Fldr.* is presumably the somewhat darkened form of *pieris* (22 a), the patria of which is Colombia (as stated Bogotá).

hübneri. **Cat. hübneri** *L. & R.* (194 c) from Southern Brazil (Leopoldina and São Paulo) is a smaller form with narrowed white markings of *bithys* (22 d). The habitat stated by the authors, „Peru“, is presumably incorrect.

flavomaculata. **Cat. flavomaculata** *L. & R.* is the southern form (from Costa Rica) of *tentila* (22 g), differing beneath
zeneda. by orange instead of yellow markings. We cannot ascertain whether the following form differs sufficiently from it. — **zeneda** *Fruhst.* „♂ considerably smaller than *teutila* *Dbl.* (22 g) from Mexico, with a much narrower whitish median band above on both wings. The ♀, however, has a broader orange median zone. Habitat: Costa Rica.“

troezene. **Cat. troezeze** *Fldr.* according to the author's figure, is a species with a yellow upper surface, somewhat like *marcapita* (22 g), smaller, with small, yellow apical spots of the forewings, a distinct yellow patch in the cell of the forewing, hindwing with a black margin as in *paradoxa* (22 g), distinct yellow marginal spots and

black submarginal spots coherent with the black margin in the anterior part; under surface somewhat lighter, hindwing with black cucullate spots at the distal margin on a yellow ground and a black dentate median band. Colombia. LATHY & ROSENBERG denote FELDER's figure to be extraordinarily marred, and put stress upon the great resemblance of this species with *troezenides* (22 d) and positively assert both the subspecies to be one and the same species.

Cat. zande Fldr. (p. 73 as synonym to *cora*) has, according to the material of the British and Paris Museums, been recognized by LATHY & ROSENBERG (Trans. Ent. Soc. Lond. 1911, p. 521) to be synonymous with *cora* Luc. and *paradoxa* (22 d) likewise synonymous with this species. The said authors state that *cora* has hitherto not been correctly identified by anybody, what is due to the insufficient description. But as our figure of *paradoxa* corresponds with the description of *cora* Luc., it has to be regarded as the typical one, and the name *cora* has to be cancelled and replaced by the name *paradoxa* the description of which is accompanied by a correct figure.

Cat. manco Dbl. has likewise been mistaken hitherto. LATHY & ROSENBERG have described and figured the ♀ at the place cited above; we reproduce the figure (194 c). South Peru, 7000 ft. (LATHY & ROSENBERG); Bolivia, 3000 m (A. H. FASSL). The species figured by us on t. 22 a as *manco* is, according to the aforesaid authors, *incerta* Dogn. The work in which this species is figured (Lep. Loja II) is not accessible to us.

Cat. ochracea Bat., according to LATHY & ROSENBERG, is the Guatemala-form of *nimbice* (22 b); we could not obtain any specimens of it; it is presumably little different.

Cat. amastris Hew. is said to be the ♀ of *niobe* (22 d); *amastris* is unknown to us.

Cat. apaturina (22 f). LATHY & ROSENBERG remark that the specimen figured by us does not correspond with the type (in the British Museum), because the latter exhibits a white band of the hindwing, and that it apparently corresponds more with *truncata* having been described by the said authors. Our specimen originates from Ecuador, the habitat of the *apaturina* Btlr., *truncata*, however, from Venezuela. In our specimen the band of the hindwing is still darker yellow than in our figure, but still lighter than in the figure of *truncata*; the under surface of our specimen differs considerably from that of *truncata*: whilst the forewing does not show great differences beside its darker ground-colouring, the hindwing exhibits both in the distal and basal areas a light bluish shine and at the costal margin a white stripe which is only in the middle narrowly interrupted by black, and at the end of the discal cell there are 2 yellow dots. In case this specimen should belong to a separate species, it may be denominated: **xanthotaenia**.

Cat. tolima Fassl. „Allied to *C. incerta*, but the ♂ much more golden yellow with lighter marginal triangles on both wings; beneath still lighter, especially in the hindwing. The insect makes the impression of a *C. manco* (194 c) having turned entirely orange, but all the dark parts, also the base of the wing, the cell and the black-tinted veins are much less dusted dark. The ♀ presumably belonging to it is very much like that of *manco*, but all the marginal wedge-shaped spots are more pointed and those of the forewing more distinct, and the whole ground-colour is of a purer white, too.“ Monte Tolima in the Colombian Central Cordilleras at an altitude of 3200 m.

Cat. soccorensis Fassl. „Size, colouring and marking above very much like that of *C. semiramis* (22 d); but the yellowish-white oblique band passing through the middle of the hindwing is almost entirely absent. The costal margin of the forewing is still more indented; the hindwings are more sharply dentate. Quite different is the under surface which recalls the most that of *C. niobe* (22 d) but is still more distinctly marked. The yellow radiary rays thereby become much more distinct, so that they are, just like the median oblique band of the hindwing, situate on a bluish-grey ground (not light yellow as in *niobe*). The dense hairing of the head, thorax, and bases of the wings is of a lustrous black and much darker than in *niobe*. This new, charming *Catasticta* is a decidedly alpine insect of which I only captured a single specimen on the summit of Mount Socorro in the Colombian Western Cordilleras, at an altitude of almost 4000 m, where it was drinking in the company of the red *C. tricolor* in a snug, picturesque gorge at the bank of an icy brook. It probably represents the *C. niobe* of Peru and Bolivia in Colombia.“

Cat. modesta Luc. (22 e) ♀ ab. **rubricata** Fassl. „A form with a rosy instead of sulphur-yellow spot of the forewing, which also shows through beneath though somewhat paler. The insect looks above very much like *Archonias pharnakia* Fruhst. (21 c), but beneath it has the typical marking of *Cat. modesta*.“ Colombian Western Cordilleras, at an altitude of 2300 m.

Cat. apollinari Fassl ♂ „is a form of *modesta*, in which all the markings above are whitish-grey, not olive-yellow as in the type. It forms the transition between *modesta* and *troezen* (p. 105) and probably replaces these forms on the eastern slope of the Colombian Eastern Cordilleras; whilst farther to the south in Peru and Bolivia the *modesta*-forms are replaced by the still whiter, thus certainly closely allied *C. hebra* (22 d).“ Rio Negro, Colombia, Eastern Cordilleras, 800 m.

Cat. lubentina Fassl „approximates the red *tricolor* (p. 73), in the company of which I also captured it on the Quindiu Pass in the Colombian Central Cordilleras, at an altitude of 3800 m. The forewing shows

purely white markings in the shape of a large discal spot parted by the veins and an irregular submarginal band being in the ♂ but indistinct and consisting of dots and longitudinal streaks. The hindwing shows the very same fiery red marking as *C. uricoecheae* (22 f), but the marginal triangles are particularly in the ♀ much broader and distally bordered with snow-white. The under surface is very much like that of *C. uricoecheae*; the white spot of the forewing shows through beneath; the yellow radiary streaks are more incisive and somewhat longer. The insect flies in the forenoon in the sunshine on blossoming shrubs, especially on the extreme tops, where it is difficult to capture. I often waited for days in these high and cold regions eternally hidden in fogs for a glimpse of sunshine; sometimes the morning was so cold that even at noon all was still covered with frost in the shade, and I often had but quite short sunny moments during the day, immediately followed by rain intermixed with sleet and snow." (FÄSSL).

- dentata*. **Cat. dentata** L. & R. (194 d) from Southern Peru (Acopampa), at an altitude of 11500 ft., in February and March. According to the authors' opinions it is the Peruvian form of *amastris* (= *niobe*, 22 d).
- albofasciata*. **Cat. albofasciata** L. & R. from Colombia (Maganja), 9000 ft., February. It entirely resembles above our figure (22 f) signed with „*uricoecheae*“, but the dull grey-dusted spots in the discal area of the forewing are here almost purely white.
- seitzi*. **Cat. seitzi** L. & R. (194 d) from West Colombia (Guabinas on the Rio Cauca), January.
- watkinsi*. **Cat. watkinsi** L. & R. from Southern Peru (Uruhuasi), 7000 ft., March, April. Almost exactly like *seitzi*, but the basal part of the hindwing, especially in the cell darkened with brown.
- distincta*. **Cat. distincta** L. & R., Peru (Rio Colorado) 2500 ft. (La Merced), North East Peru (Huancabamba), August. Larger than the preceding, but otherwise above similar to them, the basal half of the wing darker, the submarginal spots of the hindwing larger. Beneath the marking is more uniform, the ground lighter, the brown postmedian band broader and more distinctly defined.
- leucophaea*. **Cat. leucophaea** L. & R. (194 d). Peru (Uruhuasi, 7000 feet), North East Peru (Huancabamba), 3 to 10 000 ft., March.
- lanceolata*. **Cat. lanceolata** L. & R. (194 e). West Colombia (Torne in the Cauca Valley), August.
- minor*. **Cat. minor** L. & R. Peru (San Ramon, 3000 ft., Rio Colorado, 2500 ft.), March, April. Very much like *watkinsi* and *distincta*, from the latter slightly different by the ground-colour above being more uniformly greyish-brown, the base of the forewing not being so very sooty blackish; beneath the base of the forewing is yellow, without the extensive blackish-brown dusting of *distincta*, and the brown postmedian band is narrower.
- subflava*. **Cat. subflava** L. & R. (194 e). North East Peru (Huancabamba) 3 to 10 000 ft.
- punctata*. **Cat. punctata** L. & R. Southern Peru (Uruhuasi, 7000 ft., Cuzco), March, April. Above almost exactly like *subflava* (194 e), but beneath the distal part of the wing is browner, especially the dark postmedian band broader and less interrupted.
- aureomaculata*. **Cat. aureomaculata** L. & R. Southern Peru, 7000 ft., March, April. Above somewhat like *suasa* (22 e), but the light parts more ochreous than sooty brown; beneath similar to *phile* (194 f), but the yellow spot in the cell-end of the forewing much larger, the small spots of the median band in the hindwing smaller, but whiter, the light, small marginal spots of the hindwing more distinct.
- suffusa*. **Cat. suffusa** L. & R. (194 f). North East Peru (Huancabamba), 3 to 10 000 ft.
- superba*. **Cat. superba** L. & R. (194 f). Southern Peru (Uruhuasi), 7000 ft., February till May.
- similis*. **Cat. similis** L. & R. Southern Peru, 7000 ft., April, May. Above similar to *subflava* (194 e), but the hindwing beneath of a bright and pure yellow, reticulated with blackish-brown like in *manco* (194 c).
- intermedia*. **Cat. intermedia** L. & R. „♂ very similar to *innuba* Rōb. (p. 70), but larger and lighter, the marking on the hindwing beneath much yellower. Southern Peru (Uruhuasi), 7000 ft., March till May.“ An intermediate form of *innuba* and *pieris* (22 a).
- suprema*. **Cat. suprema** Fässl. ♀. „The largest of the red *Catasticta*-forms and probably allied to *C. vulnerata* (p. 73) being unknown to me. All the median bands, also those of the forewings, brownish-red and only near the costal margin of the forewing turning somewhat orange. The submarginal dots of both wings and the small marginal spots of the hindwing sulphur-coloured; fringes narrow and white. Beneath similar to *uricoecheae*, but the red of the forewing, especially in the lower part, showing through; the yellow radiary streaks of the hindwing beneath very narrow, almost hardly traceable. Body densely haired black. A single ♂ from the Quindiu Pass, Colombian Central Cordilleras, 3800 m, where it was drinking from the blossom of a lilac-like shrub.“
- susiana*. Of **Cat. susiana** Hpff. (= *collina* Stgr. i. l., *calanga* Stgr. i. l.) (194 e) we reproduce the figure of the under surface. (Peru).

Cat. philothina *Stgr. i. l.* (194 c) is above much darker than *manco* (194 c) and beneath quite differently *philothina*, marked and coloured. Ecuador. — **incertina** *subsp. nov.* (194 d) from Colombia resembles *philothina* (194 c) *incertina*, above, but it is marked more grey, whereas the under surface is very different.

Cat. phile *Stgr. i. l.* (194 f) seems to be allied to *pinava hopfferi* (22 c), but the upper surface is less *phile*, marked yellow and the under surface very different. Peru (Chanchamayo).

Cat. zanclicides *Stgr.* has formerly been in the market by the name of *philonarche*. As the figures exhibit, *zanclicides*, it differs considerably from the latter. Colombia (Cauca and Aguaca Valleys).

Cat. zanclicoides *Stgr.* (194 f) differs from *zanclicides* more above than beneath; the under surface is *zanclicoides*, not so distinctly and less marked white, and on the discal band of the hindwing it shows less violet colouring. Peru. Similar to *watkinsi*.

Cat. subtoca *sp. nov.* (194 f) is before us in a female specimen. It is above entirely different from *subtoca*, *toca* (22 f), but beneath similar, though it is without the conspicuous yellow spot at the end of the discal cell of the hindwing. Venezuela (Merida). It also resembles *seitzi* (194 d).

Cat. scurra *Stgr. i. l.* (194 c) from Peru resembles *leucophaea* (194 d), but it is much darker, also in *scurra*, the marking, especially beneath, it is very different.

Cat. chelidonides *sp. nov.* (194 g). Of this species 1 ♂ from Peru (Chanchamayo) and 1 ♀ from Venezuela *chelidonides*, (Merida) is before us. We have figured the upper surface of the ♀ and the under surface of the ♂. In the ♂ the light markings above are more intensely yellow, also the marginal and submarginal spots more distinct; in the ♀ the markings beneath are more blurred and the colouring is paler than in the ♂.

Cat. variabilis *sp. nov.* (194 g) varies considerably in the extent of the greyish yellow colouring above, *variabilis*, and also beneath the markings, particularly the yellow marginal spots, differ in size. Colombia.

Cat. latiplaga *sp. nov.* (194 g). Two ♂♂ of it are before us; the specimen figured from beneath has a *latiplaga*, much narrower and very light yellow basal area of the hindwing; this difference is also present beneath. Colombia (Pacho, Eastern Cordilleras — the yellow specimen; the other specimen from Colombia without the exact habitat being mentioned).

Cat. pallens *sp. nov.* (194 g) resembles *zanclicoides* (194 f) above, but the yellow discal spots of the *pallens*, forewings are shorter, arranged in the shape of a uniform band, the submarginal spots are smaller and in the posterior two areas absent, the hindwing also with a uniformly broad discal band, the marginal and submarginal spots only traceable. Beneath different from all the species known by the pale colouring. Peru.

Presumably some of the species above mentioned as new species are identical with such that have been described in an irre recognizable way by older authors. As we have now figured them, it will no more be difficult to recognize them from the „types“ that may yet be extant.

Daptonoura daguana *Fassl* ♂. „A large *florinda*-form (23 b) with an expanse of 64 mm and a broader *daguana*, black border of all the wings; the hindwing towards the anal margin passing from the bright orange colouring over into an intense chrome-colour. Beneath with a much broader black cell-end spot of the sulphur-coloured forewings. Hindwing beneath intensely chrome-coloured (not sulphur-coloured as in the typical form). In the 2 mm broad black distal margin two, likewise deep yellow, long streak-shaped spots.“ San José (180 m above the sea-level) on the Rio Dagua in West Colombia, thus very close at the shore of the Pacific Ocean.

Dapt. caesarea *Fruhst.* „A distinguished species, allied to *florinda* *Btlr.* from Central America and *caesarea*, to *inaequalis* *Btlr.* from Peru, above magnificently light yellow with a very narrow black cell-end. Under surface of forewing sulphur-coloured, of hindwing orange. Cell-end broadly encircled with black, distal margin relatively narrow and as in *polyhymnia* *Fldr.* covered with small, yellowish maculae. West Colombia (Rio Magdalena). — Scarcely different from *polyhymnia* (23 b).

Dapt. vecticlusa *Btlr.* = *Appias drusilla* *Cr.* (21 f) — according to KIRBY, Catal. Diurn. Lepid. *vecticlusa*.

Dapt. flippantha *F.* is according to KIRBY's Catal. Diurn. Lepid. = *limnoria* *Godt.* (p. 75). *flippantha*.

Dapt. lycimnia narmia *Fruhst.* „Upper surface purely white, by the apical spotting allied to *maeotis* *narmia*, *Fruhst.* from Peru. The under surface, however, is absolutely identical with *pantoporia* *Hbn.* from Espiritu Santo and Minas Geraes. Another form, by the distal margin of the hindwing being covered with small white dots, somewhat resembles *phazania* *Fruhst.* from Bahia and forma *daulia* *Fruhst.* from Colombia, only the margin is like in *pantoporia* very narrow, but covered with white not with yellow as in *pantoporia* (forma *othoca* *othoca*, *nov.*).“ Patria? — **semiobscurata** *Weym.* from Ecuador (Macas) has very broad black marking above and beneath; *semiobscurata*, the larger distal half of the hindwing beneath is dark brown, the proximal bordering of this marking very irregular and faded. — *lycimnia* is said also to occur in Argentina (Misiones).

Dapt. florinda ab. **discocellularis** *Strand.* The original description runs as follows: „A ♂ without the *discocellularis*, patria being stated, distinguished by the forewing, according to the figure in Biologia Centrali-Americana, exhibiting also above a black discocellular band, which, according to the original description, is in the typical

form the case only in the ♀ (RÖBER in SEITZ mentions this band of the forewing above neither in the ♀).“ — We remark hereto that it was not necessary to state this difference from the ♂ in this species specially, because it is a general character of the ♀♀ of this genus; to my knowledge only *regnidas* (23 c) does not exhibit a discocellular band, but this is presumably an aberrative form, whereas the normal ♀♀ probably have such a band.

palaestra. **Dapt. palaestra** *Hpff.* (p. 76) has of late been regarded as a distinct species, for which reason we have
equadorica. figured it (194 g). — **equadorica** *Strand* from Ecuador (Sarayacu) has been described as follows: „Distinguished from the two types (♂♂) of the species lying before me by its larger size (expanse of wings: 57, length of forewings: 34, length of body: 22 mm), a broader marginal band (at the apex of the forewing 11 mm, along the vein 3 in the forewing 4 mm, in the hindwing 4½ mm broad) which is besides not proximally bordered undulately in the hindwing; besides by the whitish under surface and the narrower (in f. pr. triangular) discocellular spot.

loranthi. **Mathania loranthi** *Jörg.* (194 g) is much smaller than *leucothea* (23 b) and easily discernible by the much more taperingly extended hindwings. The indistinct marking beneath is entirely like that of *leucothea*. Common in the valleys of the Andalgalá at altitudes of 150 to 250 m, in February and May. Larva on *Loranthus eugenioides* Kth., of the usual Pierid shape; pupa remarkably bent.

carrizoi. **M. carrizoi** *Giac.* „Most closely allied to *M. leucothea*, but quite different; wings uni-coloured white with a faint greenish hue, less than in *leucothea*; more yellowish; this comparatively more on the upper surface of the wings. Forewing of *carrizoi* with a slightly yellowish or greenish apex which in *leucothea* is of a deep and very pure light green colour, and on the ground there is a row of small greenish clouds, forming a semicircle round the margins of the wings, concentric to them. This varies greatly in my 4 specimens, so that in one it is hardly visible, whilst in the others it is more distinctly marked; a yellow, faint, little visible dot is the dot, in the space of the two veins forming the disc of the hindwing; body haired, in one specimen at the base of the eyes a small dot as in *leucothea*. Antennae similar as in *leucothea*. Size variable, expanse: 44 to 58 mm. Catamarca (Sa. Cruz and El Saladillo, La Rioja, Tucuman) and Bolivia.“

melissa. **Hesperocharis melissa** *Ferr. de Alm.* Size approximately that of *erota* (23 e). The description says: forewing white or greyish-white, apex slightly fox-coloured. Hindwing light greyish-white. Forewing beneath above, hindwing beneath yellowish-white, often at the base with an orange spot. Thorax black with light stripes. Abdomen light yellowish. Antennae blackish, at the apex yellowish. It flies in July. Patria: Rio de Janeiro.

quichua. **H. marchali** ab. **quichua** *Jörg.* is a form more intensely marked above and beneath. Catamarca, 1640 m, in December.

lactea. **H. lactea** *Burm.* from Argentina seems to be extremely rare, since it has no more been discovered of late. The original description says: „This species has the size and shape of *anguitia*, but the forewing is a little obtuser. Body black and covered with long white hair; antennae black with a yellowish-red club, palpi and frons with black hair intermixed with white hairs; wings milky-white, the costal margin slightly yellowish towards the apex, beneath the forewing has a somewhat yellow costal and distal margin, of the same colour is the hindwing beneath, with a saffron-coloured dot at the base.“

meridionalis. **Teriocolias atinas meridionalis** *Jörg.* from Argentina (Aconquija Mountains), at altitudes of 1500 to 2700 m, is smaller than *atinas* (26 d) and above and beneath of a paler yellow ground-colour, and — especially
shiptoni. beneath — much less marking. — ab. **shiptoni** *Jörg.* shows brownish ground-colouring on the hindwing beneath, with a very indistinct marking. The imagines fly in November and at the end of May on the blossoms of Compositae, Loranthaceae, Acanthaceae, Verbenaceae and Labiatae. The larva lives on *Cassia hookeriana* Gill. The pupa is bent back, and the part of the wing-cases is bulging very much.

flavia. About **Terias flavia** *Burm.* occurring in Argentina (Tucuman) I cannot tell anything, as I neither possess specimens of it nor have access to the description.

T. arbela *Hbn.* (24 b) also occurs in Argentina.

formosanus. **T. thymetus formosanus** *Jörg.* from Argentina (Formosa), flying in November, has a somewhat broader black margin of the forewing and a diffuse, narrow, black border of the hindwing.

T. agave *Cr.* (24 f) also occurs in Argentina.

peruvicola. **Catopsilia rurina peruvicola** *Strand* from South East Peru has been described from a ♂ being very much marked beneath.

occidentalis. **Colias occidentalis** *Scdl.* from the western coast of North America resembles *chrysomelas* (27 a), but it has rounder wings and is lighter yellow, the black marginal marking narrower, the ♀ has only blurred, narrow, black marginal markings, no submarginal spots and a more or less distinct discal spot.

astraea. **Col. astraea** *Edw.* from the North American western coast is in the ♂ similar to *ariadne* (27 f), but a little larger, with more pointed wings and less orange-coloured. The hindwing has no discal spot. The ♀ is

very pale yellowish-white, without any markings except a distinct discal spot and some blackish dusting on the distal margin of the forewing.

Col. euxanthe nigerrima *Fassl* is the dark (sooty) form occurring in both sexes, but transitions to *nigerrima*. the normal form are more frequent. La Paz Bolivia, 3600 to 4000 m; Cuzco, Peru, 4000 to 4200 m. Very rare among the typical forms.

Col. tolima *Fassl*. „Similar to *dimera* (27 h) from the Eastern Cordilleras; forewing more rounded off. *tolima*. the black marginal band proximally rectilinearly defined and not extending to the proximal margin, but ending rectangularly in the middle between M² and SM². In the ♀ the black distal-marginal band differs quite analogously from the ♀ of *dimera*. The dark hue on the bases of the wings and on the border of the hindwing is much fainter than in *dimera*. One of the few diurnal lepidoptera which I discovered in exploring Mount Tolima, near the snow-limit at altitudes of 4200 to 4600 m. The insects were flying at a terrific speed along the lava-moraines. I mostly waited for a moment when the sun was hidden by nebulous clouds swiftly passing by and the insects at once dropped into the grass as if they were paralyzed, and were easily taken with the pincers.“

Col. weberbaueri *Strand*. The original description says: „♀ closely allied with *C. dinora* *Ky.* (cf. *weberbaueri*. Seitz, Macrolep. t. 27 g), but the forewing appears to be less tapering and its border more distinctly convex in its whole length (in *dinora* it is in the middle straight), the hindwing is more elongate with a still more convex resp. in the middle very bulgingly projecting border (the hindwing in this case being also slightly shorter [by 2½ mm] than the forewing). The discocellular spot of the forewing is larger and more rounded off. The dark marginal band extends to the anal angle, being in front about 7 mm broad, the proximal margin being proximally quite blurred by dark dusting, in the posterior half, however, proximally more distinctly defined, and only the veins there being dusted with black, along the vein 4 being 4 mm broad, along vein 2 about 2½ mm; the band encloses seven yellow spots, of which the four situate between the costal margin and vein 4 are a little larger and only parted by the veins, whilst that in area 3 is the smallest, and that in the anal angle indistinctly defined and sometimes not at all recognizable as an isolated spot. The ground-colour of both wings above is like in *C. dimera* ♀ (cf. op. cit. t. 27 h). Hindwing at the apex (in the areas 6 and 7) with a dark, about 2 mm broad marginal spot which, however, is almost removed by a lighter, enclosed spot. Besides there is an indistinctly lighter, scarcely recognizable marginal band of 3½ mm width. The fringes on the forewing are rosy-reddish in the anterior half, yellow like the surface of the wing in the posterior half, whilst on the hindwing they are uni-coloured rosy-reddish. Forewing beneath in the ground as above, in the costal area dusted darker, in the marginal area the markings from above show through; in the areas 5 and 7 there is at 3 resp. 4½ mm distance from the margin one small brown spot each, and the discocellular spot appears as a small, black transverse ellipse. Hindwing beneath dusted with a dark greenish-yellow, being the lightest in the marginal area, with markings as in *dinora*, the seven sublimbal spots, however, are darker and smaller, the discocellular spot is likewise darker and distally pointed in the shape of a wedge and enclosing a snow-white, oblong punctiform spot. Expanse of wings: 33, length of forewings: 19 mm. The ♂ slightly differs from the ♀, and is somewhat smaller: length of forewings 18, expanse of wings 31 mm, the ground-colour above being of a brighter yellow, the marginal band of the forewing deeper black, more distinctly marked, extending uninterruptedly and in the same distinctness to the anal angle, and enclosing before the middle three yellow spots which are quite distinct but still smaller than in the ♀, whereas the posterior half of the band shows only traces of three yellow spots. Both wings in the basal area, the hindwing besides in the dorsal area densely dusted with a pure black; the hindwing shows the same, though more distinctly marked marginal marking as the ♀. The under surface is likewise more profusely coloured yellow than in the ♀ and with more distinct markings, except the discal spot of the forewing, which is entirely absent.“

Col. strandi *sp. nov.* (192 d only the first figure) of which 1 ♂ is before me from Lake Titicaca, seems to differ from *weberbaueri*. The under surface on the hindwing and on the apex of the forewing is much distincter than in *euxanthe*-♂, thus considerably different from *dimera*-♂, the colouring of the other part of the forewing beneath, however, not yellowish as in *euxanthe*-♂ but dingy white with grey scaling, especially on the veins; the red-brown spots on the forewing and hindwing are much smaller, and on the forewing there are but 2 of them, one at the costal margin and the other subapically, in the three following areas of the wing there is one minute spot each scarcely recognizable with the naked eye. It was denominated in honour of Prof. Dr. EMBRIK STRAND.

Col. dimera ♀-f. **semperi** *Reak.* is the white ♀ form which, however, seems to be more common *semperi*. than the ♂-like ♀♀.

Col. blameyi *Jörg.* (194 d, second figure, as *strandii*) occurs in the Argentine Mountains (Aconquya) *blameyi*. at altitudes of 3200 to 3750 m and flies at the end of April on the blossoms of various Compositae, Verbenaceae and Malvaceae together with *Phulia aconquijae* and species of *Tatochila*. The under surface of the imago shows the same scheme of markings as in *euxanthe* (27 h), but in the ground-colouring it is much paler (yellowish-grey), and the discal brownish spots of the hindwing form a complete row; also the forewing shows 4 such spots.

Col. emilia *Edw.* is probably the Pacific form of *eriphyle* (27 e), somewhat smaller and paler and with *emilia*. narrower black distal margins.

Meganostoma bernardino Edw. (p. 94), according to WRIGHT's figure, is a form of *eurydice* (26 f) with *amorphae*. black distal margins of the hindwings. The ♀ does not differ from that of *eurydice*. — *amorphae* Wr. is a form of *eurydice*-♀ marked blackish.

citrina. *M. helena* ab. *citrina* Jörg. does not exhibit the orange colouring of the hindwing, but it is lemon-coloured; it is common in the Province of Tucuman from May till August.

coliaides. *Nathalis plauta* ♀ ab. *coliaides* Fassl is the ♂-like ♀ form; not rarely there occur transitions to the usual form. Bogotá, Colombian Eastern Cordilleras, 2600 to 3200 m. The insects are fond of drinking on a common, yellow blossom of *Hieracium* especially in sunny districts.

deserti. *Anthocharis deserti* Wr. from the western coast of North America is a small form of *cethura* (28 b) with scanty markings and colours.

flora. *A. flora* Wr. from the same region is a robust and more profusely marked form of *reakirtii* (28 a); *mollis*. the ♀ is above and beneath pale yellow; in *mollis* Wr. the subapical marking of the forewing above is reduced. *caliente*. Western coast of North America. — *caliente* Wr. which the author takes to be a separate species is presumably only a small and pale form of *pima* (28 a). Western coast of North America.

Of *Phulia nymphula* Btlr. (28 c) GIACOMELLI has discovered a new form in Argentina (in the Andes *reedi*. of Mendoza) and denominated it *reedi*. At present I do not know any further particulars.

aconquijae. *Ph. aconquijae* Jörg. (192 d) is common beginning from the middle of March in the Aconquija Mountains at altitudes of 3500 to 3750 m and flies together with *Colias blameyi* and species of *Tatochila*. It is above and beneath very much like *nymphula* (28 e), but the under surface is of a darker ground-colour and with a more intense and profuse marking. As there is no comparative material of *nymphula* from Chile available, it is still uncertain in what way the latter differs from the form figured on t. 28 c, which was considered by O. STAUDINGER to be identical with the Chilean form and from *aconquijae*; *aconquijae* may be synonymous with *nymphula*, in which case the Bolivian form would have to be newly denominated; it may then be called *joergenseni* in honour of the author of „Las Mariposas Argentinas“ (Buenos Ayres 1916), who has made himself very meritorious by the exploration of the Argentine Pierids.

limbalis. *Pseudopieris limbalis* sp. nov. (192 d) was discovered by Mr. A. H. FASSL, who had the kindness to send us the figured specimen; in January near Altamira on the Rio Hingu. The under surface is uni-coloured white except the yellow basal spot. If *penia* (28 e) would have to be considered as a separate species, this would also have to be done with *limbalis*.

citrinella. Of *Dism. citrinella* Fldr. (192 d) we are now able to reproduce figures of the ♂; the ♀ is still unknown to us. According to FELDER, this species occurs in Venezuela (Prov. of Merida) and in the Cordilleras of Bogotá (Colombia); before me are specimens from Western Colombia (Rio Magdalena) and Bolivia. *D. citrinella* is presumably a species scarcely different from *melite* (28 h).

core. *D. core* Fldr. is still unknown to me. The description says: „Wings above blackish, the inner-marginal band anteriorly broader with a discal, shortened oblique band of 4 yellow submarginal spots; hindwing yellow, the whole distal margin proximally above sinuate (or curved), blackish; beneath the marginal spots between the veins are of a deeper yellow, in a brown margin; the hindwing on the whole intensely brown, the basal part of the costa, 2 larger basal spots, and a broad, irregular discal band, traversed by the veins, mother-of-pearl white, in some places with an intense yellow tint, a circular subcostal macula, another one proximally and other thick maculae at the margin intensely yellow. Venezuela, in the Province of Caracas; also from Granada (Colombia). Allied to *D. medora* (29 b), but larger. The Colombian specimen shows the band of the forewing much broader and connected with the proximal band.“

albimacula. *D. albimacula* sp. nov. (192 c) from West Colombia (Rio Magdalena) resembles *medora* (29 b), but it is smaller, the yellow inner-marginal spot of the forewing larger, the yellow subapical spots are absent, but there is a large, white subapical spot situate farther posteriorly. The under surface, especially of the hindwings, as the figure shows, is likewise considerably different. I possess *medora* from the same habitat.

D. lygdamis Hew. The ♀ which was discovered by A. H. FASSL in Coroico, Bolivia, 1400 m, resembles the ♀ of *lewyi* (29 e) above, for the black distal margin of the hindwing is much cleft. The under surface corresponds to that of the ♂, but the yellow spots are larger.

Of *D. schausii* Dgn. (p. 101) we subsequently reproduce the upper surfaces of both sexes, of the ♂ also the under surface (192 e). The ♀ has beneath black hindwings, in the centre is a whitish spot, at the base there are 3 rather large red spots, and the costal margin is dusted with a sulphur-colour. The forewing is white with a black apical part in which there are 3 whitish-yellow subapical and 2 similar submarginal spots; the costal margin is also black. The figured specimens are from Peru (Pozuzo).

tolimensis. *D. critomedia*-♀ *tolimensis* Fassl are the ♀♀ of *critomedia* (29 f) from the eastern slope of the Central Cordilleras of Colombia (Cañon del Monte Tolima, 1200 to 1700 m), not showing white, but yellow ground-colouring above.

D. buchtieni Fassl. ♀. „A Bolivian form of *arcadia*; expanse: 55 mm, somewhat smaller than the Colombian ♀ of *arcadia*. All the yellow marking above, particularly the oblique median band of the forewing narrower, as well as the horizontal band of the hindwing narrower and interrupted at the veins. The main difference, however, is that the median band of the forewing is also above not sulphur-coloured, but of a magnificent orange-red, together with the yellow wedge-shaped streak extending along the median towards the base. Beneath analogous to the upper surface with a narrower marking, a very prominent red median band of the forewing, but less prominent silvery dots of the hindwing, the ground-colour of the hindwing not being bright yellow as in the type, but more silvery grey, against which the silvery dots stand out distinctly.“ Coroico, Bolivia, 1400 m; taken in the dense forests of the mountains „where the diurnal lepidoptera are at any rate rare.“ *buchtieni*.

Of *D. lycosura* Hew. (192 e, p. 101) we have subsequently figured the ♂; the ♀ is unknown to us. — **D. ecuadorensis** Niep. The description runs as follows: „Different from the figure as follows above. The white discal spot of the forewing is larger than in the type, and in the middle of the costal margin is a small, white, oblong, round spot. The white colouring of the hindwing is likewise more extensive and at the cell-end there are two white spots. Under surface lighter than in the figure of the type, particularly on the hindwing the light markings are much more extensive and whiter, in the anterior part of the distal margin yellow-speckled patches between the veins. Length of forewings: 28 mm. One ♂ from Oriental Ecuador.“ *ecuadorensis*.

D. macasana Strand from Ecuador (Macas), described according to a ♀, the author takes to be a separate species. The specimen differs from *leonora* ♀ (29 e) by its narrower wings, the discal spot being coherent with the marginal marking, and a somewhat broader black distal margin of the forewing; the under surface has more black and yellow marking than the two ♀♀ before me from Santa Inez (Ecuador). *macasana*.

D. niepelti Weym. ♀ (♂ p. 101) is above white with a broad black apical part of the forewing, in which there are 4 white spots; also the costal margin is broadly black as far as the longitudinal middle of the discal cell, in this black stripe there is a small white longitudinal stripe and before this (at the end of the discal cell) there are 2 small white spots. The hindwing has a broad black apical margin and its posterior half is of the same colour. The under surface corresponds to the upper surface, but is of a more fallow colouring, at the base of the hindwing is a yellowish spot emanating in rays.

D. ela Weym., described according to a ♀ from Colombia, makes the impression of a gigantic ♀ of *pinthaeus*, but the yellow band of the hindwing is very broad, sharply defined and greenish; the red band of the hindwing beneath is very distinct. *ela*.

D. spio Godt. (30 a, ♂). The ♀ has a paler (reddish-yellow) marking and the hindwing exhibits a broad, equally coloured median band, which is also anteriorly bordered with a broad black; the subapical spot of the forewing is parted.

D. astynome paulistana Fruhst. According to the author, the main difference is exhibited by the ♀♀ showing a much narrower reddish-yellow cellular stripe of the forewing and a longer subapical band of yellowish spots and being beneath of a paler greyish-yellow colour. Of the ♀ there exist two forms, one being above chiefly spotted reddish-yellow, as they also occur in Bahia, Espiritu Santo and Rio de Janeiro, and a rare aberration with a yellowish median area of the forewing and a yellowish circumcellular region of the hindwing (♀ form *donia* form. nov.). Patria: Casa Branca, São Paulo.“ *paulistana*, *donia*.

D. astyocha Hbn. (p. 103). FRUHSTORFER regards it to be a species separated from *astynome* Dalm. (30 c). We have therefore had it figured subsequently (192 f).

D. mercenaria versicolora Fruhst. „♀ above of a peculiar yellow hued with pink. ♀ either whitish-yellow or light flesh-coloured (*carnosa* form. nov.). Under surface faded reddish-yellow with two broad brown transverse bands. Patria: Pernambuco (Brazil).“ *versicolora*, *carnosa*.

D. dolorita Fassl. Only the ♀ is known. It differs from *lewyi*-♀ (= *nasua* Fldr., 29 e) by its smaller size, almost entirely black hindwings only showing a white stripe in the costal part, the forewing exhibiting a narrower, very irregularly defined black margin. The under surface is much darker, the large, somewhat dull silvery spots are reduced to the three foremost, the bright yellow wedge-shaped spot extends in a long point towards the base, but about 5 mm before the base it disappears in the dark ground-colour; 3 yellow basal spots are present as in *lewyi*; the other marking of the hindwing beneath is intensely darker and more indistinct than in *lewyi*. The author reports: like all the allied species also *dolorita* is a timid insect flying high up in the mountains and being fond to settle down on projecting twigs in the primeval forests, at sunny places where it basks in the sun with its wings spread out. Colombia, Western Cordilleras, at altitudes of 1800 to 2000 m. *dolorita*.

D. idae Fassl. Above the ♀ (only this is known) resembles that of *medora* (29 b), but the yellow median band of the forewing is narrower and also at the anal margin there is between the first median vein and the submedian a band of the same colour; the black distal-marginal band of the hindwing does not extend to the apex. Much more different is the under surface by the horizontal dark shades which, being connected by the veins, form single yellow ovals and somewhat recall the much smaller *theugenis* (28 h) from Bolivia. Alto de las Cruces, a little beneath the ridge of the Colombian West Cordilleras. In the beginning of January. *idae*.

negrita. **D. mirandola** (29 a) ab. **negrita** Fassl. This form has been established according to a ♂ having been captured during a thunderstorm [on the 3rd of October 1908]; this specimen shows a monotonously black upper surface of the forewing (St. Antonio, Colombia, at an altitude of 1800 m).

altis. **D. altis** Fassl is in both sexes similar to *mirandola* (29 a), but somewhat smaller. In the ♂ only the light (white) spots on the anterior part of the forewing are distinct, the others are dusted with dark, in the ♀ the black distal margin of the hindwing is uniformly broad. The under surface shows dull mother-of-pearl spots. Colombia, Western Cordilleras, at an altitude of 2400 m.

manuelita. **D. manuelita** Fassl is allied to *lygdamis* (29 f), both in the size and marking beneath which resembles that of the *Catasticta*-species. Upper surface white with broad black distal margins, also the discal cell in the ♂ forewing almost entirely filled up with black, in the ♀ with such a stripe along the subcostal; in the apex of the forewing 3 white spots. The under surface exhibits almost the same black marking, and is very much like that of *lygdamis* (29 f). Colombia, Western Cordilleras, at an altitude of 1600 to 2000 m.

D. dejone Hew. ♀ (192 f). The figured specimen is presumably a ♀ of this species. The under surface is blackish-brown with the same marking as above, on the hindwing, however, the brown colouring is much more diffuse. The antennae are coloured like in the ♂. Chiriqui.

jurua. **D. jurua** sp. nov. (192 g). It is not certain whether the specimens figured represent the sexes of one and the same species. The ♀ is very much like that of *tricolor* (30 b), of which neither the ♂ nor the patria are known. The under surface is in both specimens marked and coloured corresponding to the upper surface, though paler, in the ♂ forewing with the modification effected by the scent-organs; both sexes exhibit a series of white spots on the distal margin of the hindwing. From the Rio Jurua.

mechanitina. **D. mechanitina** sp. nov. (192 g). Before me is 1 ♀ from Matto Grosso (Rio Machados) which may belong to another species of which only the male was described. The under surface is like the upper surface, but paler, at the distal margin of the hindwing there is a row of rather large white spots. Antennae very light, in the distal part at the anterior side white, the club yellow.

xanthone. ~~Venez.~~ **D. xanthone** sp. nov. (192 h), the patria of which is unknown, is in the female similar to *mechanitina*; in both sexes the under surface is entirely like the upper surface, but the colours are duller and all the wings exhibit at the distal margin a row of white spots.

Of *D. laia* Godt. we subsequently figure the ♂ (192 g); it originates from Cayenne.

pellucida. **D. pellucida** sp. nov. (192 g) from Jurua may be a species not different from *erythroë* (30 f); the under surface does not show any essential differences. Presumably also *batesi* (30 f) of which a ♀ has been figured belongs to this species; the ♂ lying before me exhibits a complete yellow band of the forewing, a but very narrow yellow band of the hindwing, and besides on the hindwing markings similar to *erythroë*, but before the yellow band black, band-like scaling.

proxima. **D. pinthaeus** (?) **proxima** form. nov. (192 h), captured by Mr. A. H. FASSL in January near Teffé (Ega) on the Amazon River, exhibits a somewhat different shape of the bands on the forewings; the under surface has not a yellow, but white ground-colour, the black median band of the forewing extends uninterruptedly from the costal margin to the distal margin, and the submarginal band is not red as in *pinthaeus*, but yellow like the ground-colour. According to a ♂.

Danaidae.

1st Subfamily: Danaidae.

Hereto we must only add that the American *D. archippus* F. (= *plexippus* L.) has uninterruptedly penetrated in Eastern Asia since the family has been dealt with in this volume. On the Marshall Islands it has now become the most common lepidopteron.

Of *D. erippus* Cr. the larva is black, with broader or finer yellow belts, the thread-appendages black. On Asclepiadeae. The total development from the egg to the imago, according to FERREIRA D'ALMEIDA, lasts for about 1 month.

D. gilippus Cr. Larva likewise of a black ground-colour, in the adult stage with bright yellow belts. On Asclepias. Pupa different from that of *archippus* by the absence of the small golden tips in front at the thorax.

2nd Subfamily: Lycoreinae.

Lycorea halia. Larva whitish-yellow, with numerous brownish-yellow transverse belts; the appendices on the metathorax (3rd ring) are kept in constant commotion by the insect; it was also observed on *Carica popaya*.

3rd Subfamily: **Ithomiinae**.

The **Ithomiinae** in Tropical America are entirely subject to the laws governing all the groups of insects which do not like to fly or are bad flyers in this woody region: almost every greater part of a forest, the river-basin of almost every little river has a special mode of marking from which the members flying there and taken at exactly the same locality differ to a remarkably little extent. One may often travel for miles and miles without finding a certain species of *Ithomia* or *Pteronymia*, which may then be suddenly swarming in a surprisingly great number of specimens at an entirely circumscribed place. Thus I once saw on a bush only 2 m high near Santos more than 20 specimens of *Melinæa paraiya* of which I had before not discovered a single specimen in spite of having been roaming about for many days. Scarcely any specimen of this species flew away from the bush, until all of them were captured: such a behaviour is only met with in well-protected lepidoptera crowded together on confined habitats (in Europe in the genus *Zygaena*). The incredible laziness of these diurnal lepidoptera from the subfamily of the **Ithomiinae** may be concluded from a remark of FERREIRA D'ALMEIDA in his very nice and biologically most interesting book: „Études sur les Lépidoptères du Brésil“ (Mélanges lépidoptérologiques) on p. 71, according to which the imagines resting on the blossoms or tips of the branches may be simply taken away with one's fingers; an observation which I can substantiate for a great number of species of the group. A necessary consequence of this character is the so-called formation of colonies or subordinate races, as by the very rapidly succeeding generations (each generation mostly does not need more than a month for its development) a certain pattern of marking is quickly fixed at a habitat to such a degree that even minute deviations from it number among the very greatest rarities. We may then find at the next habitat of the species a somewhat different colouring, though it shows here the same constancy as the former at the other habitat. I have considered it incorrect to denominate these mostly insignificant though constant deviations, as it has been done by others in other cases (such as in the *Erycinidae*). This method if being consistently performed, would have to increase to an infinite amount, and in composing this chapter on p. 116 to 165 the compiler was also led to confine the denomination to notoriously zoographical races and to avoid the denomination of subordinate races. The compiler has carried this out very meritoriously, and it seems that up to this day this excellent example has also prevented later describers to corrupt his succinct delineations by hair-splitting processes. May this chapter be also in future exempt from the denomination of transitory forms effacing the exact boundaries, without checking the admittance of really maintainable races and species with the impending opening up of South America *).

Mechanitis lysimnia F. (34 b). Larva on *Solanum arrebenta*; anteriorly very much narrowed with a small head; adult larva 31 mm long, of a bright yellow, across the dorsum 2 greyish-blue or greyish-green longitudinal bands; head black.

Pseudoscada. For the form *Ps. adasa* Hew. p. p. (41 c) FERREIRA D'ALMEIDA introduces the name **diversivoca** and places the species to *Dismenitis*. — For the other figure of *adasa* by HEWITSON (Exot. Butt. Vol. 4) the same author establishes the species **pseudodiversivoca**: smaller, the forewing more pointed, the demi-band and marginal band straighter; the upper discocellular is absent, the lower more curved. Southern Brazil. *diversivoca.*
pseudodiversivoca.

Ceratinia euryanassa (35 b). Larva on *Datura arborea*, in the adult stage up to 3 cm long, with a yellowish-brown head, the body with bright transverse stripes, ventrum deep green; pupa yellowish-brown, the wing-cases of a dingy white, marbled with dark, the pupa itself with numerous small dark spots and markings. FERREIRA D'ALMEIDA bases a new genus on this species: **Placidula**.

For *Cerat. daëta* Bsd. the same author introduces the genus **Mansueta**. The ♀ lays the eggs singly on *Solanum argenteum*. The adult larva is 23 mm long, above of a dingy greenish or bluish grey, beneath whitish, on the sides with a yellowish stripe-like colouring, across the dorsum transverse wrinkles of a deeper colouring, particularly the anterior part of the larva very much wrinkled.

With the newly established genus **Rhadinoptera** Ferr. d'Alm. its author combines a number of species that were before ranged in various other genera to which they had been placed according to the neurulation, such as *Ceratinia*, *Ithomia*, *Hypoleria*, *Heterosais*, *Pteronymia* etc. The first form of this series is:

Cerat. eupompe Hbn. (35 d). Larva on a Solanea; in the adult stage 25 mm, above greyish-green, on both its ends whitish, with transverse wrinkles, thoracal segments spotted dark, ventrum lighter. — Pupa green with small metallic spots.

*) A similar behaviour as we have ascertained for the insularly confined habitats of the neotropical wooded districts for many resident or weak-winged species of lepidoptera, occurs in mountainous species at such places where the alpine habitats are isolated by interposed valleys impassable to the alpine inhabitants, as for instance in the *Parnassiae* everywhere where these dwellers of mountains are. The one species *P. apollo* was provided with more than 100 names, more than 80 of them with the statement of geographically defined habitats. If the denomination is not checked in analogous cases, certain groups in South America will be loaded with a ballast of names that renders the orientation difficult instead of facilitating it.

- ellariformis*. **Napeogenes ellariformis** Strd. is quite similar to *Ithomia ellara* Hew. (37 e) but the median hyaline band of the hindwing extends into the cell, the veins separating the hyaline spots are not so thick black, the white marginal band spots are larger. From Peru.
- anteëlla*. **Nap. anteëlla** Strd. is almost like *Ceratinia antea* Hew. (35 d), but somewhat smaller, the blackish marginal band relatively somewhat broader, more blackish-brown than jet-black, the small white spots embedded there in larger and increased in number, as there is another one in the anal angle of the forewing; the marginal band of the forewing forms a small tooth at the veins 3 and 4. Described according to 1 ♂ from South East Peru.
- hemisticta*. **Nap. hemisticta** Schs. from Costa Rica forms an exact imitation of the Costa Rica form of *Hyposcada adelphina* (38 c), exhibiting on the forewing likewise 2 red-brown basal rays and several rows yellowish-white spots in the distal half of the wing; it thereby also resembles *Ithom. plaginota* (37 b), *Nap. amara* (35 d), *Cerat. callispila* (35 a) and some more lepidoptera from Costa Rica in the company of which it flies there.
- Ithomia drymo* Hbn. (37 g). Larva likewise on Solaneae, in 2 forms, with a red-brown or metallic lustrous bluish-green ground-colour. Pupa light green, at the wing-cases lighter with but 2 small golden spots at the sides of the capsule of the head. (FERREIRA D'ALMEIDA).
- bolivari*. **Ithom. bolivari** Schs. is very much like *patilla* (37 f), but the black wedge-shaped spot in the centre of the forewing has such a broad base that it occupies a whole third of the costal margin. Costa Rica.
- Hypoleria oreas* Weym. (41 a). Larva on Solaneae, in its juvenile stage white, in its adult stage 22 to 23 mm, with a somewhat flat body, of a pure yellowish-green with a fine dorsal line, laterally lighter, on the ventrum whitish; head green, on each side with a short, curved longitudinal row of black granulations. Pupa green, very much like that of *Ith. drymo*.
- Heterosais edessa* Hew. (41 g). Larva dull bluish-white, with a somewhat flat body; on the sides of the dorsum rows of darker or blackish-spots; across the dorsum darker transverse wrinkles. Pupa uni-coloured green, at the head golden dents with a blackish tip; larva on Solaneae.
- peruvicola*. **Leucothyris peruvicola** Strd. Like *Leucoth. solida* Weym. (38 g), but the hyaline band of the hindwing not expanded towards the anal margin, equably 5 mm broad, the marginal band only showing traces of 1 small white dot. The light spots are mostly somewhat larger; in the apical part of the forewing 3 small white spots. *completa* Hsch. differs from it by the white dots in the black marginal part being distinct there. South East Peru.
- Pteronymia euritea* Cr. (40 d). Larva on various Solaneae, of a pure green, with a yellow lateral stripe, across the dorsum many black transverse lines. Pupa like that of *Episcada clausina* (39 d), of a lustrous yellowish green, across the dorsum silvery transverse spots with a golden lustre, sometimes there are brownish markings exhibited; pupal stage lasting for about 10 days.
- Pteronymia sylvo* Hbn. Larva above greyish-green with dark, oblong transverse spots, ventrum yellowish-white, dorsum and lateral line yellow; some specimens also exhibit on the dorsum darker transverse markings. Pupa brownish, of a green lustre, with small metallic spots. On *Solanum argenteum* and allied plants.
- fumida*. **Pteron. fumida** Schs. Colouring and markings something like in *Pt. laura* (40 d), but very much larger, about the size of *denticulata* (40 b), easily discernible also by the absence of the jet-black cell end spot of the forewing which is distinct in *laura*; the transverse vein is only situate in a dark shade. Thereby the species becomes similar to numerous other species flying at the same place, such as *Callithomia hydra* Fldr., *Dircenna klugii*-♂ (36 e) though more in its form *chiriguensis* Hsch. etc. From Carillo in Costa Rica.
- godmani*. **Pteron. godmani** Schs. According to W. SCHAUS the two figures of *simplex* Salv. 40 b are not the different sexes of one species, but the form figured as a ♂ with the narrow, comma-like bent cell-end stripe is a different species and is therefore denominated *godmani* Schs. Common in Costa Rica at altitudes of more than 3000 ft.
- Episcada clausina* Hew. (39 d). The larva spins together some leaves of its food-plants (Solaneae) and in this cover it also uses to pupate. In its adult stage it is 16 to 17 mm long, above greyish-green, laterally tinted yellow; lateral stripe whitish, interrupted by small yellow spots; head blackish, dorsum with transverse wrinkles. Larva sometimes with a blackish lateral band. Pupa green or red-brown with silvery wing-cases.
- nebula*. **Episcada hymenaea** Prittw. (39 e) ab. **nebula** Ferr. d'Alm. On the subcostal and beneath the lower cell-wall a rusty yellow longitudinal ray. — ab. **stratonicis** Ferr. d'Alm. The yellow ray below the costa is present, but that below the median is absent. — Larva of *hymenaea* (39 e) 22 to 24 mm long, above greenish-grey with a white lateral stripe, which is interrupted by small yellowish spots, above it a blackish longitudinal shade, the transverse wrinkles dark green; on Solaneae. Pupal stage 10 days. The imagines fly in Southern Brazil particularly in winter.
- umbraticola*. (*Rhadinoptera*) **umbraticola** Ferr. d'Alm. Colouring and marking of *Heterosais nephele edessa* Hew. (41 g), but the demi-band at the cell-end of the forewing wedge-shaped, the white spot behind it distinct, the mar-

ginal band of all the wings dotted whitish. Beneath this marginal band is rust-coloured, bordered with black. Described according to 1 ♂ from Rio taken in April. — For this species the group *Pigritia* was introduced by the author FERREIRA D'ALMEIDA. — **genytilis** *Ferr. d'Alm.*, for which the author has likewise established a group (*Languida*), is entirely like *umbraticola*, but somewhat smaller, the white marginal spots of the forewing well visible, but those of the hindwing indistinct. One ♀ taken in November in the State of Rio. genytilis.

Satyridae.

Antirrhaea ulei *Strd.* is a species from Roraima in Venezuela, with an expanse of 90 mm, with a dark band of the forewing extending through the cell, behind which there are 6 dirty white spots in a greyish band. ulei.

Taygetis weymeri *Schs.* (193 d) from Costa Rica somewhat recalls beneath *T. umbinata* (45 b), but it is easily discernible by the straight, not angled margin of the forewing, which extends like in the smaller *blanda* (45 d). As in *blanda* also in *weymeri* ♀ the postmedian transverse line is distally bordered with whitish, though bent in an obtuse angle, whereas in *blanda* it is almost straight. weymeri.

Tayg. celia. As f. *magna* *Ferr. d'Alm.* a large form is described beneath resembling *cleopatra* (45 c), approximating the form *haenschi* (45 b), according to a ♀ which probably originates from the State of Rio in Brazil; the exact habitat is not stated. magna.

Tayg. fulginia *Ferr. d'Alm.* has the size and approximate shape of *T. rectifascia* (45 a), but the under surface is not so monotonously dark brown, but with more abundant and brighter markings. Established according to a single ♂ taken in October at a swampy place in the State of Rio. fulginia.

Euptychia agnata *Schs.* (193 d) from Costa Rica, resembles *juani* (49 a), but it is much larger. The ground-colour beneath is more yellowish-brown, the discal bands are connected before the posterior margin of the hindwing, above the large eye between the median veins there is a bean-shaped spot. agnata.

Eupt. drymo *Schs.* (193 a) is easily recognizable by the yellowish-red lighter part in the disc of the forewing. The two large eye-spots of the hindwing beneath are proximally bordered by two dark arcuate stripes. Costa Rica. drymo.

Eupt. hesione *Sulz.* (46 d). Eggs black, globular. Larva on Gramineae, in its adult stage about 30 mm long, green, with white granulations and pinkish-red anal apices; the 3 first rings on the dorsum brownish. Pupa yellowish-green, yielding the imago after 12 days.

Eupt. byses *Godt.* Egg globular, whitish. Larva on grasses, whitish green with a more distinctly green median line, on the dorsum with transverse wrinkles and covered with whitish granulations. Pupa 13 mm long, on the thorax with a keeled hunch, greenish white with a slight lilac reflection. — **bimaculata** *Ferr. d'Alm.* is a female form of this species exhibiting beneath a yellow costal spot on the forewing, yellow instead of white apical dots, in the hindwing only extinct undulate streaks, but instead of it a white, dirty discal spot; described according to 1 ♀ (aberrative?). bimaculata.

Eupt. pavunae *Ferr. d'Alm.* approximates *harmonia* (48 b), but beneath it is darker brown, at least in the basal half, the two dark marginal lines slightly undulate. Forewing with 4, hindwing with 5 brown dots, the discal transverse lines straighter. Rio, in swampy places near the ocean, at some places not rare. pavunae.

Of *Eupt. herse* *Cr.* (49 e) a form is described: **bellatula** *Ferr. d'Alm.* from a swampy district of the State of Rio, the diagnose of which also fits normal specimens and is apparently only distinguished by a bright violet reflection above. This form as well as the type exhibit a remarkable harmony with certain species of the Erycinid genus *Euselasia*. bellatula.

Eupt. arnaea priamis *Ferr. d'Alm.* is a form from the State of Rio, in which the very bright lustrous blue of the hindwing passes over to the forewing across the proximal margin of it. Beneath the distal transverse line is slightly angular at the 1st median vein. priamis.

Eupt. suivalens *Dyar* (193 f) is apparently not particularly similar to any other *Euptychia*; in its size and exterior it is somewhat like *calixta* (48 c), but the under surface is differently marked, in the anal part of the marginal area discoloured ruddle-red, the ocelli scarcely recognizable except 2 at and above the middle of the margin, the transverse line of the hindwing coarsely dentate. Mexico. suivalens.

Eupt. pertepida *Dyar* (193 f). Above and beneath suffused with a dull purple brown; above there are only before the middle of the margin on the hindwing 2 small black punctiform spots, beneath there are besides 2 largely dentated transverse lines through the disc. Mexico. pertepida.

Chionobas osleri *Skinn.* is a newly described variety from the *alberta*-group of *Ch. tarpeja*. osleri.

Catargynnis macasica *Strd.* is very much like *pholoë* (57 d) and only differs by the orange spots of the forewing above being larger and the under surface being somewhat more variegated, especially decorated with larger silvery spots. macasica.

Catarg. dryadina *Schs.* (193 e) from Costa Rica is a little like *gigas* (57 c) or *loxo* (57 d), but the hindwing above has no orange margin, and beneath the ocelli are larger, more variegated, especially also on the forewing. dryadina.

roraimae.

Pedaliodes roraimae *Strd.* Beneath similar to *prosa* (53 f), but the ground-colour is darker, in the forewing almost black, in the hindwing very finely marbled with brown. Transverse band not so deeply dentated, but more finely serrate-dentate than in *prosa*. Expanse of wings: 49 mm. Venezuela.

maria.

Ped. maria *Schs.* Above dark brown with a still darker marginal line. Beneath the same, the lines darker; in the cell a median arcuate line, behind it a line being undulate before the proximal margin, somewhat oblique to the costal margin. In the hindwing an antemedian line slightly indented at the proximal margin, and a postmedian line being proximally bordered with dark red, behind which there are 3 black ocelli encircled by yellow and containing a white dot. — ♀ not quite so dark, the lines and 1 or 2 ocelli also above visible, the postmedian line proximally shaded with dark red. Hindwing beneath with a small ocellus towards the costal margin and yellow dots between the veins 4 and 6, the ocelli otherwise as in the ♂; ♂ 43, ♀ 45 mm. — From the Volcano Sa. Maria in Guatemala, taken at an altitude of 4500 ft. in April, July, October and November.

Erycinidae.

To the „Additions“ on p. 726 to 728 we add yet **Eucorma sanarita** (113 B e) which was in the meantime described by W. SCHAUS, having been discovered in the Brazilian Province of Minasgeraes and figured according to a specimen sent by Mr. ZIKAN. Under surface like above.

To *Lymanas thyateria* we have to remark that FASSL took in copula with a typical ♀ corresponding with our figure 131 h a similar lepidopteron (113 B e) as was hitherto ranged with the genus *Estemopsis* as being allied to *inaria*.

Nymphalidae.

Genus Colaenis.

Col. euchroia. The names of the forms *telesiphe* Hew. (p. 400, line 7 from below) and *tithraustes* Salv. (line 5 from below) have been mixed up with each other both in the text and the table belonging to it (84 d).

Genus Melitaea.

M. chara *Edw.* (88 f) COCKERELL considers to be the eastern form of the subalpine or boreal *minuta* which flies at much greater altitudes.

fulvia.

M. leanira fulvia *Edw.* forms a transition to *wrightii*; the hindwings are beneath whitish-yellow instead of tan-coloured. The form is mentioned by COCKERELL from New Mexico.

Genus Phyciodes.

dora.

Ph. dora *Schs.* from Costa Rica entirely resembles *levana* (88 h) above, but on the hindwing a chain of ochreous rings extends between the ochreous-yellow median band and the margin.

Ph. coela *Drc.* As the ♂ of this species, the figure (91 c) and description (p. 444) of which seems to represent a ♀, W. SCHAUS figures a lepidopteron from Costa Rica, almost all the specimens of which exactly resemble the ♂ of *sestia* (90 g) except the brownish-yellow transverse band of the hindwing being a little broader and of a more fiery colour.

Ph. phlegias *G. & S.* The ♀ of this species, the ♂ of which we have figured 99 b by the name of *platytaenia*, is somewhat larger, the spots and bands are broader and bone-coloured, so that it approximately resembles the upper surface of *tulcis*-♀ (90 c).

metharmoi-
des.

Ph. metharmoides *Fassl* (102 C a as *metharmeoides*) from Teffé (Ega) on the Amazon River, is one of the largest species of this genus. The under surface corresponds to the upper surface, but on the forewing the colours are duller, and the hindwing shows a series of white marginal spots.

pseudocole-
mina.

Ph. pseudocolemina *Strd.* in its shape and marking is very much like *ithomoides* (90 k); the marking of the forewing is almost the same, but it is without the yellowish-brown inner-marginal stripe, whereas the hindwing above is almost without markings. Colombia.

sticta.

Ph. sticta *Schs.* (192 h) is the exact image of *Napeogenes hemisticta* with which it flies together in Costa Rica. It approximates *Ph. nigripennis* (90 i), but it has the shape of the wings of *sestia* etc. The distal half of the forewing more intensely and abundantly spotted whitish, of the hindwing only the anal half is yellow.

Genus Nessaea.

juventia.

Nessaea obrinus faventia *Fruhst.* „♂. Above on the forewing with a green oblique band narrowed and rounded off both costalwards and analwards. The yellow area of the hindwing, however, is much more extensive than in specimens from Surinam. Under surface much paler green with quite unnoticeable brown longitudinal bands the distal (submarginal) one of which is altogether absent. Patria: Matto Grosso.“

Callithea boyi (102 C d). This new species was discovered by Mr. CARLOS BOY in September 1922 near Mujo (Lower Amazon); before me was a ♀ which has been figured. It is allied to *batesii* (99 f); the differences above are to be seen from the figures, the under surface of the hindwing, however, is not verdigris as in *markii*, but of a delicate grey which is lighter in the larger distal half; yellow colouring is only noticeable in a spot at the base of the wing and in a stripe not coherent with the basal spot, at the proximal margin; the four rows of black spots consist of almost equally large spots, the proximal three rows being composed of smaller spots than in *batesii*, whereas the submarginal spots are larger and distinctly crescentiform. The under surface of the forewing resembles more that of *markii* (99 f), but the basal yellow colouring occupies a larger space, the distal half is brightened up in the centre, and there are only 3 black spots, the anterior one of which is very small, whilst the posterior one is only indicated by some scales.

Callithea batesi munduruca Fassl. „An extremely eastern form of *batesi*. Mr. OTTO MICHAEL, already years ago near Itaituba, took 3 of it which Dr. STAUDINGER, owing to the absence of the ♂♂ belonging to them, determined to be questionable ... of *markii*, until I succeeded 2 years ago in capturing also ♂♂ at several places of the right and left banks of the Tapajoz. They are almost invariably one third smaller than those of the *batesi*-type from Teffé. Above much more reddish-violet; the verdigris margin on both wings is narrower, but more prominent and proximally more distinctly defined than in *batesi*, at the costal margin of the forewing extended more proximally. The yellow basal spot on the forewing above is bent more proximally, but in the hindwing it only fills up the base of the cell, whereas in *batesi* it almost occupies the proximal half of it. The violet hue on the yellow spot is less intense than in *batesi*, whereas the white fringes of both wings are much stronger. Distal half of the under surface lighter silvery, almost invariably the distal 4 marginal dots in the apex of the forewing well developed, particularly the lowest, whereas in *batesi* they are almost invisible and almost entirely covered by the verdigris tint. ♀: ground-colour above black, without any trace of a greenish reflection (in *batesi*-♀ always with it); the verdigris distal margins above and the under surface of a purer and lighter silvery lustre; body, particularly ventrum beneath almost purely white (in *batesi* grey; the other differences like in the ♂♂. — Itaituba, Miritituba, Cachcêra I, Concessão and Monte Christo on the Rio Tapajoz, in single specimens and rare; the ♂♂ extremely rare and always flying high up. Both sexes do not react upon any bait. „This *Callithea* is a double of the *Phalcidon*-form *Agrius anaxagoras* likewise occurring on the Tapajoz.” — **aimeeana** Fassl. „♂ mostly smaller than *batesi*, but invariably larger than *munduruca*-♂. Above similar to the latter, but the green marginal bands of both wings much narrower and more extinct, and the uppermost 3 submarginal ocelli in the apical part of the forewing showing through above from beneath, and the extreme apex of the wing shaded with black from outside. ♀ like that of *batesi*, but at once discernible from it by the double row of black submarginal ocelli of the forewing beneath. Manicore on the Rio Madeira, captured in small numbers; the ♀ is very rare.” (FASSL.)

Genus *Catagramma*.

C. discoidalis Guen. (p. 494) = *brome* Bsd. (101 B b).

C. mena Stgr. (p. 494). The original description entirely fits *aegina* Fldr. (101 B c). We were unable to ascertain whether it is a local form, because there are no specimens from Peru (Chanchamayo) at our disposal. — **lamprolenis** *subsp. nov.*, from Bolivia (Rio Songo, 750 m, discovered by A. H. FASSL) is somewhat larger than specimens from Ecuador (Macas), has a somewhat narrower yellow band of the forewing and a smaller blue spot on the hindwing exhibiting also a duller and deeper lustre. — In **bella** *subsp. nov.* from Eastern Colombia (Villavicencio, 400 m, A. H. FASSL) the blue spot on the hindwing is still smaller and the veins crossing it are remarkably scaled black. The ♀ has a rounder shape of the wings, the ground-colouring is duller, and the yellow band of the forewing is broader and lighter than in the ♂.

C. transversa *sp. nov.* (102 C e) is before me in a ♂ from „Bolivia”. The marking above is to be seen from the figure. The forewing beneath is like in *lyca* (101 B c) except the different shape of the yellow band, whilst the hindwing beneath is conspicuous for the great extent of the black colouring; all the yellow bands are narrower than in the allied species, particularly the otherwise very broad second band (counting from the margin) is very narrow and scarcely half as broad as the other yellow bands; the yellow marginal band is in the posterior half replaced by a greenish (not blue) one; the bluish-white median spots are very small, the anterior group containing two, the posterior group three spots, whereas the fourth (at the proximal margin) is replaced by a small blue dot.

C. hystaspes F. is on p. 494 misprinted into *hystaptes*.

C. platytaenia Rüb. (102 C b) is considerably different from all the other species of this genus by the shape of the yellow band of the forewing; the under surface resembles that of *denina* (101 B b). Western Colombia (Rio Dagua).

Cat. hydarnis Godt. (p. 496) we have subsequently figured (102 C a). About the ♀ of *C. excelsior michaeli* Stgr. A. H. FASSL writes: „The extremely rare ♀ of *michaeli* of which I only took 2 specimens is very much like *C. excels. mauensis*-♀ described above, except the yellow bow of the forewing being exactly as shortened and blunted off like a club as in the ♂. The forewing is without a reflection, the hindwing of a lustrous sky-blue colour.“ — The said author presumes that the red-banded forms of this species form a separate group the occurrence of which is confined to the northern bank of the Amazon River. — *coruscans* Rüb. (102 C c) differs from the other forms of it by the magnificent blue lustre of the whole upper surface and by the shape of the yellow band of the forewing. Matto Grosso (Carumba). — *inferior* Btlr. from Peru is quite similar to *speciosa* (p. 495), but the band of the forewing does not begin at the base of the wing, but the basal part of the forewing remains black. — *mauensis* Fassl. „The new *excelsior*-form from the Rio Maues has in both sexes a much narrower yellow bow notched by the veins. The magnificent blue lustre with a more violet tint is intensified in the distal margin of the hindwing, without being proximally distinctly defined to a light blue spot. The somewhat lighter ♀ with a black forewing without a reflection differs very much from *excelsior*-♀ by the hindwing being sky-blue and lustrous as far as the base and being finely interrupted by the black veins like a net. The magnificent blue colouring intensifies towards the distal margin. Several couples from Mauès and Massauary; a rare and most beautiful insect.“

C. arirambae Ducke *) from the Campos do Ariramba (to the east of the Central Trombetas), from an altitude of about 280 m, is „not rare in the little forests of the banks of larger brooks“. The ♂ on the black upper surface shows a deep blue reflection, the ♀ does not. The under surface of the forewing corresponds to the upper surface, but the colours are duller, and there is a blue submarginal line; the under surface of the hindwing is similar to that of *excelsissima* (101 B f), but the yellow bands are narrower; the white subapical spots are larger than in this and so near to each other that they almost form a band. — *albifasciata* subsp. nov. (102 C c), discovered by Mr. A. H. FASSL near Manaus, differs by the white subapical spots being confluent and forming a complete band only parted by the black veins.

C. sorana splendida Rüb. shows a more intense blue lustre above, and the red markings are more reduced: the band of the forewing is narrower, the red basal part shorter, on the hindwing stunted to a small spot parted by the black veins; the under surface corresponds to the upper surface. Bolivia (Rio Songo, 750 m).

C. strympli Fassl. „This new form belonging to the *texa-lepta* group is above most similar to the Central Colombian *C. texa* Hew. (101 B g), but the red discs of both wings are distally surrounded by a light blue reflecting zone, whereby it entirely resembles a miniature *Agrias claudia michaeli* from the same habitat. The under surface is at once and conspicuously discernible from *texa* by the red spot of the upper surface appearing beneath light orange, and by the rows of blue dots and the central ocelli being very distinctly visible in the black filling and much larger and of a light sky-blue colour.“ Habitat: on the right bank of the Tapajoz, above Monte Christo, a day's trip below Itaituba. — „On my Hingu-expedition I took, 30 km below Alta Mira, a ♀ of *Catagramma* which I might regard to belong to *strympli*-♀. All the red above is orange, the subapical band white; the disc of the hindwing is only indicated by an oblong discal spot of yellowish-brown scales. The under surface entirely corresponds to that of the ♂ described above, but it is in all its parts less intensely coloured and in all its light places much paler.“

C. astarte ab. *preta* Fassl ♂ ♀. „This aberration occurring amidst the types is very conspicuous by all the three blue ocelli parted by the radial yellow median streak on the hindwing beneath being entirely absent, whereby the insect looks beneath quite strange. 1 couple from Obidos, Amazon.“ — *obidensis* Fassl ♂. „Another conspicuous aberration which has a quite normal under surface except the entire absence of the yellow horizontal median stripe separating the 3 central ocelli of the hindwing from each other. I take also this form of which I took 2 equal specimens near Obidos only to be an individual aberration of *C. astarte*.“

*C. peristera coeliger*a Fassl ♂. „This insect looking like an „aberration of a cold climate“ has all the blue dots and the blue submarginal border of the hindwing beneath flown together, so that a large sky-blue disc is produced almost covering the whole hindwing, by which the insect looks very singular.“ Discovered near Santarem — Taperinha.

*) Mr. H. STICHEL, at Berlin, comments (in: Neue Beiträge zur Insektenkunde Vol. I, No. 2, p. 15, of June 30th 1916) upon my having left out this species in dealing with this genus on p. 493 seq., „although it has been published 2 years before the edition of the elaboration of this genus . . .“ (July 1915). At that time this description was indeed still unknown to me, but it seems that also Mr. STICHEL only knew it after the 1st of January 1916, or else he would have already expressed his critic in the No. 1 of his afore-mentioned journal which was published on that day. — Mr. STICHEL besides reproves the absence of „*Catagramma*“ *branicki* Oberth., although it is mentioned on p. 502 as *Callicore branicki* and also figured on t. 102 B. Mr. STICHEL only did not recognize the generic position of this species, or else he would not have missed it in the genus *Catagramma*.

C. texa-texotitania Strand. The author says: „A ♂ from South East Peru to a certain degree forms the transition from *C. texa* Hew. to *titania* Salv. Above like *texa* as it is figured in SEITZ' work, except the red basal area being in the costal half of the wing less far extended towards the apex, so that the costal margin of the area is here only about 9 mm long, whereas in *texa*-figure 101 B g in SEITZ it is about 13 mm long; moreover, the red area is besides diminished by a black dorsal-marginal band almost touching the anal angle. In the hindwing there are near the anal angle two minute, light blue sublimbal spots. — The under surface agrees better with *C. titania*; but from the figure in SEITZ it differs by the red area reaching the anal angle and a light costal band of the forewing being only present in the basal quarter and only linear, whereas in the hindwing of my specimen the metallic markings are more bluish, the yellow sublimbal band more distinct, the following yellow band distally not interrupted midway and being there almost contiguous with the oblique median transverse band. — It is rather a form of *texa* than of *titania*, since the contours of the wings are like in *texa*. Perhaps a distinct species.“ *texotitania*.

C. hydaspes aiaces Fruhst. „♂ above very closely allied to *hydaspes delmas* Fruhst. (p. 599) from Paraguay. The red band of the forewing, however, is broader, the blue area of the hindwing still more reduced. Under surface: the yellow preapical band of the forewing broader than in *hydaspes* from Espiritu Santo. The yellow parts of the hindwing still a little more extensive than in specimens from Paraguay, the black spots and bands accordingly reduced. The four pupils in the black median area of the hindwing predominantly yellow instead of blue. Patria: Rio Grande do Sul, to the north distributed as far as São Paulo in Brazil.“ *aiaces*.

C. pitheas pallescens Fruhst. „The red spots on the hindwing above longer, the oblique band of the forewing narrower than in *C. pitheas* Latr. (102 A b), the ♀♀ besides with a distinct, yellowish preapical band of the forewing, which is absent in *pitheas* from Colombia. The black ocelli of the hindwing as a rule smaller than in *pitheas*. Patria: Venezuela.“ *pallescens*.

C. codomannus paulistanus Fruhst. „♂ and ♀ very closely allied to *selima* Guén. (p. 494) from Minas Geraes, from which, however, it is at once discernible by the still more reduced red colour on the hindwing above and the almost disappearing reddish-yellow preapical spot of the forewing. The under surface is more different, e. g. the yellow preapical spot of the forewing is scarcely half as broad as in *selima*, the yellow submarginal band of the hindwing is reduced to about a third of the extent of *selima*, accordingly the black band is widened and the discal spots are contiguous. Patria: São Paulo.“ *paulistanus*.

C. lyca maroma Fruhst. „♂ differs from *lyca* as DOUBLEDAY and SEITZ-RÖBER figure it (101 B c) by a longer, more uniformly broad and more conspicuous orange band on the forewing above. The blue reflection of the hindwing, however, is considerably reduced. The under surface is most similar to *lyca aerias* Godm. (p. 598), . . . but the bluish-white pupils of the black discal area of the hindwing are larger. Patria: Colombia, no exact habitat mentioned.“ — **exultans** Fruhst. „Above most closely allied to *aegina* Fldr. (101 B c) from Ecuador with a much broader orange band of the forewing and a more extensive blue reflection on the hindwing above. The black submarginal band of the hindwing beneath narrower than in *aegina*, as FELDER figures it. Patria: Bolivia.“ *maroma*.

C. eunomia triteia Fruhst. „Distinguished from *C. eunomia* Hew. (101 B h) from „Quito“ by the narrowed red area of the forewing being confined to a vertical band of a finger's breadth, since a black basal zone advances as far as the middle of the cell. Patria: Ecuador, Hazienda Anna Maria, Querindo.“ *triteia*.

C. pygas catharinensis Strand. On the hindwing beneath the black postmedian band which otherwise exhibits blue median spots, is in the centre yellow like the ground-colour, at the proximal margin at most very slightly bluish. — ab. **sublimbalis** Strd. in the hindwing above does not show any bluish-white sublimbal spots, the length of the forewing is only 22 to 23 mm, and the light subapical marking of the forewing is very much reduced. Santa Catharina. *catharinensis*, *sublimbalis*.

C. pyracmon Godt. E. STRAND, in dealing with a ♀ of this species from an unknown habitat which he connects with the figure on table 101 B h having been done according to a ♂, proposes the eventual name **pyracmonides**. The specimen the upper surface of which has been figured originates from Surinam. *pyracmonides*.

C. aphidna aphidnella Strd. According to a ♂ from Peru showing slight differences from the original description, the author introduced this eventual name. *aphidnella*.

C. zerynthia Burm. Of this species I have neither seen a specimen nor obtained a description; it is presumably synonymous with another species; in KIRBY's Catalogue of the Diurnal Lepidoptera and its Supplement it is not mentioned. Mr. H. STICHEL in a letter presumes it to be a subspecies of *sorana*. *zerynthia*.

Genus **Perisama**.

Peris. insignis sp. nov. (102 C a) from West Colombia (Rio Dagua, 2000 m, A. H. FASSL) is distinguished by the broad golden green area of the forewing above. The hindwing beneath resembles that of *humboldtii* (102 A e), but the yellow is much paler and the black dots are arranged in a straight line; the under surface

of the forewing is greyish-black, the basal half of the discal cell greyish-yellow, the apex of the wing yellow like the hindwing; at the costal margin in the centre of the black area a white, long-extended spot, and between this and the yellow discocellular spot a small blue stripe. Also similar to *tryphena* (102 A f), particularly above, but the under surface has no blue markings and on the hindwing the distal black line is much less dentate and stronger, and the centre shows 5 intense black dots.

P. eminens Obth., on p. 498, was considered to be an aberration of *oppelii*; in the meantime it was found out to be a distinct species and we therefore figure it (102 C b). The species occurs in Northern and Central Peru.

pseudolebasi. *P. lebasii* Guér. The form figured 102 A g has been denominated by EMBRIK STRAND **pseudolebasi**; the author presumes it to be a species different from *lebasii*. This would be correct, if — what is not proved — HEWITSON's figure represents a typical specimen. — Moreover, E. STRAND established the aberration of *lebasii*: **derufata** which he describes as follows: „The specimen before me differs from HEWITSON's figure, by the following marks; the band of the forewing is narrower (about 2 mm broad), on vein 2 narrowly interrupted, and the anterior proximal angle is extended towards the basal longitudinal streak which, however, it does not touch; on the hindwing beneath the red costal-marginal streak reaches to the distal transverse line; the forewing beneath is not marked red, but the terminal half of the cell is blue and separated from the greyish-whitish basal part merely by a small dark diffuse patch, the other blue markings of this under surface being similar as in the figure cited, though less distinctly defined.“ Colombia. — **dividens** *subsp. nov.* from Western Colombia (Rio Magdalena) has a very narrow magnificent band being broken up into single spots, and a broad marginal band of the hindwing.

zyxata. *P. diotima zyxata* Fruhst. „Peru, Pozzuzo. ♂ of a larger habitus and above with much larger, greenish-blue intramedian spots than *diotima* (102 B a). Under surface darker, the neat red submarginal line of the hindwing is brighter. — *zurita* Fruhst. Ecuador. An excellent form, recognizable by an ultracellular, supplementary blue intramedian spot of the forewing which is united with the bluish-grey cellular streak. Under surface: the red cellular spot of the forewing is smaller than in the Peruvian and Bolivian forms, sometimes almost extinct, but invariably faded. Forewing besides characterized by another white costal spot and two greyish-brown blurred intramedian maculae. — **demata** Fruhst. Ecuador, Macas. Whilst *zurita* most probably originates from the Pacific part of the Cordilleras of Ecuador, *demata* is a vicarious form from the Amazon part of the Andes of Ecuador. It originates from the Rio Upano, a source of the Amazon. The blue spots above as in *zurita*, but smaller, darker. The large cellular spot on the forewing beneath, however, again very large, equalling that of *zyxata* Fruhst. from Peru. The white preapical spot still more prominent than in *zurita*, the hindwing above, however, with a blurred marking.“

P. cardases Hew. (102 B b), according to FRUHSTORFER; is a species different from *diotima* (102 B a). Ecuador.

cecidina. *P. cecidas cecidina* Fruhst. „Peru, Cuzco. It differs from *cecidas* Hew. (102 B a) from Ecuador by larger blue intramedian spots of the forewing and an almost twice as broad light silvery grey instead of blue distal margin of the hindwing.“ — *yurapa* Fruhst. „Peru, Pozzuzo. It differs from *cecidas* Hew. of SEITZ' figure (102 B a) and from *cecidina* by the presence of a bluish-green complementary spot beyond the cell of the forewing, so that this species exhibits the same peculiarity as *P. diotima* from Peru.“

xynites. *P. morona xynites* Fruhst. „Peru, Pozzuzo. Much larger than *morona* Hew. (102 A d) from Bolivia, the green longitudinal band of the forewing narrower, the greyish-blue marginal zone of the hindwing much more extensive.“

plistia. *P. euriclea plistia* Fruhst. „Peru, Pozzuzo. ♂ identical with *euriclea* Hew. var. (Exot. Butt. IV t. 17 f. 90, 91); and different from the figure RÖBER-SEITZ (102 A h) by the green band of the forewing being parted in *plistia*. The greenish border of the hindwing in *plistia* narrower than in *euriclea* from Colombia.“

hilara. *P. hilara* Salv. (102 C c) from Peru (Chanchamayo) is allied to *cabirnia* (102 A d, e). Above it differs from it by the shape of the median band of the forewing and the marginal band of the hindwing, as is to be seen from the figures. Beneath the apex of the forewing is of a pure silvery white, in the black disc there is a blue band broken up into minute spots, and on the hindwing the proximal line almost extends to the proximal margin; between the two lines there are 4 black dots.

clara. *P. clara* sp. n. (102 C d) from Eastern Colombia (Upper Rio Negro, 800 m, A. H. FASSL) resembles *yeba* (102 A h). The upper surface exhibits at the end of the discal cell of the forewing a more strangulated and narrower marginal band. The differences beneath are exhibited in the figure.

marianna. *P. marianna* sp. (?) *nov.* (102 C b) from Western Colombia deviates above from *ilia* (102 A h) by the absence of the submarginal spots of the forewing, a more complete median and a narrower marginal band of the hindwing. The under surface shows the differences to be seen from the figures.

thyoessa. *P. cabirnia thyoessa* Fruhst. „Peru, Chanchamayo, Pozzuzo. An excellent form; the green basal ray of the forewing is not as in *cabirnia* Hew. (102 A d e) from Bolivia, united with the coherent and much broader submarginal band. The light green zone of the hindwing consists of single, proximally pointed spots.

The red zone of the forewing beneath is reduced to a relatively small spot before the apex of the cell — the black area thus covering the whole median space of the forewing.

P. vaninka philiatra Fruhst. „Bolivia, La Paz, Chulumani, Peru, *philiatra*. Chanchamayo. A well distinguished race figured already by RÖBER-SEITZ (102 A g h) and differing from *vaninka* Hew. from Colombia by the broader blue zone on the hindwing above. — *volara* Hew., from Venezuela, is not a species as HEWITSON and RÖBER consider it to be, but surely only a territorial race of *vaninka* Hew. — **gonalia** Fruhst. Venezuela. It is said to be another territorial race excelling *volara* in the size and extent of the bluish-green bands on the forewing and particularly also on the hindwing. In *gonalia* the black dotting on the hindwing beneath is also more prominent. It is not certain whether it is a form of *volara* from the rainy season or from the mountains.“

P. alicia paralicia Fruhst. „Peru. Of a larger habitus and of rounder wing-contours than *alicia* Hew. (comp. *ilia* 102 A h). The bluish-green band of the forewing is much more extensive, the submarginal band of the hindwing, however, scarcely half as broad. Under surface of hindwing with much thinner black lines and extremely small dots. It may be a form from the mountains or the rainy season.“

P. oppelii aisepus Fruhst. „Ecuador. The upper surface differs from *oppelii* Latr. (102 A e f) by an extremely reduced, sometimes only thread-like submarginal band on the hindwing above.“ — **angustifasciata** subsp. n. from Eastern Colombia (Upper Rio Negro, 800 m) has a very narrow marginal band of the hindwing and the yellow basal area of the forewing beneath is very much strangulated.

P. humboldti vestina Fruhst. „Venezuela. ♂ above recognizable by stunted greenish spots and bands on both wings and thereby forming a transition from *humboldti* Guér. (102 A e) to *humboldti tringa* Guér. (102 C b, c) from Peru. Under surface of forewing much more like *tringa* Guér. than Colombian specimens.“ — **exuberans** Fruhst. „♂ differs from *humboldti* Guér. by the carmine discal spot being broadly diffused as in *tringa* Guér. on the forewing beneath. This is the form figured as *humboldti* by RÖBER-SEITZ on t. 102 a. Patria: Colombia.“ — We remark hereto that *humboldti* varies so very much in the size of the red spot on the forewing beneath that it seems not to be justified to denominate the different forms. — **fasciata** subsp. nov. from Bolivia (Rio Songo, 750 m, A. H. FASSL) has a narrow, coherent magnificent band traversing the whole wing, but the equally coloured basal ray does not flow together with it. The red basal area of the forewing beneath is much larger, the black lines of the hindwing beneath are much closer together. The small insect is also smaller and makes the impression of a separate species. — **tenuifasciata** subsp. n. from Peru (Chanchamayo) has a still narrower magnificent band on the forewing above than the preceding, the basal ray is likewise isolated; the red area on the under surface is less developed than in *humboldti*.

P. tringa testacea subsp. n. from Venezuela has a brownish under surface of the hindwing; the same colouring is exhibited on the light parts of the forewing beneath. — **tringa** (p. 497) has been figured on t. 102 C b.

P. guerini aureilimbata subsp. n. from West Colombia (Rio Magdalena) has a narrower and broken-up magnificent band of the forewing and lustrous golden marginal band of the hindwing.

P. dealbata sp. nov. is presumably a subspecies of *compaspe* (103 a), much smaller (about the size of *diotima* 102 B a); beneath very much like *cardases* (102 B b), but the red markings of the forewing are coherent. Patria?

Peris. camelita Hew. (p. 498), *moronina* Rüb. (p. 498), and *jurinei* Guér. (p. 499) we reproduce subsequently.

Genus **Callicore**.

C. consobrina Guér. (102 C a). We have figured specimens corresponding with GUENÉE's description. Western Colombia.

C. gabaza stenotaenia subsp. n. from East Colombia (Upper Rio Negro, 800 m, A. H. FASSL) has a narrower band of the forewing, but a longer and much broader marginal band of the hindwing.

C. seropina sp. n. (?) (102 C a) has been discovered by Mr. A. H. FASSL near Alta Mira on the Rio Xingu, in January. Without a blue reflection; in the ♂ the band of the forewing is much narrower and somewhat shorter, in the ♀ the black spots in the „eights“ of the hindwing beneath are separated.

C. clymena ab. **patriotica** Strd. „A ♂, unfortunately without the habitat being stated, distinguished by a broad green band of the hindwing being midway 2 mm, at the end about 1½ mm broad, and a slightly broader (about 2½ mm) bluish-green band of the forewing, which is more regularly defined and more coherent than in the figure of SEITZ' work (102 B c), thus somewhat like in CRAMER's figure, except that it is excised on the proximal side in area 3 and forming otherwise proximally 2 or 3 small teeth. The marking on the forewing beneath as in SEITZ, that of the hindwing, however, more like in CRAMER's figure, since the black markings are of a deeper black and broader, and besides the light triangular area in an apical direction from the two „eights“ is, like in CRAMER's figure, almost reduced to a punctiform spot; of the two spots of the anterior eight the anterior one is large and circular, whereas the posterior (proximal) spot is almost entirely confluent

with it and about the shape of a comma; of the two white sublimbal bands of the hindwing the distal one is only half as broad as the proximal one. Expanse of wings: 39, length of forewing $22\frac{1}{2}$ mm.“ — The aberration figured 102 B c has been denominated by EMBRIK STRAND: *roeberia*.

bifasciata. **C. bifasciata** Weym. seems to coincide with *phlogaea* (102 B d). The specimen described (also from Colombia) only seems to differ from *phlogaea* by a more intensely green-scaled base of the forewing; it is therefore an aberrative form of *phlogaea*.

ditaeniata. **C. ditaeniata** nom. nov. (= *bifasciata* Fruhst. [nom. praeocc.]). „♂ above most closely allied to *euclides* Latr., the magnificent band of the forewing, however, slightly narrower and proximally with that magnificent azure reflection by which *eluina* Hew. and *eupepla* Godm. are distinguished, although it is not as extensive as in these forms. Hindwing with a submarginal band removed far proximally, of about the extent as we observe in *euclides* Röber (SEITZ t. 102 B e). Distally to this *euclides*-band we find yet another antimarginal stripe of a dull light blue, about of the extent as in *neglecta* (102 B e) Röber in SEITZ. The under surface in almost all the essential marks corresponds with *euclides* (102 B e) RÖBER-SEITZ. Patria: Colombia.“

C. coelinula Guén. (p. 503). FRUHSTORFER declares it to be merely an insignificant local race of *eluina* Hew. (102 B e).

teana. According to FRUHSTORFER, *C. carmen* Guén. (p. 504) is „an absolute synonym of *C. candrena* Godt. (102 B g), whereas the much smaller race from Rio Grande do Sul may be denominated without hesitation (*teana* Fruhst. i. l.).“ This form may be identical with that figured as *candrena* on t. 102 B g. But as *carmen*, according to the material before us, exhibits differences and may be a distinct species, we have subsequently figured it (113 B e).

wernickei. **C. wernickei** Niep. „An intermediary between *gabaza* (102 B f) and *eupepla* (102 B f). Upper surface as in *gabaza*, but black and without a blue reflection. The metallic transverse band of the forewing is green as in *eupepla*, but towards the posterior margin broader and without the ray to the base. The metallic spot of the hindwing as in *eupepla*, but smaller and more lustrous blue. The metallic band at the distal margin is absent, the fringes are hardly noticeably white. Under surface as in *gabaza*; in the forewing the distal part is broader black, the white apical part lighter. The costal margin at the apex more feebly margined with black. The middle black line traversing the apex in its length with a fine white median streak. Hindwing as in *gabaza*, but somewhat lighter. Length of forewing: 23 mm. 1 ♂ from Colombia.“

C. ceryx Hew. (193 f) (p. 502) of which we could not yet obtain a specimen and which we reservedly declared to be an aberration of *euclides* (102 B e), is declared to be a distinct species by DOGNIN, as well as by E. STRAND according to a ♂ from Llanos in Ecuador not quite agreeing with the original figure and description. We therefore reproduce the original figure.

plumbilimbata. **C. gabaza plumbilimbata** subsp. nov. from East Colombia (Upper Rio Negro, 800 m, A. H. FASSL) is distinguished by a leaden-blue marginal band of the hindwing ($1\frac{1}{2}$ to 2 mm). Similar specimens also occur in Venezuela.

Genus **Dynamine**.

motacilla. **D. motacilla** sp. n. (102 C d) from West Colombia is above similar to *pieridoides* (101 A b) and *anubis* (101 A b c), but at the costal margin of the forewing it has a much more lustrous blue colouring; the broad dark distal margin of the hindwing is conspicuous. The hindwing beneath also exhibits the same broad dark margin which, however, is brightened up by the limbal lustrous blue line and by a submarginal whitish band ending anteriorly and posteriorly into a lustrous blue line; the hindwing being otherwise white shows a sub-basal blackish-brown band. The forewing beneath resembles that of *pieridoides*, but it does not exhibit a yellowish, but blackish-brown marking and a much more lustrous blue reflection. According to a ♂.

luisiana. **D. luisiana** Fassl. ♂. „This new *Dynamine* is one of the most splendid surprises of our whole Amazon expedition up till now. The insect forms the intermediary between *gisella* Hew. (101 A i) and *zenobia* Bat. (101 A i). Both wings above predominantly jet-black. In the basal angle of the forewing there is a large spot as in *zenobia*, but of a more light steel-blue colouring; besides the forewing only exhibits a submarginal band being above parallel to the apex proximally indented, 2 mm broad, reaching to the costal margin as well as downward to the posterior margin of the forewing. The hindwing being otherwise quite black is solely decorated by a submarginally placed long reniform spot extending from the anal margin to beyond the distal half of the hindwing. These submarginal bands of both wings are of a dark violet colour (similar to the blue in *gisella*), thus much darker than the more greenish-blue (*zenobia*-like) basal spot of the forewing. The under surface resembles that of *gisella* and of *zenobia*, but it exhibits the orange-brown spot in the basal angle of the forewing which is absent in *zenobia*.“ Patria: Manicoré on the Rio Madeira and Teffé on the Rio Solimoens.

Genus **Chlorippe**.

Chlorippe burmeisteri G. & S. (p. 546, t. 110 B a, ♂). For a ♀ being figured 102 C e I am indebted to the kindness of Mr. P. JÖRGENSEN. It differs to such an extent from the ♀ of *cyane* that the presumption of *burmeisteri* and *cyane* being separate species is thereby more substantiated.

Genus **Agrias**.

(By A. H. FASSL †.)

Since 1916 when the genus was treated upon in Vol. V, p. 566, by the late H. FRUHSTORFER, a considerable number of new forms have been discovered in the districts of the Lower and Middle Amazon River and its affluents having before been little explored entomologically, so that also the systematic division and natural position of many forms can now be arranged according to these results and the much more copious material from much different points of view.

Although our present knowledge of the genus can by no means be regarded as exhaustive, the surprising result is deduced that the Amazon River and the Rio Negro divide the whole enormous range of the genus to the east of the Cordilleras with respect to its forms into two well separated regions; still vast important districts are up to this day entirely unknown with respect to their *Agrias*-races, above all the whole of Venezuela and the enormous plains of the Llanos of East Colombia, as well as the easternmost and central parts of Brazil.

A. claudia. The northern forms, thus the races homed in the Guianas and to the north of the Amazon and Rio Negro differ from all those occurring to the south of the Amazon by their smaller size and more uni-coloured grey under surface, particularly in the band in which the row of eye-spots is situate. Most of the subordinate forms of *claudia* described often occur as aberrations at the same place and time, which fact will be affirmed by every collector of series of *claudia* from well explored habitats, such as the Maroni River in Cayenne, Obidos and Manaos. Both typical *claudia* and all its transitions as far as *amazona* exhibiting the least red colour, as well as those with a proximally notched red bow of the forewing (f. *sahlkei*) are found together at either of the 3 habitats, just like the same forms with a more or less bluish-violet decoration of the fore-and hindwing (*vesta*-forms). Specimens with an intense preapical blue lustre of the forewing have in the meantime been described as **imperialis** Lathy, and an otherwise typical *claudia* (from Manaos and Obidos) the large red spot of the hindwing of which is situate in a still larger bluish-violet spot, thus being the most variegated of all the northern *claudia*-forms, we have denominated: **tuschana** form. nov.

Most interesting are the forms of *claudia* to the west. From Manaos no *Agrias* had hitherto been known; Dr. HAHNEL merely once saw the supposed *sardanapalus* flying, and OTTO MICHAEL obtained an entirely desolate specimen from a settler, which was said to have been taken near Manaos. Among the 40 red *Agrias* I captured near Manaos there is no *sardanapalus*; all of them are forms of *claudia*, of which all the ♂♂ and most of the ♀♀ exhibit rich blue decoration which often entirely removes all the black tints above, whilst the red disc of the hindwing is rather much reduced or entirely absent. Thereby a *claudia*-form is produced near Manaos especially resembling a *sardanapalus*, distinguished from its southern double *sardanapalus* by its remarkably small size and a duller lighter blue of the hindwing being distally bordered by a uniformly broad (almost 1 cm) black edge; the preapical blue spot of the forewing is much more metallic and lustrous sky-blue; the under surface is duller blue but with a more whitish margin than in *sardanapalus*; we denominate the interesting new insect **ninus** form. nov. A form quite similar to it, likewise without a red disc on the hindwing, resembling also *sahlkei*, occurs near Manaos, with a deeply indented red bow on the forewing, of which 4 couples are before us, which are quite constantly coloured and marked and which we denominate *claudia* **biedermanni** form. nov. (t. 113 B a ♂ and ♀) in honour of Mr. ROB. BIEDERMANN, the well-known collector at Winterthur, since the same name having before been applied to a form of *pericles* becomes vacant for reasons to be discussed hereafter. This magnificent new form of *Agrias* in the ♀ already shows distinct attempts of the red band being distally broken up, where it is partly crossed by the black veins.

We now come to the forms occurring to the south of the Amazon River. We do not wish to discuss the question whether *sardanapalus* is justified to be regarded as a distinct species, still we must state the fact that all the forms from the Southern Amazon District that were formerly placed to *claudia* combine certain common marks which are absent in the genuine races of *claudia* from the Northern Amazon District and the Guianas. Beside the larger size, the rounder shape of the wings and the much brighter ochreous-yellow under surface we miss here above all every approach to the aberration *sahlkei* being of such frequent occurrence in the north with the basally angular excision of the red bow of the forewing. The different forms denominated are much more bound to the locality; the discovery of a genuine *sardanapalus* on the Rio Madeira with a large red disc of the hindwing proves the complete gradual transition of the most abundantly red eastern

form *croesus* into the entirely constant form *sardanapalus* of the lowlands of the Central Amazon District. The row of transitional forms from Pará to the Rio Madeira is at present so complete that a separation of *croesus* and its similar forms from the northern *claudia* is no more possible.

I took the typical form *croesus* in very fine and large specimens on the Rio Xingu as well as with *vulcanus*, a somewhat shortened red disc of the hindwing on the Rio Tocantins, from where also the figured form **vulcanus** (113 B a ♂) originates with a blue reflection towards the base and anal part on the hindwing. This is already a transitional form to *A. claudia* (from Rio de Janeiro to Bahia), and still more so is a smaller and more insignificant form from Alcobaca, the first of the rapids of the Tocantins, in which the quite trans-cellular red spot receding towards the apex of the hindwing, encompassing yet the cell, extends in fine red lines along the veins into the disc of the wing: **loki form. nov.** On the Rio Xingu I captured in numbers only the typical form *croesus* Stgr., the legitimate ♂ of which does not exhibit any blue bordering of the red colouring. On the Rio Tapajoz, however, there occurs already a form with a *sardanapalus*-blue anal edging of the red disc on the hindwing and sometimes also blue colour in front of the red bow of the forewing which was placed by STAUDINGER as a ♂ to RIFFAERT's genuine ♀ of *croesus* from Chaves (Island of Marajo). I denominated this form of *croesus* decorated with blue of which I possess beside several ♂♂ also the very rare, likewise anal-wards blue ♀ from the Tapajoz, according to its discoverer: **A. michaeli**.

Cachoeira I, the first of the rapids of the Tapajoz, already has a form with a very small and along the veins dissolved red spot of the hindwing, which is situate in a larger bluish-violet spot (**godmanides Fassl**).

On the Rio Mauès we find a somewhat smaller, very constant local race with carmine magnificent spots hued with violet without a blue bordering, which is more oval in the hindwing and distally less dentate than in *croesus*: **pulcherrima Fassl**.

From the next large tributary of the Amazon, Rio Madeira, finally comes the typical *sardanapalus*; but besides there occur specimens poor in colours, in which the blue in the forewing is entirely absent. My collector H. STRYMPER, however, also succeeded in capturing here 2 genuine ♂♂ of *sardanapalus* which in the midst of the blue disc of the hindwing exhibits yet the large red disc of *croesus*. I denominate the magnificent new form completing an unexpected transition from the east from *croesus* over *michaeli*, from the south from *godmani* to the genuine *sardanapalus*, as **belsazar form. nov.** (113 B a ♂).

Among the greatest number of the ♂♂ of *sardanapalus* lying before me from the Central Amazon lowlands from Madeira to Peru, which are almost quite constantly coloured, I do not possess one specimen with any trace of red in the hindwing; but instead of it the hitherto unknown ♀♀ of the genuine *sardanapalus* are most surprisingly of a quite unexpected variability, to such an extent that often all the analogies of colouring which in the aforementioned eastern forms are bound to certain, far remote localities, occur here in different ♀ forms of *sardanapalus verus* at the same place and time. As a typical ♀ form among the 35 ♀♀ lying before me I denote the form with a uni-coloured greyish-black hindwing without any trace of blue; since it had been observed by collectors already before, but not captured. **rubrimediana** I denominated ♀♀ with red-hued medians of the hindwings; ♀-ab. **purpurea** those in which these lines are condensed to a red discal spot of the hindwing; ♀-ab. **brunhilda** those specimens where the red in the hindwing is replaced by a blue disc, sometimes yet with a blue distal bordering of the red bow of the forewing; thus a retrogression to the colouring of the ♂. Finally I denominated ab. **suprema** (113 B b ♀) an extraordinarily variegated ♀ from Teffe exhibiting in the blue *brunhilda*-spot of the hindwing yet the red spot of the form *purpurea*. Two ♀♀ in which the apex of the forewing is ferruginous which occurs in no other *Agrias*-form above known to me, I described as ♀-ab. **coccinata**.

As to the Andine forms of *sardanapalus*, we may supplementarily add after a consultation with H. LATHY, that his form *hades Lathy* has black hindwings without any blue, so that *decyanea*, which was later on described by NIEPELT (p. 570), is to be cancelled as the synonym of it. Moreover, we must insert yet in FRUHSTORFER's description of the races of *sardanapalus* on p. 570 the form **intermedius FASSL** (from the Eastern Cordilleras of Colombia) which was before described by me; it is the northernmost and most scantily coloured form of *sardanapalus* at any rate, with a dull upper surface as in *Agrias aedon* to which, however, it does by no means form a transition.

A. narcissus does not range as in the previous work of FRUHSTORFER between *phalcidon* and *hewitsonius* but directly after *aedon* to which it is very closely allied and perhaps connected with it by transition in hitherto unexplored districts (Venezuela?). The type occurring to the north of the Amazon invariably shows a red band almost rectangularly touching the costal margin. On the western frontier of its range known hitherto, to the north of Manaos, I discovered to my surprise only ♀♀ with a magnificent ochreous-yellow instead of purple-red band, whilst the ♂♂ were normal; ♀-var. **chrysotaenia** (t. 113 B b).

A still greater surprise on my Amazon exploration was the discovery of a most magnificent, considerably different race of *narcissus* in the southern Amazon District — from the Rivers Xingu, Tapajoz and Mauès — which in contrast with the very constant northern form varies so much at the same place and time that the extreme forms, on their upper surface, do no more resemble in the least the exterior of *narcissus*. All the representatives of this new southern race are considerably distinguished from the type by the red bow of the

forewing never touching the costal margin in a right angle but extending in a flat bow along the costa into the base of the wing, and by the blue colour of the hindwing extending to the distal margin; besides all the southern *narcissus* are much larger, and often the cornflower-blue also covers the red areas which produces a coloristic effect excelling even that of the most variegated *sardanapalus*; all the following coloristic varieties (except the yellow form) are common to both sexes; the under surface of all the forms is marked and coloured as the typical *narcissus*. — The form **tapajonus** Fassl (113 B b ♀) is the southern race being the most closely allied to the type. In the form **dubiosa** (113 B b ♂) — which I took to be a form of *claudia* according to the quite old specimen taken first on the Tapajoz — the red bow is downwards widened as far as the submedian. A couple of *dubiosa* from the Rio Xingu besides exhibits a red pupil in the hindwing in the shape of a carmine transcellular spot. The form **porphyronis** Fassl (113 B c) represents the transition for which I had long been searching to the most variegated form *narcissus illustrissimus* Fassl (113 B c ♂) which almost entirely resembles above a *claudia michaeli*, whilst another specimen resembles *sardanapalus belsazar*. On the Rio Maurès I finally captured beside the typical *narcissus tapajonus*-♀ also a magnificent aberration with a golden yellow band of the forewing — ab. **icterica** Fassl being in the colouring analogous to the northern form *chrysotaenia icterica*. from which, however, the Maurès-insect differs considerably by exhibiting the characteristics of the southern races, the flat bow of the forewing and the blue colour being spread across the whole surface of the hindwing.

Of the forms of *A. amydon* the following are to be ranged in the species *pericles* as they have in common with it a rust-coloured yellow or red body, a similar base of the hindwing and the inclination to a blue preapical embedment in the forewing which blue colouring is in variegated specimens like the blue of the hindwing distally besides bordered with green festoons. Thereby the *pericles*-group differs from the purely Andine forms of *amydon* in which these marks are always absent; the races of *pericles* are besides almost invariably much smaller, the very long apical strigae of the forewing always show through above also in the ♂♂ as 2 or 3 very large yellowish-white dots.

In case my present expedition *) should be successfully completed, probably all the non-Andine forms having hitherto been combined with *amydon* will have to be rearranged in *pericles* by the discovery of the very rare variegated transitions to the latter species, so that the eastern foot of the Cordilleras would then form the natural frontier between the range of *A. amydon* and *pericles*, as is also the case with many other closely allied species of lepidoptera, e. g. *Papilio harmodius* and *ariarathes* the range of which is divided by the same line.

It has hitherto been proved for certain that the northern forms *A. aurantiaca* and *trajanus* belong to *pericles*, the former representing merely a coloristic variety of the latter, since both forms fly at the same time and place near Obidos as well as to the north of Manaos. Beside a ♂ of *trajanus* from Obidos with a faint dark blue preapical reflection of the forewing, I possess a ♂ of *aurantiaca* from Manaos with a blue embedment at the same place but also already a dark blue disc of the hindwing. Still more than these specimens do, the figured form **praxiteles** (113 B c ♂) proves the relationship to *pericles*, representing nothing else but a ♂ of *trajanus*, in which the preapical spot of the forewing already exhibits a tendency to a green bordering as in *pericles*; I took the insect near Manaos.

The typical *trajanus* shows the same orange-red colour as the figured *praxiteles*. By FRUHSTORFER speaking in his description of *trajanus* on p. 573 of a purple spot of the forewing and dark red powdering on the hindwing it happened that I described *trajanus* once more as *pericles biedermaani* which name has now to be placed as synonymous to *trajanus*, since also Mr. LATHY (Paris) has indisputably identified the types of *trajanus* in an English collection. The white wedge-shaped streaks of the hindwing on which FRUHSTORFER in his diagnose lays such great stress, are moreover sometimes absent in specimens from Obidos, almost invariably in those from Manaos.

Of the *pericles*-forms from the South Amazon the Rio Tapajoz unites the most shades at the same place. Here we meet with variegated red-banded specimens allied to the typical *pericles* of the Solimoes, and in which the distal bordering of the blue areas exhibits bright green festoons, as well as all the transitions to quite scantily coloured specimens showing but minute traces of blue and green; the very same gradation is exhibited by the cell-banded forms there (*xanthippus* Stgr.), in one of the specimens I captured there we even notice no trace whatever of blue and green, and this plain blackish-yellow specimen recalling the ♀-colouring is at any rate and presumably the most poorly coloured of all the ♂♂ of *Agrias*, which I denominate *pericles* ♂ ab. **tristis**.

Whereas formerly only a ♀-form of *pericles* being similarly coloured like this was known, I succeeded in taking besides several ♀♀ being alike, in which the black preapical zone of the forewing is profusely strewn with golden green scales; sometimes the veins traversing this green area are besides hued dark blue — ♀ ab. **chlorotaenia** Fassl. Still more singular is a ♀ which I at first mistook for *phalcidon-anaxagoras*, before I knew the legitimate ♀ of the latter, which, however, certainly also only represents a variegated ♀ form of *pericles*: **mirabilis** Fassl (113 B d ♀); it exhibits a subapical embedment similar to *chlorotaenia*, though of a blue colour in which on the contrary the veins are hued green. In the hindwing the orange-powdered base is followed

*) The author of these lines, A. H. FASSL, has unfortunately died in the meantime at Manaos.

mirabilis.

by a black discal area, then comes a broad, dull dark blue submarginal border distally defined by a fine equally broad green silvery line; the most peculiar feature, however, in this insect is the strangely shortened yellow bow of the forewing, almost looking like a transition to the basal spot of *anaxagoras-hewitsonius*.

mauensis. The Rio Mauès yielded a much more constant race of *pericles* — **mauensis** Fassl — in which there is no green festoon at all, the fore-and hindwing being profusely violettish-blue; the magnificent bow of the forewing may be purple-red, orange or yellow. The ♀ is without decorations like the normal one of the Tapajoz-forms, but it invariably has a dark metallic green reflection in the hindwing at the place where the strigae are in the northern forms. Only a single ♀ from Mauès is more variegated with a similar though much duller blue decoration than the ♂ and a light orange-red band; I denominated it ♀ ab. **coronata**.

coronata. The Rio Madeira has by no means supplied a transition from *mauensis* to the typical *pericles*, but a very peculiar lepidopteron which one might almost take to be the ♂ of *pericles mirabilis*-♀; it looks above and beneath very much like the figured *hewitsonius journerae*-♂ from the same habitat, and has likewise an orange basal spot of the forewing not extending beyond the cell; then follows a dark blue zone ending in a narrow green border at the distal margin; just as dark blue with a fine green bordering which, however, is more intense analwards, are the hindwings. Particularly the latter circumstance, besides the remarkably long apical strigae beneath showing through towards the apex of the forewing as 3 purely white dots, the rust-coloured yellow base of the hindwing above and no less the small size of the insect are certain proofs that it belongs to *pericles*. I name this new form **ahasverus**; it has been discovered by my collector A. LUIZ STRYMPLE, and it is the only representative of *pericles* known hitherto from Madeira. Its great resemblance to a form of *hewitsonius* flying at the same habitat is by no means a sporadic occurrence in the variations of well separated insects of the same genus; I only mention as similar examples: *Heliconius melpomene* and *vesta viculata* near Santarem, *Morpho-hecuba* and *metellus* near Obidos, *Morpho cisseis* and *perseus crameri* near Parintins etc.

gloriosa. That also *A. ferdinandi* Fruhst. and its recently described variegated form **gloriosa** Lathy — with a profuse blue preapical embedment in the forewing — are nothing else but southern forms of *A. pericles* resp. of its Matto Grosso forms, is easily to be made out from the aforementioned common marks of the races of *pericles*. But also *tryphon* Fruhst. and *amydonius* Stgr., of which we have at present too little material, seem to belong to *pericles*.

On p. 576 we have to insert in *A. mapiri* in the 8th line from above after the word „*Agrias*“ the word „*pericles*“.

phalcidon. **A. phalcidon**. I must premise that the range of this species as well as of the close allies and of the *hewitsonius* being connected by transitions, is probably only confined to the Southern Amazon District in spite of some contrarious statements. Both myself and my collectors were for a long time active at different places to the north of the Amazon and Rio Negro without ever beholding a blue *Agrias*. An entirely typical ♂ in the Paris Museum, which merely exhibits a somewhat greyer scent-pencil and is labelled as „Obidos“, I most positively consider not to originate from there.

xinguensis. Two geographical forms are also known from the east of Itaituba on the Tapajoz, both of which invariably exhibit as the principal mark red basal marking on the hindwing beneath. **xinguensis** Fassl (102 C f), which is besides somewhat more bluish steel-green, exhibiting smaller ocelli beneath and mostly a large metallic lustrous steel-green spot in the distal half of the forewing beneath, was discovered by me on the Rio Xingu, whereas **rubrobasalis** Fassl forming the transition to the typical form occurs on the northern frontier of the Amazon District from the mouth of the Xingu upwards as far as Santarem and from here the right bank of the Tapajoz upwards as far as Monte Christo.

rubrobasalis. In the blue *phalcidon*-form *paulus*, on p. 576, we must remark that the specimen taken by Dr. HAHNEL near Parintins is not a ♀ but a ♂. I took the very singular ♀ probably belonging to *paulus* on the Tapajoz in a single specimen (113 B d ♀).

The type of *phalcidon anaxagoras*, according to its discoverer H. OTTO MICHAEL who also furnished us with a drawing, by no means exhibits almost entirely black hindwings as FRUHSTORFER writes on p. 576, but analogous to my two more ♂♂ taken near Itaituba it is like a normal *phalcidon*-♂ also in the hindwing profusely decorated with blue and green. The ♀ of *anaxagoras* (113 B d ♀) having hitherto been unknown, which I took on the Tapajoz in 2 rather similar specimens, is very much like the ♀ of *A. hewitsonius* (113 B d).

We likewise figure here the ♀ of the genuine *A. hewitsonius* (113 B d) from Teffé, which was hitherto unknown; all the specimens I captured are entirely constant. The figure of *hewitsonius* ♂ beneath on t. 114 c is of a somewhat too bright green colour; besides the ♂ above mostly exhibits a much more extensive green marginal line almost invariably reaching the posterior margin of the forewing and being in some ♂♂ even rudimentarily continued in the apex of the hindwing.

Although my prior presumption that *A. phalcidon* and *hewitsonius* are merely local races of the same species had been very strongly opposed, the discovery of an extremely magnificent intermediate form on the Rio Madeira, *A. fournierae* Fassl (103 C f ♂) must be considered as a confirmation of my opinion. The blue colour above is of a still much more magnificent and lighter metallic lustre than in the genuine *hewitsonius*-♂; a narrow, green border only occurs in the figured specimen; in 4 other ♂♂ of *fournierae* it is entirely absent; a rather broad black distal margin likewise recalls *hewitsonius*. Beneath there is no trace whatever of a green colouring or of a basal bordering; instead of it the yellow colour is spread across the whole light tints of the under surface, which is not the case in any other of the *phalcidon*- and *hewitsonius*-races known hitherto. *A. fournierae* has 2 different ♀ forms; the typical most magnificent form on both wings resembles the ♂; it is by one third larger, the blue is lighter, metallic light violet and without any trace of green. The other very different ♀ form — ♀ ab. **calliste** — is somewhat smaller and less variegated, it only has a duller blue before the orange spot, turning soft steel-green towards the apex and costa; the hindwing likewise only shows a dull discal blue decoration.

At the same time and place I also took 2 quite constantly aberrant ♂♂ of *fournierae* in which the orange basal spot of the forewing is reduced to a narrow longitudinal stripe dissolving towards the lower cell-margin into fine yellow atoms in the blue ground-colour: form. **viola** Fassl (113 B).

Whilst *A. fournierae* looks like an enlarged form of *Callithea batesi aimeana* from the same habitat, the form *viola* involuntarily reminds us of the magnificent *Catagramma excelsior michaeli* Stgr. occurring at the same place.

Although we may be in doubt whether the new magnificent insect is to be placed to *phalcidon* or *hewitsonius*, probably already the nearest future will yield some more interesting intermediate forms connecting *phalcidon* with *hewitsonius* also with respect to their very different under surfaces.

Genus **Siderone**.

Sider. marthesia Cr. (p. 577) has been found again by Mr. A. H. FASSL near Itaituba on the Tapa-joz; we had 1 ♀ from FASSL's collection figured (102 C f); the under surface corresponds to that of *confluens* (116 a), but the forewing shows a yellow ground-colour.

Genus **Anaea**.

A. suprema Schs. (= *zikani* Rbl.) (102 C e) is one of the most remarkable and most magnificent species of this genus and has only recently discovered by Mr. J. F. ZIKAN near Fazenda dos Campos near Passa Quatro in the southern Minas Geraes at an altitude of 1600 m, the small insect in the male has about the shape and size of *falcata* (120 D e), but the body is less robust; the upper surface is bluish-black with a slight reflection and has a broad, almost golden red costal-marginal band, but the costal margin itself is bluish-black beginning from the middle of the discal cell, the distal margin of the forewing is, like the apex of the wing, somewhat broader and reddish; the hindwing has a somewhat paler red distal-marginal band of about 3 mm width. The under surface resembles that of *tyrianthina* (118 e). The ♀ forewing above shows a ground-colour similar to that of the ♀ of *Chrysophanus virgaureae* (Vol. I, t. 76 a), the costal margin is black, in the centre a broad black band growing broader in front towards the rear and with unequal margins, being particularly distally sharply dentate in the areas of the wing; in this black band there are three large spots of the ground-colour; the hindwing is black with large, yellow, coherent spots and with an antemedian row of equally coloured, sharply defined spots. The under surface shows a more distinct black marking than in the ♂, at the end of the discal cell of the forewing there is a black spot. As to the early stages, F. ZIKAN has published the following account *): „The globular egg, being somewhat flattened at its upper pole, is feebly corroded, of a lustrous greenish-white, and has a diameter of scarcely 1 mm. It is singly deposited on the underside of leaves of a tree-like species of *Croton* (according to Dr. RECHINGER *Croton gossypifolium* H. R. K., called „*Sange di Drago*“ by the natives), mostly at a considerable height. The total amount of eggs of a ♀ is about 200. The small larva leaves the eggs 11 days after the ovipositing. It is then 3 mm long, dingy green, with a dark brown, black spotted head and one subdorsal and one lateral row each of scanty bristles. After about 2 weeks the first casting of the skin takes place. After this the small larva is about 10 mm long, dingy green, with the characteristic, quadrangular, red-brown spots (of the *Anaea*-larva, of which the saddle-spot is the most conspicuous. Below the stigmata the larva is coloured yellowish. Its skin is densely covered with low, yellow tubercles with short black bristles, the head showing a crown of spines. After the second skinning the ground-colour of the larva has turned cinnamon-red. The red-brown, interrupted dorsal line and the lateral spots of the same colour already correspond with the adult larva, and so do the spining and colour of the head, whereas the integument (the skin) exhibits the former state.

*) Zeitschr. Oesterr. Ent. V. Wien, Jahrg. 1921, No. 1 and 2.

After the third skinning the larva shows the same exterior. The adult larva (after the fourth skinning) is 50 to 55 mm long and exhibits a pink ground-colour turning lilac on the dorsum. The first four segments are slightly covered with spine-like, small yellow tubercles on a greenish ground, arranged in longitudinal rows, whereas on the other segments, particularly on the sides, they are but scantily arranged, so that the ground-colour is visible there in rectangular lustrous spots. The head exhibits a three-coloured demi-crown of dingy green spines with yellow tips, the two middle ones which are the largest and singly forked. The dark frons with two pink lateral stripes. Before the pupation the larva turns green. The young larva begins to feed on the apex of the leaf which it prolongs by a web mixed with clods of dirt, which it only leaves during the first two stages of skinning in order to feed. After the second skinning the larva makes itself a bag by rolling up the edge of the leaf which is also on the inside clad with a web. The larva in day-time sits in the bag with its head turned towards the opening and mostly only leaves it at night for feeding. The third and fourth skinning takes place in the bag which is several times made larger on a new leaf. In spite of the bag the larvae are sometimes infested with parasites (*Tachinae*, *Microgaster*). The worst enemies, however, are birds which pick open the sides of the bags. The pupation takes place in a leaf being joined together, but mostly not on the food-plant. The immovable pupa is short and compact, 18 mm long, 13 mm broad, green, with a silvery white (sometimes orange-reddish) longitudinal line on both sides of the dorsal carina and such lateral oblique stripes as far as the proximal margins of the wings. The ventral side of the pupa is uni-coloured green. The discoloration of the pupa takes place 6 to 8 days before the imago is yielded and shortly before it already shows the sex in the transparent marking of the wings. The pupal stage of the summer generation lasts for 30 days (November to December), that of the spring generation hibernating as a pupa for 60 to 94 days (May to July-August, exceptionally to September). The generation of the hibernating pupa needs, in order to develop well, dampness and cold temperature (sometimes as much as 5 degrees below zero)."

A. xenocrates Ww. ♀. „The ♀ is but slightly larger than the ♂ of the species (120 D d) and of rather the same shape of wings, thus also without tails. All the steel-green spots of the ♂ are in the ♀ golden ochreous, whereby the female assumes quite a different appearance. The finely watered under surface does not exhibit, as in the ♂, a slate-coloured greyish-blue, but ochreous-brown ground-colour. According to several rather similar ♂♂ from Teffé (Ega) and to the north of Manaos.“ (FASSEL.)

demaculata.

A. xenocrates demaculata subsp. nov. was discovered by FASSEL in August in Manicoré (Amazon River). It is smaller than *xenocrates typica* (120 D d), the blue spots of the forewing are reduced to 4 being scarcely half the size of those in *xenocrates*, the marginal band of the hindwing consists of small isolated spots, and the ground-colour beneath is lighter.

A. porphyrio Bat. (119 a). We had subsequently also the ♀ figured (102 C e). This species does not only occur near Pará (on p. 585 misprinted into „Peru“), but probably also on the whole Lower Amazon River; it flies from July to September.

Of *A. eribotes* F. (p. 585) we figure a ♀ (102 C d) having been taken by Mr. A. H. FASSEL near Manaos. Perhaps it forms with *porphyrio* (119 a) and *testacea* (119 a) a single species occurring in various shapes.

polyxena.

A. polyxo polyxena subsp. nov., captured by A. H. FASSEL in some ♂♂ near Manicoré on the Rio Madeira in August, is remarkably smaller than typical *polyxo* (120 D a b), the markings are not verdigris, but blue with a purple reflection and the marginal band of the hindwing is not sharply defined, but it gradually turns proximad, and only extends from the proximal angle to the anterior radial.

anceps.

A. anceps sp. nov.? (102 C d e). Mr. A. H. FASSEL, in January 1922, captured some ♀♀ of it near Manaos (Lower Amazon) and presumes them to belong to a species the ♂ of which has not yet become known. But it is neither impossible that they belong to a species from the *glauce*-group, may-be *felderi* (119 d), the under surface of which is similar to that of *anceps*.

A. basilis Cr. (p. 589, 193 e). Of this species Mr. A. H. FASSEL has discovered the ♀ near Mauès (102 C f as *basalis*). The under surface is grey with blackish and whitish speckles, two white, black-pupilled spots near the base of the tail-appendage, a black median stripe across both wings, which, however, neither reaches to the costal margin of the forewing nor to the proximal margin of the hindwing, and black spots at the costal margin of the forewing, particularly a large spot at the end of the discal cell.

caucana.

A. rosae caucana J. & T. from the Cauca Valley (West Colombia). „Forewing with rather small subapical spots, as they are reduced towards the base, and the bands correspondingly indistinct. Fringes of a bright brown and slightly dusted with the same colour. Hindwing with traces of a bluish costal spot. Distal margin of a bright brown, which colour gradually disappears in the ground-colour. Under surface with reduced white markings and the spot in cell 7 of the hindwing fainter.“ — Synonymous with *laura* (p. 590, t. 120 A d)?

discophora.

A. discophora sp. nov. (102 C e) from Peru (Pozuzo) is remarkable by a large, very scantily scaled and therefore semi-transparent spot of the forewing occupying almost the whole distal half and only leaving free

the proximal angle and a stripe at the proximal margin; it might be taken as a scent-scale spot, if such formations would not be uncommon in this genus. The under surface resembles that of *plantes* (120 A c), but the ground-colour is darker and the light band of the forewing is complete and extends into the apex of the wing, expanding near the proximal angle into a light triangle.

Lycaenidae.

The „Check-List“ having in the meantime been published by WM. BARNES and MC. DUNNOUGH, as well as personal reports by Mr. W. T. M. FORBES, Ithaca, N. Y., to whom we are greatly indebted, necessitates some alterations in the elaboration of the North American *Lycaenidae*.

Th. publica Rôb. is very much like the ♀ of *paphia*, but it has narrower wings; the black distal margin of the forewing is narrower and turns proximad on the veins in a dentate shape; the tail-appendage on the 1st median vein is broader and at the borders broadly covered with green lustrous scales. Beneath on the forewing the green marginal scaling is reduced, the black median band of the hindwing is narrower, irregularly defined, in the middle broader than in front, not sharply angled, but softly bent, the distal parallel band is absent, but instead there are two black submarginal cucullate spots, behind them yellowish-greenish dusting. Abdomen beneath loam-coloured yellow. According to 1 ♀ from West Colombia (Rio Magdalena). — This form is to be inserted on p. 746 behind *paphia*. *publica*.

Th. polios Cook & Wts. (p. 761) is not a synonym to *mossi*. The latter species is uniformly chocolate-brown above, whereas *polios* is browner towards the margin on the hindwing. On the under surface the distal margin of the hindwing of *mossi* is contrastingly red-brown with six more or less distinctly visible, small internerval spots, whereas the forewing has no marginal part contrasting by a different colour. In *polios* the hindwing shows a broad light grey distal-marginal part, lighter than in *irus*, and the forewing exhibits a whitish, 1 mm broad margin before the fringes. *polios* originates from Maine and Colorado, *mossi* from the western half of the States and from Pennsylvania.

Th. dumetorum Bsd. (p. 763). The typical form in the ♂ exhibits a blackish grey upper surface, occasionally tinted with a faint brownish red, in the ♀ more distinct. Beneath the sexes are similar, with rows of white at least on the hindwing, in about 90 percent on the forewings and hindwings. Range: California. — f. **perplexa** Barnes and Benjamin, a geographical race from San Diego (California), differs by the entire or almost entire absence of the small white spots beneath; the coppery grey area at the proximal margin of the forewing almost extends to the costal margin and parts a green basal area from the green apical area; the fringes are not quite purely white. It was usually mixed up with the Colorado-race of *apama* and the *sheridanii*-race from Utah. *perplexa*.

C. affinis (p. 763) in both sexes shows a constant red-brown ground-colour above; the forewing exhibits beneath at the proximal margin only a slight darker shade. Fringes distally purely white.

C. apama (p. 763) is in the typical race from Arizona above grey, often with an intense coppery tint, in the ♀ in the disc coppery red-brown, with fine black veins. The under surface in the colour resembles the race *perplexa* of *dumetorum*, the white markings are still more prominent and usually bordered with a red-brown band. The white band of the hindwing consists of white, crescentiform confluent spots, in the centre very much distally angled, proximally bordered with black, behind it with a red-brown band. Fringes quite dark, at the anal angle of the hindwing white. — f. **homoperplexa** Barnes and Benjamin is the race from Colorado. Above the ♂♂ are redder than any other species or race except *affinis* from which it is easily discernible by the coppery or red-brown spot on the forewing beneath extending from the proximal margin to the costal margin. Beneath the white markings bordered with black and brown are reduced to single small spots, and may occasionally disappear altogether. *homoperplexa*.

C. sheridanii in the typical form shows dark grey wings above and is beneath darker green than the other species; both wings are beneath crossed by bands of small white punctiform spots, on the forewing almost, on the hindwing entirely confluent, so that they are here no more discernible as single dots, proximally bordered by a distinct black line. Fringes purely white. Denver (Colorado). — f. **neoperplexa** Barnes and Benjamin is the race from Utah which is above lighter grey and does not exhibit any purely white fringes. Beneath the white dots are reduced, on the forewing occasionally disappearing altogether, on the hindwing forming a thin line. *neoperplexa*.

C. xami (= *blenina*) (p. 772), as well as *rhodope*, *loki*, *spinctorum*, *johnsoni*, *castalis*, *siva* and *nelsoni* ought to be placed with *damon* (p. 798) together into the subordinate genus *Mitoura*: *siva* Edw. must be eliminated as a synonym to *xami*, the type is very closely allied to *nelsonii* or its form *muirii*, to which it may belong as a synonym according to Barnes and Benjamin. — *castalis* belongs to *damon* and has the priority of its form *discoidalis* Skinn. (p. 798). We add another form to it: r. **patersonia** Brehme, a seasonal form, being dark sooty brown ♀♀. *patersonia*.

Habrodais (not *Habrodias*) *grunus* Bsd. (p. 773) is no real *Theclina*; it has a forked apical vein and enlarged anterior tarsi like some allies of the African *Lycaena*.

Crysalus Edw. (p. 773) belongs into the genus *Zephyrus*.

Th. lorata Grt. & Rob. (p. 773) is an artificial produce; the diagnose is not correct; it is a typical specimen of *calanus* on the under surface of the wings of which a black subbasal line has been painted.

Th. ontario Edw. (p. 773) is the northern race of *autolytus* and to be ranged there (p. 774, line 1 from above). It is a small form without the small orange marginal spots. Very rare, also from New York and Massachusetts.

Th. aurette Bsd. (p. 774). We must insert here as synonym *tacita* Edw. (p. 772, line 10 from below) and *tetra* Behr (p. 774). — *spadix* Edw. (p. 773) is only a southern race of *aurette* without the small orange anal spots; the ♀ is above broadly rust-coloured yellow in the disc. The under surface is more ochreous-yellowish with extinct markings.

Th. laeta Edw. (p. 783) from eastern habitats of North America is beneath greenish-grey, similar to *quaderna* (155 i) from Mexico.

According to clause 36 of the international nomenclatural rules, the species denominated *damon* on *smilacis*, p. 798 would have to be called *gryneus* Hbn., *damon* becoming synonymous. — f. **smilacis** Bsd. & Lec., mentioned as a synonym of this on p. 798, is the eastern form with a dark brown, almost monotonous upper surface (sec. Barnes and BENJAMIN), but according to the kind information by Mr. FORBES it is the long-tailed southern race. Beside the races *castalis* Edw. (= *discoidalis* Skinn.) and f. *patersonia* Brehme *brehmei*, (p. 1043) having been already mentioned before, we must yet insert: f. **brehmei** Barnes & Benjamin as the Texas-race of the form *castalis* Edw. with its under surface, but like *smilacis* with a darker upper surface.

Th. titus (p. 811). Add to it: f. **immaculosus** Comst. with an unspotted under surface.

Ch. del Sud Wright (p. 812) becomes synonymous to *hermes* Edw.

Th. mariposa Reak. (p. 813), according to BARNES and MC. DUNNOUGH is to be provided with the synonym *zeroë* Bsd., *nivalis* Bsd., however, with the synonym *ianthe* Edw.

The form *florus* Edw. (p. 813) belongs to *helioides*, not to *dorcas*.

Th. fuliginosa Edw. (p. 814) is no *Lycaenid* but a *Theclina* beside *Callipsyche behri* (p. 774).

Lycaena heteronea Bsd. (p. 814) to which *clara* Edw. belongs as a form is no *Lycaena*, but it belongs to the *Chrysophanus*-species beside *rubidus* (p. 813) with which it is closely allied in spite of the blue ♂!

L. icarioides Bsd. (p. 815). According to the latest investigations, the synonymy and forms are quite differently arranged: ♀ = *maricopa* Reak.; synonyma of it are: (= *phileros* Bsd., *fulla* Edw. [of p. 814], ? *mintha* Edw.). The typical form flies in the Californian mountains. The forms are: ab. *daedalus* Behr (144 b, p. 815), f. *helios* Edw., f. *evius* Bsd. from South California, f. *ardea* Edw. from Nevada, Utah and Colorado, f. *lycea* Edw. (= *rapahoe* Reak.) of p. 814 from the Western Rocky Mountains and finally f. *pembina* Edw. from Manitoba and the northern Rocky Mountains to the south as far as Wyoming and Montana.

L. hilda Grimm. is to be placed as a synonym to *achaja* Behr which comes as a form to *saepiolus* Bsd. (line 19 from above), not as a synonym.

L. kodiak Edw. is to be placed as a form to *scudderii* Edw. (p. 817). *mela* Streck. is to be eliminated and becomes a synonym to *cyna* Edw. (p. 819).

L. pardalis Behr (= *erymus* Bsd.) (p. 815) has nothing to do with *icarioides* Bsd., but belongs into a quite different group otherwise not at all represented in America, to *Lycaena* in its proper sense with *arion* as the most closely allied species. Above entirely like *icarioides*, beneath on a deep brown ground with intense black spots with fine whitish rings. California. — The third synonym mentioned in *icarioides* (p. 815), *mintha* Edw., most probably belongs to *ardea* Edw. (a form of *icarioides*).

L. antiacis Bsd. (p. 816) belongs as a form to *xerxes* (p. 815), as well as *meritula* Edw., whereas *behrii* Edw. belongs to *lygdamas* Dbld. to which also *couperii* Grote is to be placed.

L. sagittigera Fldr. becomes a synonym; insert as the correct name: *piasus* Bsd. of p. 818.

L. speciosa Edw. is not a *Phaedrotes*, but it comes to *Philotes* beside *sonorensis* Fldr.

L. podarce Fldr. and *rustica* Edw. (p. 816) are to be placed as forms to *aquilo* Bsd. (p. 816).

L. enoptes Bsd. (p. 816). With respect to this group and *battoides* the studies of BARNES and MC. DUNNOUGH have resulted in entirely different opinions which we state in the following. Above all the species belong into the 5th subordinate genus: *Philotes*, and not to *Rusticus*. *enoptes* and *battoides* have quite different genitals, whereas *glaucon* is not to be separated from *battoides*. Those being especially interested in these difficult questions may compare: Contr. Nat. Hist. Lep. N. Amer. Vol. III, Nr. 2, p. 116; Vol. III, Nr. 4, p. 213 seq., and Vol. IV, Nr. 2, p. 77 seq.

The arrangement of the forms is accordingly as follows:

P. battoides Behr is an alpine form from altitudes of 7 to 11 000 ft. and characterized by intense quadrangular black spots beneath on a very light whitish ground which is very much strewn with black, with a broad black marginal line on both wings and a broad, red submarginal band of the hindwing; the fringes of both wings distinctly speckled. Above the ♂ is very variable in the development of the orange-red spots on the hindwings, some specimens are without, others with a distinct band as beneath. A much smaller race: f. **bernardino** B. & McD. of about 20 mm expanse flies on low mountains in California (S. Bernardino Mts. and S. Diego) with a decidedly lighter ground-colour and less interne black markings beneath, particularly on the hindwings which are hardly strewn with black. — Another race: f. **oregonensis** B. & McD. originates from Oregon and is characterized by a much broader black border on both wings above in the ♂, which may occasionally cover the whole half of the hindwing; beneath the space between the postmedian row of spots and the orange marginal band is in both sexes larger than in other forms, the spots are less quadrangular, the ground shows a slight greenish tint. — A third form, the under surface of which forms the transition to *enoptes*, is f. **intermedia** B. & McD. occurring in the valleys of the North and Central Californian mountains. The spots of the hindwing beneath are much smaller, the orange submarginal band divided into small lunae, the dark marginal line as fine as a hair. Above in the ♂♂ the black border is moderately broad, the fringes of the hindwings are white, not speckled, at the anal angle of the hindwing slight orange spotting. The ♀♀ have a much broader orange band than the very similar ones of *enoptes*. In the Rocky Mountains of Colorado and Utah there flies a similar race: f. **centralis** B. & McD. with a broader dark border of the wings above and intense orange spotting at the anal angle of the hindwing in the ♂♂; beneath the ground is browner, the spots are larger, distinctly ringed white, the orange band more coherent, at the anal angle of the forewing dark shading. According to the very latest investigations and after having discovered the type of *glaucan* Edw. the latter has now proved also to belong to *battoides* and not, as was originally supposed, to *enoptes*; the genitals entirely agree with *battoides*; in the exterior the type is very much like *centralis* and *intermedia* by the intense black basal band of the fringes beneath.

The *enoptes*-form having hitherto been regarded as *glaucan* had therefore to be renamed: **ancilla** B. & McD. which thus entirely resembles *glaucan* Edw. above; beneath the scaling is somewhat rougher, and the black marginal line of the hindwing is stronger; the ♂♂ exhibit above at the anal angle of the hindwing but traces of orange scaling. From *enoptes* the form differs by the coherent orange band on the hindwing beneath which in *enoptes* is invariably divided into spots; besides the black spots are more prominent. Utah and Colorado. Insert after it:

Ph. spaldingi B. & McD. very much resembles *ancilla* above, but the anal angle of the ♂ hindwing is very intensely spotted orange, the under surface is lighter, the black spots of the hindwing much smaller, whereas on the contrary those of the forewing remain large and intense; the forewing shows a broad orange submarginal band not reaching to the costal margin and growing narrower towards it; on the hindwing this band is divided into small moon-spots by the veins and proximally very faintly, towards the costal margin at most, defined by blackish. The ♀ is dark brown, the orange marginal band of the hindwing is continued on half the forewing. The genital organs are very different from those of *enoptes*. Apparently rare and confined to but few mountainous districts of Utah.

Ph. rita B. & McD. is likewise closely allied to *enoptes*, but distinguished by its whiter ground-colour beneath with a broader orange band; the black spots are much stronger and the blue of the upper surface of a more violet tint. The genital organ is very different, but still most similar to *glaucan* from which it differs by a much longer terminal spine on the valves. Expanse of wings: 23 mm. South Arizona.

L. minnehaha Scddr. (p. 817) is not to be placed as a synonym of *shasta* Edw. (p. 817); it represents a good form different by much narrower black borders without orange, but with a white marginal line and distinct black marginal spots on the hindwing above. At greater altitudes in Colorado.

To *scudderii* Edw. (p. 817) add *aster* Edw. (p. 144 g, h) as the race from New Foundland. Two more forms of this species are: *annetta* Mead. (144 g) line 14 from below and *kodiak* p. 815 (144 c).

The arrangement of forms of *acmon* Dbld. & Hew. is to be altered as follows: *acmon* remains with the synonym *antaegon* Bsd. As the only form we add to it: f. *cottlei* Grinn. about which, however, we were at present not able to ascertain anything. — *monticola* Clem., *chlorina* Skinn., *emigdionis* Grinn. (= *melimona* Wright), *neurona* Skinn. are all said to represent good species. We have to add hereto as another species: *lupini* Bsd. about which we can at present not say anything and which is therefore to be eliminated as a synonym of *shasta* Edw.

Genus **Lycacenopsis** Fldr.

This name is to replace *Cyaniris* on p. 818. The species is not called *ladon*, but *pseudargiolus* Bsd., with *violacea* as synonym.

Genus **Everes**.

Add to *E. comyntas* Godt. (p. 818, t. 144 i) as synonym: (= *sissona* Wright), and as its form: f. *herrii* Grin. which belongs hereto, not to *amytula*.

Genus **Hemiargus**.

Add to *H. gyas* Edw. (p. 819) as synonyma: (= *astragalus* Wr., *florencia* Clem.), and f. *zachaeina* Btlr. & Drc. as the form from South Texas, Mexico and more to the south.

Add to *H. cyna* Edw. (p. 819) as synonym: (= *mela* Streck.).

H. hanno Stoll (p. 819). Of the synonyma mentioned here *hamo* Luc. and *artenides* Bsd. are to be eliminated, both presumably belonging to a West Indian species which is at present not to be identified for certain and which is mentioned by HÜBNER as *hanno* (Exot. Schmett. I, t. 98), though it has nothing to do with *hanno* Stoll and much rather resembles *gyas* Edw.

Hesperiidae.

The most difficult chapter of the diurnal lepidoptera has in the meantime gone through many far-reaching alterations which makes our whole work appear to require a revision.

Particularly the North American fauna has, by the indefatigable studies especially of BARNES, MC. DUNNOUGH, BENJAMIN and LINDSEY so entirely been overthrown in contrast to the basis used in DYAR's Catalogue, that it has an entirely different aspect now. The types of many species have quite wrongly been determined. Thanks to the kind aid of the gentlemen mentioned above — especially Mr. FOSTER, H. BENJAMIN in a most disinterested way put at our disposal a great deal of literature and typewritten notes. — we are able to-day to supply a considerably better survey. Still we are aware that many, particularly of the tropical species, being but insufficiently known or described according to single specimens, have been wrongly ranged with us or are synonyma. For corrections that may serve for later supplementary data we shall always be obliged.

Genus **Pyrrhopyge**.

For *P. araxes* Hew. (p. 839, t. 162 e) together with *arizonae* G. & S. a new genus has been established by LINDSEY: **Apyrrothrix**, chiefly founded on the somewhat different shape of the wings.

Genus **Mimoniades**.

chanchamayonis. *M. pityusa* Hew. (p. 846, t. 164 a). — The f. **chanchamayonis** Strd. has on the forewings somewhat broader, on the hindwing narrower light discal bands; both are anteriorly not connected. Near the margin of the hindwing 4 or 5 bluish sublimbal spots. From the Chanchamayo (Peru).

mapirica. *A. pardalina* Fldr. (p. 847, t. 164 g). — The form **mapirica** Strd. is distinguished by a narrower, uni-coloured, bluish-black marginal band of the hindwing and more distinctly separated subapical spots of the forewing. From the Rio Mapiri.

Genus **Myseelus**.

rogersi. **M. rogersi** Kaye is to be inserted on p. 848 after *M. orthrus*. It forms the intermediary between *orthrus* Hew. and *phoronis* (165 a), being more allied to the latter from which it differs by white instead of yellow hyaline spots. The veins are scarcely marked, black, beneath the yellow scaling is strongly reduced; by a broad black band the lemon-coloured basal part is separated from the quite brown distal half. Expanse of wings: 57 mm. Trinidad.

perissodora. **M. perissodora** Dyar is to be inserted after *M. pegasus* (p. 848, t. 165 b) near which it belongs. Above with a faint bronze lustre, dark red-brown, with black veins and 3 large hyaline spots through the disc, a large, quadrangular one in the cell, a somewhat larger, rectangular one below it, and a triangular submedian one. A subapical bent row of 5 small spots, below them two more. Hindwing with a darker median band. Hindwing beneath black, in the basal half light yellow, at the proximal margin with a black spot. Expanse of wings: 52 mm. Described from Mexico (Misantla, in June).

Genus **Phocides**.

Ph. lilea Reak. (p. 850, t. 165 d) is said to have been taken in 1 specimen in Texas.

To *Ph. batabano* Luc. (p. 851, t. 165 d) add as another synonym: (= okeechobee Worth).

Genus **Eudamus**.

For this genus (p. 852 to 858 and t. 160, 161), according to the more modern conception of the rules of priority, the older name of the genus: **Goniurus** Hbn. ought to be placed, with the type *simplicius* Stoll, which the American authors only apply for the group of *proteus-dorantes-simplicius-eurycles*. — For the group of *albofasciatus-zilpa* LINDSEY established the name of the genus **Chioides**, whereas *alcaeus* beside *melon* is placed into the new genus **Codattractus** Lindsey (*Heteropia* nom. praeocc. H. CARTER [*Sponges*]).

E. dorantes Stoll (p. 853, t. 160 a). — **rauterbergi** (not *rautenbergi*!) is a small dark form from Texas *rauterbergi*, and Arizona.

E. simplicius Stoll (p. 855, t. 160 e) and *E. eurycles* Latr. (ibid.) are 2 separate species, *simplicius* with and *eurycles* without a costal fold.

Genus **Epargyreus**.

E. tityrus F. (p. 860, t. 166 e). Add to it: ab. **obliteratus** Scddr. has instead of the discal band *obliteratus*, only 3 small roundish spots and only 1 subapical spot; beneath on the hindwing the silvery colour is more extensive.

E. zestos Hbn. (p. 861, t. 166 g). Hereto add as synonym: (= oberon Worth.). The species flies in Florida in August and September.

Genus **Acolastus**.

The genus must be named **Polygonus** Hbn., since *Acolastus* is preoccupied (Coleoptera).

A. amyntus F. (p. 862, t. 166 g) occurs in the form **arizonensis** Skinn., being above and beneath lighter *arizonensis*, to the north as far as Texas and Arizona.

Genus **Telegonus**.

T. elorus Hew. (p. 863, t. 167 b). Here another synonym (= subblasius Strd.) is to be added as well as another habitat: Argentina.

T. hahneli Stgr. (p. 863, t. 167 b, c) is also mentioned from North America (Arizona).

Genus **Protopenes**.

P. extrusus Fldr. (p. 865, t. 172 d). The species is to be eliminated in this volume. It is described from the Aru Islands and has been dealt with at large in Vol. IX. MABILLE's statement, mentioning the species from Colombia, is certainly a mistake.

Genus **Telemiades**.

T. perseus Mab. & B. (p. 868, t. 172 a). Insert after this species:

T. mnemon Schs. Above dark brown, in the basal half with thick yellowish-brown hair, also near *mnemon*, the anal angle before the margin and behind the cell, in the discal area below the cell tinted bluish-black. Hyaline spots yellowish, a large distally concave one in the cell-end, below it a narrow one, a small one above it farther distally; 3 small subapical spots, below them before the margin 2 more. On the hindwing only the costal margin, a blurred postmedian macular band, and marginal spots remain dark brown, the rest is densely dusted and haired yellowish-brown. Beneath dull blackish-brown, at the proximal margin grey, hindwing dull yellowish-brown with a dark distal margin. Expanse of wings: 28 mm. Costa Rica.

Genus **Rhabdoides**.

Rh. cellus Bsd. & Lec. (p. 871). According to the more modern conception *pseudocellus* Cool. is a distinct species.

Rh. casica H.-Schöff. (p. 871, t. 169 b). Add as synonym: (*orestes* Lintn.)

Genus **Naseus**.

Insert after *N. phocus dianina* (p. 873):

phintias. **N. phintias** Schs. Hereto belongs as the ♀ the insect figured as a variety of *phocus* in the supplement of the „Biologia Centrali-Americana“. Above dark brown, basal area and proximal margin dusted with orange-brown. Spots as in *phocus*, though with another small one between the radial veins. Hindwing quite orange-brown, but at the costal margin and narrowly at the distal margin blackish-brown. Otherwise, also beneath, like *phocus*. Expanse of wings: 55 mm. Costa Rica (Guapiles).

N. euribates Cr. (p. 873, t. 170 a) has recently also been reported from North America, the correct name of the species being *hesus* Ww. & Hew. (nec. Dbl.); *euribates* Cr. is very doubtful. As another questionable synonym add: *etias* Hew.

Genus **Murgaria**.

Insert after *M. albociliata* Mab. (p. 875, t. 170 c):

coyote. **M. coyote** Skinn. In the exterior hardly discernible from the preceding species; fringes of hindwings more or less intensely striped brown, in *albolineata* only at the apex and anal angle, in the centre they are always purely white. The genital organ, however, is quite different in both. Texas and Arizona.

Genus **Cogia**.

Insert between *C. hippalus* Edw. and *C. calchas* H.-Schöff. (p. 877, t. 170 e):

outis. **C. outis** Skinn. Ground-colour dull brownish-black like in *hippalus*, the forewing usually with 2 postdiscal hyaline spots between and above the median veins and distinct subapical spots whereby the species differs from the otherwise very similar *calchas*. Texas in August.

Genus **Thorybes**.

nevada. **Th. nevada** Scddr. being on p. 880 placed as a synonym to *Th. mexicana* H.-Schöff. has of late been regarded as a distinct species with *aemilea* Skinn. as synonym. In the exterior both are quite the same, but the genital organ is said to be constantly different. The valve of *mexicana* has a convex end and is only very feebly serrate, that of *nevada* has a concave end and is strongly dentate. Furthermore add after *mexicana*:

confusis. **Th. confusis** Bell. resembles *pylades* Scddr. so much that it is hardly discernible, and mixed up with it in most of the European collections; the ♂ is easily distinguished by the absent costal fold. The genital organ is very different by *confusis* having the bipartite uncus of the *pylades*-group and the penis of *Cogia calchas*, thus connecting the two genera to a certain extent.

Th. mysie Dyar (p. 880, t. 171 b, c) is also known from Arizona and is placed to the genus *Phaedinus* by LINDSEY.

immaculata. *Th. pylades* Scddr. (171 b) being on p. 880 placed to the genus *Cocceius* belongs to *Thorybes*. Add hereto yet: ab. **immaculata** Skinn. in which the hyaline spots are almost extinct. Also the species following *pylades* (p. 880): *drusius* Edw. has of late been placed to the genus *Thorybes*.

Genus **Hydraenomia**.

nebulosa. **H. nebulosa** sp. n. (178 b) is to be inserted after *H. orcinus*, p. 881. Larger and with broader wings than *orcinus*, but in the anatomical marks well fitting to it. Light greyish-brown, covered with long olive hair-scales, rather thinly scaled, disc of the hindwing partly sem-transparent. Forewing almost with the same hyaline spots as *orcinus*, but the cellular spot is divided into 2 long parallel ones, the one behind it is ⊔-shaped with very long, narrow sides. Beneath the same, but without the long hairing. The hindwing in the disc shows a large white, semi-transparent spot extending from the costal margin to the inner-marginal fold. 1 ♂ from the Songo (Coll. FASSEL).

H. zelotes *Hew.* (178 b) has longer hindwings than *orcinus* with a large, creamywhite discal spot; *zelotes*. in the marginal area, being covered with long, greyish-yellow hair-scales, there are black submarginal spots. On the forewing the similarly arranged hyaline spots are almost three times as large as in *orcinus*. Brazil (São Paulo).

H. aberrans *spec. nov.* (178 b) is on the whole somewhat like *zelotes*, the discal spot of the hindwing *aberrans*. much smaller and rounded. On the forewing the cellular spot and the spot below it form a broad band, the inner-marginal spot is reduced to a dot; the other hyaline spots are quite similarly arranged. The abdomen is white-haired as in *zelotes*, as well as the proximal margin of the hindwing. Described according to 1 ♂ from Tefé of the Coll. SEITZ.

Genus **Ate.**

Insert after *A. proxenus* (173 g) on p. 889:

A. canace *Schs.* (189 a). Similar to *proxenus*; the blackish-brown wings exhibit only subcostally in *canace*. the middle one minute hyaline dot and 2 subapical ones, the lower of which is removed proximally. The distal margin of the hindwing is broad blue from the upper radial vein to the proximal margin; costal margin and apex dull blackish-brown; a similarly coloured arcuate stripe from the lower median vein to the anal angle. Expanse of wings: 23 mm. Carillo (Costa Rica).

Genus **Pellicia.**

Insert after *P. dimidiata* (174 c) on p. 892:

P. olinda *Strd.* Distinguished from *dimidiata* by the palpi being also beneath dark and by quite *olinda*. black legs and tarsi. From Olinda (Brazil). It is doubtful whether it is a separate species.

Genus **Cyclosaemia.**

Insert between *C. elelea* and *luthaea* (174 i) on p. 895:

C. subcaerulea *Schs.* is likewise allied to *jacobus* and *elelea*, easily recognizable by the upper surface *subcaerulea*. showing metallic lustrous green costal margin, distal margin and veins in the apical part on a greyish-brown ground; marking as in *jacobus*, but without the 3 subapical spots; the discal eye-spot contains 2 bluish-white pupils. Beneath the forewing shows a green reflection, at the proximal margin it is grey. Hindwing of a bright blue, at the costal margin, apex and fringes brown. Expanse of wings: 31 mm. Costa Rica.

Genus **Echelatus.**

Insert after *E. sempiternus* (175 a) on p. 896:

E. depenicillus *Strd.* is easily separated from *sempiternus* and *varius* by the anal part of the hind- *depenicil-* wing beneath not being lighter. Described according to a ♂ from Colombia. Probably the insect corresponds *lus*. with *robigus* *Plötz* (175 a).

E. lucina *Schs.* (192 a) is easily separated from the other species by its metallic lustrous green head and *lucina*. collar. The blackish-brown forewing with a purple reflection exhibit dark antemedian and postmedian nebulous bands, the latter being bent above the lower radial and from there straight vertical to the proximal margin. Hindwing similar, but less reflecting purple, more intensely only in a stripe below the cell from the base to the distal margin. Beneath lighter brown with a whitish-grey base of the proximal margin. Expanse of wings: 37 mm. Guapiles (Costa Rica).

Genus **Mylon.**

Insert after *M. lassia* *Hew.* (175 c) on p. 897:

M. puncticornis *Strd.* differs from the allied species by only 3 subapical dots. Ground-colour dingy *puncticor-* white, dusted with grey and brown, only in the discal area of a purer white. Basal area black, with yellow *nis*. hairs and scales, distinctly dentately defined with a black cell-end streak, behind it blackish with 2 or 3 quite blurred lighter macular bands; in the cell with a small dark spot and below the transverse vein traces of a grey blurred band resting vertically on the proximal margin. Marginal area of hindwing 2 mm broad light greyish-brownish, with a darker marginal line and similar small submarginal spots, before them another darker, blurred, broken transverse band. In the middle besides 2 grey lines. Beneath white with fine dark transverse streaks corresponding with the markings above. Antennae black with light dots. Expanse of wings: 30 mm. According to 1 ♂ from Colombia.

Insert after *M. pelopidas* F. on p. 897:

brasilicola. **M. brasilicola** Strd. (? = *decens* i. l.) (178 b, as *decens*). Whitish, densely dusted with grey, on the hindwing less so; the forewing shows a deep brown antemedian band being broader at the costal margin and ending pointed at the proximal margin, distally undulate; a postdiscal transverse line is proximally defined on the lower radial vein and above it inside broadly dusted with brown; in front of it below the costal margin a small white hyaline dot; an antemarginal brown line is towards the apex broadly triangular. Hindwing in the basal quarter more densely dusted with grey, distally bordered by a dark line, with a fine postdiscal transverse line and faint traces of an antemarginal line. Beneath somewhat lighter, marked the same, but the forewing is without the brown antemedian band, and at the anal angle of the hindwing is a round dark spot. South Peru, Brazil.

Genus **Xenophanes**.

H. tryxus Cr. (p. 898, t. 175 c) has also been taken in Texas (Brownsville) in July.

Genus **Eantis**.

E. thraso Hbn. (p. 902, t. 176 b). We add hereto as synonym: *tamenund* Edw. The species was also taken in Texas in May and July.

Genus **Staphylus**.

St. brenus G. & S. (p. 905, t. 176 f) is said to occur also in the southern part of North America. *arizonensis*. — The form **arizonensis** Mab. & B. will probably be the northern form, but unfortunately no particulars about it were to be obtained.

Add to p. 905, line 8 from below:

sodalis. **St. sodalis** Schs. (189 a) is very closely allied to the preceding, it is smaller, also the spots are smaller, the distal ones in a dentate, oblique line. Expanse of wings: 29 mm. El Alto (Costa Rica).

Add to p. 906, line 19 from below:

machuca. **St. machuca** Schs. (189 i) seems to be allied to the preceding, but it has 3 small subapical dots; in the lighter distal margin of the forewing there are between the veins darker marginal spots. Beneath the costal margin is scaled iridescent green; basal half and proximal margin of hindwing strewn with whitish. Throat white. Anterior femora grey. Expanse of wings: 26 mm. Costa Rica.

Genus **Timochares**.

T. trifasciatus Hew. (p. 907, t. 177) also occurs in the southern part of North America.

Genus **Miltomiges**.

Add to the end of the genus on p. 911:

verticalis. **M. verticalis** Plötz. Above brown with a broad chestnut-brown costal margin in the basal half and anterior body, fringes reddish-brown. On the forewing a strangulated cellular spot is fused with the postdiscal spot below it, farther distally above it 2 more spots. Beneath the apex of the forewing is broad red-brown like the hindwing; the latter is densely strewn with a lilac grey at the distal margin and in the basal half except the costal margin, so that a broad median band remains brown. Brazil.

commodus. **M. commodus** Plötz is similar, the spots are smaller, the cellular spot is absent. Also beneath very similar, but much more variegated, of a brighter red and violet with the smaller spots. Brazil. SCHAUSS in describing *Carystus subrufescens* (p. 981) states that the species is closely allied to *commodus*, both may therefore belong to *Carystus* or to this genus.

Genus **Pholisora**.

Add to *Ph. alpheus* Edw. (p. 913, t. 177 i) as synonym: *oricus* Edw. — For *alpheus*, *libya* and its *lena*, paler though intensely spotted form **lena** Edw. a separate genus was established by DYAR: **Hesperopsis**.

Genus **Chiomara**.

Ch. gesta H.-Schöff. (p. 913, t. 178 a). As another synonym *llano* Dodge is yet to be added. — This species is now placed to *Thanaos*, next to *lacustra* (178 i) and *burgessi*.

Genus **Heliopetes**.

H. domicella Erichs. (p. 914, t. 178 c). Another synonym is to be added: *nearchus* Edw.

H. nivella Mab. (p. 914, t. 178 d) also occurs in Texas where it flies in June.

H. laviana Hew. (p. 915, t. 178 e) also flies in Texas in June and July. The genus *Heliopetes* is, moreover, cancelled by LINDSEY since there are no anatomical marks of distinction from *Hesperia* F. (which has recently been named *Erynnis* Schrk.). The species would therefore have to be combined by the latter name. — To *ericetorum* Bsd. (178 f) add as synonym *alba* Edw. But *ericetorum* itself is to be regarded as a distinct species.

Genus **Thanaos**.

Instead of this name the older name of the genus **Thymele** F. would have to be placed.

In *Th. icelus* (p. 916) the author's name *Lintn.* is to be changed into *Scddr. & Burg.*

Th. somnus Lintn. (p. 916, t. 178 g) is to be placed as a form to *brizo* Bsd. & Lec. (178 f). — *callidus* Grinn. (part.) is the synonym of it. — Insert after *somnus*:

Th. burgessi Skinn. is very similar to *lacustra* Wright (p. 917, t. 178 i) which has to be ranged here, *burgessi*. it is on an average somewhat larger and has beneath at the apex of the forewing a light violet patch distinctly contrasting with the ground-colour and being absent in *lacustra*. The genitals are in both very different. Arizona, New Mexico.

Th. lucilius Lintn. (p. 916, t. 178 g) is a form of *persius* Scddr. (ibid.), as well as *afranius* Lintn. (ibid.) and **pernigra** Grinnell nec Wr. (p. 917) being the very dark race of the Pacific coast. Insert after *pernigra*. *lucilius*:

Th. callidus Grinn. (= *lilius* Dyar) is in the female marked like *brizo* (178 f), whereas the ♂ shows *callidus*. a very small white discal spot, 3 small white subapical spots and a rather large white spot in the middle of the marginal area. The genital organ resembles that of *pacuvius*. Brit. Colombia, California.

P. 916, line 25 from above: place *ausonius* as „aberrat.“ to *zarucco* (line 19 from below).

Th. juvenalis F. (p. 916, t. 178 g). Add as another (doubtful) synonym: *plautus* Scddr. & Burg.

Th. propertius Lintn. (p. 916, t. 178 h). Hereto add as synonym: (= *tibellus* Scddr. & Burg.); and besides: f. **borealis** Cary as a dark race with very much reduced light spots, from the Mackenzie. *borealis*.

Th. petronius Lintn. (p. 916, t. 178 g) is to be placed as a synonym to the following *horatius* Scddr. (178 h), and

Th. naevius Lintn. (p. 917, t. 178 h) belongs as a synonym to the preceding *terentius* Scddr. (p. 916). — Insert after *pacuvius* Lintn. (p. 917, t. 178 h):

Th. scudderi Skinn. (= *pacuvius* G. & S. nec Lintn.) in its exterior is not discernible from *pacuvius* Lintn. The genital organ is very different: the right valve has outside an almost twice as long and broad appendage and on the inside there is only a very small projection, in *pacuvius* a very long distally bent hook. From Texas and Arizona (July, August).

Th. clitus Edw. (p. 917, t. 178 h). Add hereto as synonyms: *maestus* G. & S. (p. 917) and *tatius* Dyar nec Edw. — *tatius* Edw., however, is to be placed as a form to *tristis* Bsd. (p. 917) as well as *clitus* Dyar nec Edw.

Genus **Melanthes**.

M. brunnea H.-Schöff. (p. 918) from the Antilles has also been taken in Florida.

Genus **Hesperia**.

As the name of the genus for the species belonging hereto, the name *Erinnys* Schrk. has been of late proposed.

H. syrichthus F. (p. 918, t. 178 k). As has been mentioned in the first passage on p. 919, *montivagus* Reak. (= *fumosa* Rev.) (178 k) has to be placed as the synonym or perchance as an insignificant, somewhat darker form to *syrichthus*, as the type in the Coll. STRECKER shows.

H. centaureae Rmb. (p. 918). Here the name *ruralis* Bsd. as a synonym is to be eliminated and placed behind the latter as a distinct species with the synonyms: *caespitalis* Bsd., *ricara* Edw., *petreius* Edw. (p. 919). It is a smaller and darker species than the preceding, distributed from Alberta to Texas.

H. xanthus Edw. (p. 919, t. 179 a). Insert here: f. **macdunnoughi** Obth. is only half as large with somewhat smaller spots slightly more distinctly and clearly contrasting with the purer dark ground. From Arizona.

The species called *H. montivaga* (p. 919) must be named: *tessellata* Scddr.

Insert between *D. gyrans* Plötz (p. 924, t. 180 a) and *microsticta* G. & S. (p. 925, t. 180 a):

Genus **Dalla**.

D. pirus. *D. pirus* Edw. (= *semicaeca* M. & B.). Above dull blackish-brown, marked as in *polingii*, but with smaller, partly quite absent spots. Hindwing without spots. Beneath lighter brown, the forewing in the disc somewhat blackened; 3 minute subapical spots close together in one line with 2 below the lower cell-angle. Utah, Colorado.

Genus **Pamphila**.

BARNES and MC DUNNOUGH propose to replace this name by: *Carterocephalus* Led.

P. floridae Mab. (p. 926) is to be cancelled here; the name is to be placed as a synonym to *Lero-dea eufala* Edw. (p. 941, t. 182 k).

Genus **Oarisma**.

O. edwardsii Barnes. To this species the description has yet to be added. Above bright golden yellow, fringes proximally dark brown, distally lighter. Beneath the forewing is yellowish, except the proximal margin being shaded with blackish. Hindwing greyish-yellow, in the anal third yellow. Described according to 1 ♂ from Denver (Colorado).

Genus **Ancyloxypha**.

A. longleyi French (p. 927) is to be placed to the preceding *numitor* (p. 927, t. 180 e) of which it is merely a form with a lustrous bluish-black upper surface.

Genus **Copaeodes**.

C. wrightii Edw. and *eunus* Edw. are to be placed into the following genus *Chaerephon*; before *Ch. rhesus* Edw. (p. 928, t. 180 e).

C. myrtis Edw. is to be cancelled as a species and the name to be placed as a synonym to *Ancyloxypha arena* Edw. (p. 928, t. 180 e).

To *C. singularis* H.-Schäff. (p. 928, t. 180 d) add as another synonym *nanus* Wts., and insert after this species:

C. rayata. **C. rayata** B. & McD. (= ♀ *procris* Edw. (part.), *waco* Plötz nec Edw., *aurantiaca* G. & S.). This small species resembles *arene* (180 e) above, but beneath it is easily discernible by a white ray of the hindwing extending from the base through the cell to the distal margin, the other cell-spaces being also striped whitish. Expanse of wings: 18 to 20 mm. Texas to Mexico.

Genus **Chaerephon**.

Beside the above mentioned species *Copaeodes wrightii* Edw. (180 d) and *eunus* Edw. (180 e), also *Erynnis carus* Edw. (p. 930) and *Stomyles simius* Edw. (p. 943, t. 193 b) have recently been inserted in this genus.

Genus **Erynnis**.

As the name *Erynnis* has to supersede the genus having hitherto been known as *Hesperia* in the literature, BARNES and MC DUNNOUGH have proposed to designate the former *Erynnis* as genus *Hesperia*. The arrangement of the species differs so entirely in the position and synonymy from the former arrangement by DYAR that we prefer to follow the arrangement stated by A. W. LINDSEY and according to the latest researches by Mr. F. H. BENJAMIN; in order to facilitate this, we add the number of pages and lines of our former treatment.

H. uncas Edw. (= *ridingsii* Edw. [p. 930, line 24 from below], ♀ *axius* Plötz [p. 930, line 20 from below]).

H. lasus Edw. p. 930, line 25 from above.

H. licinus Edw. p. 930, line 4 from below.

H. meta Scddr. p. 930, line 24 from below.

H. morrisoni Edw. (= *morrisoni* Plötz) p. 931, line 1 from above.

H. columbia Scddr. (= *sylvanoides* Scddr. [p. 934, line 1 from above], *california* Wright, *crynnoioides* Dyar (p. 931, line 6 from below)), p. 929, line 2 from below.

H. cabelus Edw. p. 930, line 29 from above.

H. harpalus Edw. p. 930, line 12 from above.

H. comma L. p. 929, line 14 from below.

— f. *colorado* Scddr. (line 4 from below). Under surface bright green, the band purely white, short, the basal spots united in the shape of a U.

— f. *manitoba* Scddr. (= *laurentina* Lyman [p. 930, line 2 from above]) p. 929, line 13 from below. Beneath golden brown with white spots.

— f. *idaho* Edw. p. 929, line 6 from below.

— f. *assiniboia* Lyman p. 930, line 1 from above.

— f. *oregonia* Edw. p. 929, line 1 from below. Beneath like the preceding but the band yellowish instead of white.

H. juba Scddr. (= *comma* Bsd.) p. 929, line 9 from below.

H. woodgatei Willms. was described as a form of *juba*, but it seems to be a distinct species which is very similar to *juba*, but shows much smaller spots; the under surface is generally dark, scantily strewn. Arizona, Texas, New Mexico, taken in September and October.

H. viridis Edw. p. 929, line 10 from below is a distinct species.

H. nevada Scddr. p. 929, line 7 from below, is also a distinct species; it flies from North Canada to Arizona.

H. ruricola Bsd. p. 939, line 16 from below.

H. attalus Edw. p. 930, line 15 from below.

— f. *seminole* Scddr. (= *quaiapen* Scddr., *slossonae* Skinn., *attalus* Holl.) is above and beneath very dark; the ♂ has smaller spots and on the forewing beneath but very little reddish-yellow; the ♀ has quite whitish spots and beneath no reddish-yellow at all.

H. horus Edw. (p. 968, line 2 from below) owing to the stout antennal club with a short point does not belong to *Lerema*, but hereto; as, however, only 1 ♀ is known, its position remains uncertain; it is perhaps merely a melanotic specimen of another species (*attalus* or *leonardus*).

H. leonardus Harr. p. 934, line 19 from above.

H. meskei Edw. (= *straton* Edw.) p. 934, line 23 from above.

H. ottoe Edw. p. 930, line 21 from above.

H. pawnee Dodge (= *ogallala* Leussler) p. 930, line 17 from above.

— f. *montana* Skinn. (line 19 from above).

H. sassacus Harr. p. 930, line 6 from above.

— f. *dacotae* Skinn. p. 930, line 9 from above.

— f. *manitoboides* Flesch. p. 930, line 4 from above. *napa* Edw. p. 930, line 25 from below belongs to *Augiades* as the Colorado-form of *sylvanoides* (p. 934, t. 181 f, g); it is larger and beneath less variable.

yuma Edw. p. 930, line 11 from below, likewise belongs to *Augiades* (p. 939) with the synonym: *scudderi* Skinn. (p. 936, line 6 from below).

carus Edw. p. 930, line 8 from below, as stated under *Chaerephon*, belongs to this genus (p. 928) after *Ch. rhesus*.

Genus **Thymelicus**.

brettus Bsd. & Lec. (p. 931, line 16 from below) is placed to the genus *Politis* (p. 932) by BARNES and MC DUNNOUGH, also the following species *mystic* (line 9 from below) with *dacotah* Edw. (= *pallida* Skinn.) (p. 930, line 25 from below) as a form of it. — ab. **weetamoo** Scddr. and ab. **nubs** Scddr. are both darkend melanotic female forms. *weetamoo*,
nubs.

chusca (p. 932, line 4 from above) and *draco* (ibid. line 8) are likewise to be placed to *Polites*, the former as a form of *Pol. sabuleti* Bsd. (p. 932, t. 181 d).

siris Edw. (p. 932, line 11 from above, t. 181 b) is to be placed as a synonym to *sonora* Scddr. (p. 934, line 1 from above, as *sylvanoides*) and comes to the

Genus **Polites** (p. 932).

tecumseh. *chispa* Wr. (p. 932, line 8 from below, t. 181 d) is to be replaced by the older name **tecumseh** Grinnel; it comes as a form to *sabuleti*, whilst the name *chispa* Wr. becomes synonymous.

Genus **Catia**.

C. druryi Latr. (p. 933, line 13 from above) has to be replaced by the older name *otho* with ABBOTT and SMITH as authors.

Genus **Ochlodes**.

Line 4 from below:

To *nemorum* comes *verus* Edw. of p. 934, line 23 from below, as a synonym and *pratincta* Bsd. of p. 934, line 26 from below, as a form, whereas *yreka* Edw. is to be transferred to *agricola* Bsd. line 6 from above.

P. 934, line 1 from above, instead of the synonym *sonora* place the two following *agricola* Bsd. (= *francisca* Plötz) as synonyma.

Line 9 from above: *snoëi* Edw. is to be placed to *Augiades* (p. 939).

Lines 19 and 23: *leonardus* Harr. and *méskei* Edw. are to be ranged in the genus *Hesperia* after *horus* Edw.

Genus **Limochares**.

L. bimacula Grt. & Rob. p. 934, line 14 from below, is to be placed to the genus *Euphyes* (p. 935).

Line 10 from below: *pontiac* Edw. becomes synonymous to *conspicua* Edw. which name has the priority.

rhena. Line 7 from below: place *manataaquia* to the genus *Polites* (p. 932). Add as a form of it: **rhena** Edw. (= *alcina* Skinn.) being a lighter, western race from Colorado.

Line 2 from below: *yehl* Skinn. belongs into the genus *Paratrytone* p. 936.

Line 3 from above: *dion* belongs into the genus *Euphyes* (p. 935), as well as *arpa* (line 6) and *palatka* (line 8).

alabamiae. To *L. dion* (p. 935, line 3 from above) add as a form: **alabamiae** Linds. The reddish-yellow colour of the upper surface is reduced to a single subapical spot, a small stripe in the lower cell-end and a small spot behind it, which is followed by some more along the distal edge of the scent-spot; on the hindwing the reddish-yellow colour is also reduced. Beneath darker than *dion*; instead of the macular band there are only 3 small spots behind the stigma; the 2 light rays contrast less with the ground-colour. Alabama. Insert after it:

dukesi. **L. dukesi** Linds. like *dion* shows on the hindwing beneath 2 light rays; it is much darker beneath, and the spots of the forewing are absent altogether. Above the reddish-yellow is much darker, also on the disc of the hindwing, on the forewing it is only present as a small spot behind the stigma. Alabama.

L. byssus Edw. (p. 935) with a doubtful synonym (? = *bulenta* Bsd. & *Lec.*) belongs to the genus *Atrytone* Scddr. (p. 937).

Insert after it:

kumskaka. **kumskaka** Scddr. is a questionable species from Iowa, which was hitherto regarded as *conspicua* Edw. It seems to be very closely allied to *byssus* (181 k), if it is not to be regarded merely as a local form of this species only known from Florida.

L. cernes Bsd. & *Lec.* (p. 937, line 18 from above) is to be ranged with the genus *Polites* (p. 932), but it becomes synonymous to *thauwas* F., with the other synonym *phocion* F.

Genus **Euphyes**.

E. metacomet Harr. (p. 935) becomes synonymous to *vestris* Bsd. which name has the priority, to which also *osyka* Edw. (p. 935, t. 182 a) is to be added.

E. verna Edw. (p. 935, t. 182 a) belongs into the genus *Atrytonopsis* (p. 940).

Genus **Oligoria**.

To *O. maculata* Edw. (p. 935, t. 181 a) add as another synonym: *norus* Plötz.

Genus **Atrytone**.

delaware Edw. (p. 937, line 12 from above, t. 182 c) becomes synonymous to *logan* Edw. which name has the priority. Add to it: f. **lagus** Edw. as the western race with a very light under surface.

zabulon and *hobomok* (p. 937, lines 17 and 22) belong into the genus *Poanes* (p. 936), also *melane* Edw. (p. 938, line 17 from above) and *taxiles* Edw. (p. 939, line 20 from below).

A. arogos Bsd. & Sec. (p. 939, t. 182 g). Add yet as synonym: *vitellius* Abb. & Sm.

A. streckeri Skinn. is to be placed as a synonym to *Choranthus radians* Luc. (p. 941) which species has of late been placed to *Euphyes* (p. 935) beside *dukesi* and *dion*.

A. ruricola Bsd. belongs to the genus *Hesperia* (formerly *Erynnis*) between *juba* and *attalus* (p. 930).

Genus **Atrytonopsis.**

Into this genus, between *hianna* (p. 940) and *judas* (p. 941) belong yet *A. loammi* Whitney (= *regulus* Edw.) of p. 968, line 7 from below and *lunus* Edw. (p. 969, line 1 from above).

vierecki Skinn. resembles *deva* (182 h), but it is smaller, lighter and greyer, with 2 occasionally connected spots in the cell-end of the forewing and a more distinct stigma. New Mexico, in June.

cestus Edw. is very closely allied to *python* Edw. (182 i), but larger, the spot between the median veins of the forewing very large and triangular. Hindwing beneath watered with purple blackish, the spots semi-diaphanous. Only the type from Arizona seems to be known.

edwardsi B. & McD. Above deep blackish-brown, base of forewing and costal margin scaled yellow, hindwing in the basal half haired yellow. Forewing with a large, quadrangular hyaline spot in the cell, 3 minute subapical spots and 3 postdiscal ones, the lowest being small and triangular, the middle one very large and quadrangular. Hindwing with a small white cellular spot and 3 behind it, the uppermost being the largest. Beneath the apex of the forewing and the hindwing are dusted with a bluish grey, the hindwing beside the spots of the upper surface with 3 whitish basal spots. Expanse of wings: 30 to 35 mm. Arizona.

To *python* Edw. (182 i) belongs f. *margarita* Skinn. being the race from New Mexico, which is beneath on the hindwing less contrasting, the spots distally not shaded with brown. Above the spots are not so yellowish as in *python*.

Genus **Lerodea.**

Before *eufala* p. 941, line 18 from above, insert: *arabus* Edw. of p. 943, line 28 from below.

Genus **Amblyscirtes.**

Line 19 from below: *eos* (p. 942) becomes a synonym to *alternata* Grt. & Rob. which name is to be cancelled with *samoset* (p. 943, line 5 from above), and add as another synonym: *meridionalis* Dyar.

Genus **Stomyles.**

St. cassus Edw. (p. 903), *comus* Edw. to which species the name *quinquemacula* Skinn. (of *Pamphila* p. 927, line 1 from above) belongs yet as synonym, as well as *hegon* Scddr. (*samoset* Scddr. becomes synonymous) are of late ranged with *Amblyscirtes* (p. 942); so are *nereus* Edw. (183 b, c), *tolteca* Scddr. (183 b), *florus* G. & S., probably also *gallio* Mab. and *pupillatus* Mab. (183 c). The genus *Stomyles* is to be cancelled again. Of the remaining species *fusca* Grt. & Rob. is to be placed to the genus *Megistias* (p. 973) and *ostari* Skinn. to *Mastor* (p. 972).

Genus **Calpodes.**

Place to the end of this genus (p. 944) after *C. ethlius* Cr.:

C. coscinia H.-Schäff. (p. 949, line 25 from above). Specimens from Brownsville (Texas), according to BARNES and MC DUNNOUGH, as well as the Mexican specimens, are better placed to the genus *Calpodes* owing to the spined middle tibiae. It is not impossible that FELDER in the description of his *ares* has had another species before him with unspined tibiae, for which reason the insect will for the present be better ranged by HERRICH-SCHÄFFER's name.

Genus **Mastor.**

bellus and *phylace* (p. 972, t. 187 g) are nevertheless 2 separate species; the former is found in North America in the mountains of South Arizona and has two breeds (in May, June, and the second in July) being entirely alike, whereas *phylace* occurs in South Colorado and New Mexico and probably yields but one breed in June. The scent-spot is in both species different: in *bellus* long and narrow, in *phylace* shorter and more compact.

To *anubis* (line 24 from below) add as another synonym: *bicolor* Mab.

List

of the new species and varieties described in vol. 5.

- abdonides* (Cyclosma) *Draudt* 978.
aberrans (Hydraenomia) *Draudt* 1019.
aberrans (Phyc. actæina) *Röb.* 448.
abrupta (Phyc. claphiaea) *Röb.* 439.
abulonia (Prep. omphale) *Fruhst.* 562.
abylina (Adelpha abyta) *Fruhst.* 524.

List of Errata of Volume 5.

- P. 3 line 19 from above, after *Glaucoipsis* add: (older name for many Syntomidae).
- P. 4 line 26 from below, for *leucodrosyme* place: *leucodrosime*.
- P. 6 line 28 from below, for *Halesidota* read: *Halisidota*.
- P. 26 line 21 from below, after **turnus** place: *L*.
- P. 42 line 24 from above, after **P. orthosilaus** Weym., for (16 c) read: (16 a).
- P. 46 line 10 from below, after *Doubl.* insert: (17 c).
- P. 55 line 14 from below, for (18 a) place: (18 a, 194 a).
- P. 55 line 3 from below, after *theodice*, for *Bl.* place: *Blch.*
- P. 56 line 24 from above, for Tropeolum read: Tropaeolum.
- P. 57 line 16 from above, after **stigmadice** Stgr. insert: (194 a).
- P. 57 lines 7 and 6 from below, for *evonina* read: *evonima*.
- P. 58 line 23 from below, after **sublineata** Schaus cancel: (19 a).
- P. 62 line 28 from below, for *D.-H.* read: *Dbl. & Hew.*
- P. 65 line 11 from below, for **autodyca** read: **antodyca**.
- P. 66 line 11 from above, after **phalera** cancel: (21 b).
- P. 71 line 8 from above, after *philomene* Stgr. i. l. insert: (194 c).
- P. 71 line 17 from above, for **teutanis** read: **teutamis**.
- P. 71 line 11 from below, for **troezene** place: **affinis**.
- P. 74 line 21 from below, after *susiana* Hpffr. insert: (194 c).
- P. 82 line 14 from below, for *Ménétrie's* read: *Ménétries*.
- P. 84 line 17 from above and lines 15 and 18 from below, for **eleathea** read: **elathea**.
- P. 86 line 6 from above, for (25 c) place: (25 b).
- P. 86 line 17 from above, for (25 b) place: (25 c).
- P. 88 line 11 from below, for (26 g) place: (24 g).
- P. 92 line 11 from below, for (27 d) place: (27 e).
- P. 95 line 14 from below, cancel the reference (28 a).
- P. 104 line 13 from below, for *Heterosais* — read: *Heteroscada* —.
- P. 107 column a, line 9 from below, for **brevos** place: **brephos**.
- P. 119 line 15 from above, for **bomplandi** place: **bonplandi**.
- P. 121 line 26 from above, before *hippothous* insert: *Heliconius*.
- P. 126 line 19 from below, for forewing read: hindwing.
- P. 144 line 3 from below, after **anchiala** Hew. insert: (38 c).
- P. 192 line 17 from below, for **reinoldsi** place: **reynoldsi**.
- P. 201 line 30 from above, for (47 e) read: (47 c).
- P. 208 line 21 from below, for **spartaesus** read: **spartacus**.
- P. 219 line 24 from above, for **sericella** read: **sericeella**.
- P. 221 lines 1 and 2 from above, for **agaya** read: **ayaya**.
- P. 231 line 4 from above, for *Thlg.* read: *Thbg.*
- P. 234 line 6 from above, for **milesi** read: **nilesi**.
- P. 242 line 4 from above, for (51 f) read: (51 g).
- P. 242 line 8 from below, after **tritonina** Edw. insert: (52 b).
- P. 246 line 7 from below, for (51 f) read: (51 g).
- P. 249 lines 16 and 18 from above, for (52 c) read: (52 e).
- P. 253 line 16 from below, for (53 c) read: (53 e).
- P. 264 line 20 from below, for (56 c) read: (56 e).
- P. 264 line 10 from below, for (55 f) read: (56 f).
- P. 268 line 21 from below, for (47 d) read: (57 d).
- P. 268 line 18 from below, for (47 c) read: (57 e).

- P. 270 line 12 from below, after **cothon** *Salv.* insert: (58 c).
P. 293 line 20 from above, for 65 b read: 63 b.
P. 302 line 26 from above, for 61 a ♂; ♀ 61 a read: 61 c ♂; ♀ 61 c.
P. 312 line 21 from above, after *Westw.* insert: (64 b).
P. 328 line 22 from below, after *Fldr.* insert: (62 d).
P. 343 line 8 from below, after *peleides* insert: *Koll.*
P. 350 line 5 from above, after **mellinia** *Fruhst.* insert: (66 b).
P. 355 line 8 from below, for ADAM read: ADAMS.
P. 363 line 23 from above, after **stratonice** insert: *Latr.*
P. 363 line 1 from below, for (81 d, 82 b) read: (82 b).
P. 368 line 1 from below, for (83 c) read: (83 d).
P. 369 line 3 from below, for (82 g) read: (82 f, g).
P. 374 line 27 from below, after **surima** insert: *Schs.*
P. 375 line 1 from above, before Subfamily insert: „2.“
P. 375 line 11 from below, for *E. viculata* read: *H. viculata*.
P. 379 line 17 from below, after **diffusa** *Btlr.* insert: (= *divisius* *Kaye*).
P. 380 line 9 from below, after **schantzi** *Riff.* insert: (72 d).
P. 382 line 4 from above, after **pretiosus** *Weym.* cancel: (32 c).
P. 384 line 24 from below, for *flavifascia* read: **flavifascia**.
P. 384 line 8 from below, for (74 b as *fassli*) read: (74 f as *fassli*).
P. 385 line 19 from below, after **nepelti** *Riff.* insert: (110 A e).
P. 386 line 8 from above, for *hippolyta* read: *hippolyte*.
P. 386 line 27 from below, for *timareta* read: **timareta**.
P. 388 line 21 from above, after **cassandra** *Fldr.* cancel: (76 e).
P. 388 line 6 from below, after **aoede** *Hbn.* cancel: (76 f).
P. 389 line 8 from above, after **faleria** *Fruhst.* insert: (76 e as *aoede*).
P. 389 line 11 from above, for **vola** read: **vala**.
P. 392 line 10 from above, for (77 a) read: (78 a).
P. 397 line 25 from above, for **lybyoides** read: **lybioides**.
P. 398 line 8 from above, to **zorcaon** add: (80 g).
P. 400 line 6 from below, for **telesiphe** *Hew.* read: **tithraustes** *Salv.*
P. 400 line 4 from below, for **tithraustes** *Salv.* read: **telesiphe** *Hew.*

P. 694 line 15 from above, for **hegyas** read: **hegyas**.
P. 698 line 15 from below, for **pedias** *G.* read: **pedias** *Godm.*
P. 698 line 6 from below, after Additions insert: p. 728.
P. 700 lines 30 and 29 from below, for **druryi** read: **duryi**.
P. 702 line 14 from below, after **Metacharis** insert: *Btlr.*
P. 704 line 26 from above, for *Dolm.* read: *Dalm.*
P. 707 line 21 from above, for **glaucobithris** read: **glaucobrithis**.
P. 708 line 14 from below, for **micator** *Schs.* place: *alector*-♀.
P. 710 line 2 from above, for coiling read: angulation.
P. 712 line 2 from below, for **hesperium** read: **hesperinum**.
P. 712 line 2 from below, for **erythroicum** read: **erythraicum**.
P. 713 line 5 from above, for hindwing read: forewing.
P. 713 line 6 from below, after **menalcus** insert: *Stoll*.
P. 717 line 6 from below, for **glaucogonia** read: **glaucoconia**.
P. 718 line 4 from above, after **Pandemos** insert: *Hbn.*
P. 720 line 6 from above, for noticeable above read: hardly noticeable.
P. 722 lines 9 and 18 from above, for (142 h) read: (142 k).
P. 727 line 12 from above, for (110 D f) read: (110 A f).
P. 727 line 15 from below, for **Z. candace** read: **C. candace**.
P. 741 line 20 from above, for *latraillei* read: *latreillei*.
P. 745 line 7 from above, for (146 a, b) read: (146 a).
P. 754 line 18 from above, for (153 b) read: (153 d).
P. 773 line 3 from above, for *Habrodias* read: *Habrodais*.
P. 777 line 22 from below, for (154 d) read: (155 d).

- P. 778 line 22 from below, for **purpurea** read: **purpura**.
P. 784 line 20 from above, after **Schausi**-group add: (Genus **Ipidecla** Dyar).
P. 787 line 3 from above, for (160 d) read: (145 l).
P. 807 line 26 from below, for (160 d) read: (145 l).
P. 817 line 13 from above, for (144 f) read: (144 g).
P. 819 line 9 from below, after **bogotana** f. nov. insert: (144 k).
P. 835 line 24 from below, for *cerealis* read: *cerialis*.
P. 835 line 2 from below, for t. 72 read: t. 75 b.
P. 839 line 12 from above, after (araxes Holl.) insert: (171 g).
P. 839 line 4 from below, for hindwing read: forewing.
P. 841 line 1 from above, for **J. fleximargo** read: **P. fleximargo**.
P. 848 line 22 from above, (165 a) is to be placed after *phoronis*, not after *sothis* Mab.
P. 848 line 16 from below, cancel the reference: (166 c).
P. 853 line 8 from above, for rautenbergi read: rauterbergi.
P. 854 line 20 from above, for (160 e) read: (160 c).
P. 856 line 24 from below, after **undulatus** insert: *Hew.*
P. 857 line 14 from above, after **auginus** insert: *H.-Schäff.*
P. 858 line 15 from above, after **guatemalaina** insert: *Ehrm.*
P. 861 line 5 from above, for *egeus* read: *egens*.
P. 863 line 11 from above, for (172 h) read: (167 b).
P. 863 line 24 from above, cancel (167 d, e), and 16 from below, cancel (167 b).
P. 868 line 11 from above, for *zentus* read: *zeutus*.
P. 870 line 24 from above, after **zonilis** Mab. insert: (168 f).
P. 884 line 21 from above, for (172 f) read: (172 f, g).
P. 884 line 16 from below, after (olena Mab.) insert: (191 h).
P. 908 line 26 from below, for *Brachycorine* read: *Brachycoryne*.
P. 919 line 17 from above, for (178 b) read: (179 b).
P. 927 line 24 from below, for (180 b) read: (180 b, c).
P. 928 line 12 from above, for (180 d) read: (180 c, d).
P. 935 line 23 from below, for (182 k) read: (182 a).
P. 963 line 8 from above, for (186 g) read: (186 f).
P. 972 line 20 from below, for (187 g) read: (187 h).
P. 990 line 18 from below, cancel the reference: (190 f).
P. 1030 line 13 from above, for **Eucorma** read: **Eucora**.
P. 1030 line 17 from above, for „similar“ read: „male“.
P. 1035 line 22 from below, for *compospe* read: *campaspe*.
P. 1065—1088, above the columns read „Pl.“ instead of „Taf.“

Dr. Schlüter & Dr. Mass, Halle on Saale, Germany.

Institute for means of instruction of natural science.

Founded in 1853 by Wilhelm Schlüter †.

*

Speciality of many years standing:

Entomological and Biological Preparations, Collections, Models and Wall-Pictures

in a first class execution at moderate prices.

Own workshops; managed only by experts.

Head-catalogue No. 260 sh. 2.— postfree (for Institutes uncharged).

Utensils for Entomologists.

Publishers of the tables of the «German society for applied Entomology» representing the life and the destroying of noxious insects: composed in cooperation with the best German experts.

Prospectus forwarded on application!

Dr. O. Staudinger & A. Bang-Haas

Founded in 1858.

Dresden-Blasewitz (Saxony).

Founded in 1858.

Bankers: Deutsche Bank, Dresden-Blasewitz.

List of Lepidoptera 58 contains about 29000 species of palearctic and exotic Macrolepidoptera and Microlepidoptera, prepared larvae, 110 pages in large octavo, with a complete list of genera and authors. Price goldmarks 1.50.

List of Series XII contains extremely cheap series (lots), single specimens for private collectors, Museums, in the following divisions:

I. Palearctic Lepidoptera. II. Exotic Lepidoptera. III. Coleoptera. IV. Different Insects. V. Complete Collections. We negotiate the sale of collections of all kinds of insects and have, within the last years, sold a number of very large collections.

VI. Entomological Utensils, Drawers, Cabinets, new and second-hand.

VII. Entomological Library, new and second-hand works.

List of Coleoptera No. 30 (160 pages in large octavo) with about 30000 Coleoptera. Price goldmarks 2.50.

List VII of Different Insects (76 pages in large octavo) with 3200 Hymenoptera, 2400 Diptera, 2200 Hemiptera, 600 Neuroptera and 1100 Orthoptera. Price goldmarks 2.50.

We call the specialists' attention to our also being able to supply many single specimens, aberrations etc. not being mentioned in the price-liste, as well as many species from different and interesting habitats.

Selections of Exotic and expensive Palearctic Lepidoptera at reduced prices are most willingly sent.

Very easy rates of payment. — Monthly instalments.

We are always purchasers of **original returns** from all countries, first class single specimens, collections etc.

Purchase. — Sale. — Exchange.
